Under the conditions enumerated the possibilities for good workers is very great in the R.A.M.C.; they will attain to positions of proper trust and emolument by scientific work. This should much improve recruiting among the officers of the R.A.M.C. But there will almost certainly follow arrangements by which all special medical service will receive higher consideration in the Corps. Not only is there in the work of the Army Medical Department scope for original labour and research in tropical disease, in preventive medicine, and in bacteriology, as well as in the vast clinical field open to the specialist in medicine, surgery, or gynæcology, in venereal disease, in ophthalmology, and so on, but it is proposed to develop a scheme whereby child welfare shall be undertaken systematically by the R.A.M.C. A scheme of this sort is already running successfully at Aldershot, and we see in this direction a fine opening for preventive medicine, and one which should bring the officers of the R.A.M.C. into touch with the soldiers in a valuable and intimate manner.

The above schemes for the stimulation of purely professional work among officers of the Corps must not be taken to imply that instruction in administrative work has been overlooked. One of the lessons of the war was that good administration must exist for the fullest benefit to be obtained from the professional talent available. The necessity of training officers who may display capacity for organisation and administration has not been lost sight of, and there are many appointments of varying degrees of importance and responsibility open to officers who desire to take up this side of the Corps's duties. The inclusion of Officers of the Corps among those officers who are now detailed to undergo courses at the School of Army Administration, Chisledon, is a step of great importance in this connexion.

Rates of Pay and Pension.

The following table shows the

Total Emoluments: Royal Army Medical Corps.

Appointment.	Pay.			Rations.		Servant.		Married and *Unmarried.**

* Rates for unmarried officers in italics.

Charge pay (2*s.* 6*d.*–10*s.* per day) and specialist's pay (2*s.* 6*d.*–5*s.* per day)—i.e., from £45–£180 per annum—in addition for a considerable percentage of officers.

Retirement and Retired Pay.

The following are the rates of pension and retired pay:—

1. Retired pay will consist of two parts: (*a*) a service element based on the officer's total service; (*b*) a rank

THE LANCET.

LONDON: SATURDAY, AUGUST 27, 1921.

The Numbers of the Profession.

At the last meeting of the General Medical Council Sir Donald MacAlister, in his Presidential Address, gave the figures relating to the registration of medical students for recent years, and pointed out that the number of students registered in 1920 was higher than had occurred in any previous year save in 1919, the tendency having been steadily upwards since 1913, when the number was 1480. In 1919 the registration of medical students rose to the abnormal number of 3420, to fall again last year to 2531, but this latter figure is 1000 higher than the figure for 1913, the last complete year before the war. There is no doubt that at last the position is being reached in which there may be a danger to professional education, and perhaps to professional careers, in the mere number of students who are entering. The plea that the medical profession is already overcrowded has often been put forward, but hitherto has not been found sound. Certain obvious professional hardships, generally in relation with salaries or fees, were attributed to overcrowding, but on scrutiny it has been seen, first, that the hardships often had other origin, and, secondly, that the medical profession, having regard to the average size of its membership compared with the figures of the population, was not overcrowded. Certainly there are centres where too many doctors are congregated, leading to local congestion of medical service and the evils of undue competition, but against these centres there may be set off rural districts where the inhabitants are far from thinking that they are too well supplied with doctors, and where shortage has led to an apprehension of the abuses of monopoly. Until recently those who averred that the profession was overcrowded had few facts behind them; but to-day the position is altered.

It must be regarded as a high tribute to our calling that the desire to enter it has become of late so much keener among young men and young women, finding support also among those who have to take thought for the future of their children and charges. There is no one cause for this attitude either among the juniors or the seniors; many things have played their part to bring it about. The events of the war count first, for our science and art emerged from that protracted and terrible struggle with steadily increasing credit. In medicine and in surgery discoveries were made of fundamental importance, while along all lines old techniques were tried, modified, improved, or rejected; and side by side with the advances in scientific equipment there was manifested by medical officers, in all the Services and under all the conditions of employment, a spirit of zeal and devotion which brought medicine before the public eye in a deservedly favourable way. These things have proved great inducements to enter the medical career, but already, and before the war had exercised any influence, the wishes of much of our youth were set in that direction. Added opportunities now make the ambition to become a doctor more easily realisable. The rise of provincial universities has led to a high standard of professional education all over the kingdom, and has brought entry into the profession—and entry amidst favourable circumstances unknown to the last generation—within the grasp of literally thousands of aspirants. Nor is the career any longer the pecuniary adventure that it was for so many who, in the last two generations, struggled into our ranks, often to have those struggles rewarded by a life of perpetual poverty, and sometimes by undoubted leadership among us. The National Insurance Act, that enormously criticised measure, has undoubtedly stabilised general practice in many directions. Obviously it has done away with the need to possess any large capital sum of money before embarking upon private practice; a certain livelihood can be made from the outset, and we refuse to believe that the conditions of that livelihood will not soon be much improved from the view-point of both medicine and the public. We are only as yet at the beginning of a domestic revolution, having for its object the maintenance of the health of the people; and when fuller coöperation between medicine and the public arrives, and when the doctrines of prevention in its larger sense have been learned, the life of the general practitioner, though ordered on a new pattern, will be seen in its proper place as the finest life which can be lived by those who would serve humanity. The institution of the Ministry of Health has familiarised the public with the aims of medical endeavour and the directions of medical thought; so that wise parents turn to our calling as a great future for their children.

Such are the factors which have been acting with greater or less force to bring about a steady increase in our students' ranks, and now we may fairly expect an addition to the roll of qualified medical men in the year 1925 of some 3000 practitioners, and of some 2000 more in each of the years immediately following. And we hesitate to say that even with these figures the medical profession will be overcrowded, for there is more work to do now than there ever has been, and more hearts, heads, and hands are required for its performance. The four great Services offer splendid chances of medical work and material success. Every development of medicine shows us that our profession can enter into relations with provinces of life from which it has hitherto seemed to be entirely detached—we have only to look at the multiplicity of medical questions which now come under consideration in both Houses of Parliament, and receive in each House marked attention, to be sure of this. With this expansion of work to do an increase in the number of those who have to do it will be necessary. At the same time prudence dictates the taking of measures to prevent too many people from seeking the same employment, thus lowering the conditions of that employment, and losing the public advantage that may now be derived from recruiting for medical work a fine section of young people. What does economy say? At first sight it does not seem to be a move towards economy to suggest that many more doctors are required than the community has hitherto felt the need of, while they must be better paid than their predecessors. But that is not the right way to state the situation. What really has come about is that an appreciation of the many sides of life with which medicine, especially in its preventive aspects, is concerned, has grown up. The necessity of medical counsel of a trustworthy character is being felt in new places, while it is perceived that money spent in securing adequate medical service is saved, and saved again, in man-power.

same concessions, if any, as may be granted to other officers in civil employ.

The rates of basic pay and pensions are given below:—

NEW RATES OF PAY.

(Given in rupees per mensem.)

Rank.	Year of service.	Basic pay.	Overseas allowance.	Total basic pay and overseas allowance.	Rank.	Year of service.	Basic pay.	Overseas allowance.	Total basic pay and overseas allowance.

S.L.—Selected List.

Charge allowances and second-in-command allowances for station hospitals will be admissible in addition to the above rates of pay at the following rates:—

(a) *Charge Allowance.*

	Rs. per mensem.
1st class hospitals ..	240
2nd class hospitals ..	180
3rd class hospitals ..	120
4th and 5th class hospitals	nil.

(b) *Second-in-Command Allowance.*

	Rs. per mensem.
1st class hospitals ..	120
2nd class hospitals ..	90

All existing general allowances paid to holders of professional and bacteriological appointments and certain other special classes of appointments on the civil side will be maintained.

Indian officers who have joined or may join the service after Dec. 1st, 1918, will draw, as from Jan. 1st, 1920, pay in accordance with the basic scale, unless they are already drawing pay at a higher rate, in which case they will continue to enjoy the benefit of that rate for so long as they would otherwise have done; but they will not receive any further increment until it is due to them under the basic scale.

PENSIONS.

The pension rates as now revised give £400 a year after 17 years' service, increasing to £800 after 27 years' service. Formerly the rate was £300 after 17 years' service, increasing to £700 after 30 years' service.

Pension Rates.

After 17 years' service ..	£400	After 23 years' service ..	£620
" 18 " ..	430	" 24 " ..	660
" 19 " ..	460	" 25 " ..	700
" 20 " ..	500	" 26 " ..	750
" 21 " ..	540	" 27 " ..	800
" 22 " ..	580		

Additional pensions for administrative officers:—

Colonel, after two years' active service as such	£125
After four years	250
Major-General, after one and a half years' active service as such	300
After three years	350

It is quite impossible to foretell how and to what extent the civil side of the I.M.S. will be affected by the Indian Reform scheme, the essence of which is the increasing participation of Indians in the government of the country. None the less, we consider it right to draw the attention of young medical men who are considering joining the Indian Medical Service to this aspect. At the same time we see no reason why the increased coöperation of Indian and European medical officers should not, if a sympathetic attitude is adopted, result in the benefit of both. The number of Indians in the I.M.S. in the days of the competitive examination varied from 8 to 12 per cent. In the two or three years before the war the percentage of successful Indian candidates varied from 12 to 30 per cent. At the present time European and Indian candidates are admitted by nomination in the proportion of 2 Europeans to 1 Indian. A strict system of selection is maintained and permanent commissions are only granted to candidates, whether Europeans or Indians, who have been recommended after a personal interview as suitable and desirable professionally and socially. Practically all the Indian candidates recommended so far have served in the field with distinction and have been recommended by two of their brother officers for the grant of a permanent commission.

A Board of Selection has been appointed in India for the recruitment of permanent officers for the I.M.S. in the manner indicated, consisting of the Director-General, I.M.S., the Director of Medical Services in India, and an Indian Officer, I.M.S. Candidates who may be summoned by the Board for interview will, if considered suitable for appointment, be placed in one of two classes, according as they have or have not received their medical education chiefly in England. The final recommendations as to the former will be made by the Selection Board in England, while the recommendations as to the latter will be sent direct from India to the Secretary of State, who will make appointments to fill the vacancies. The Selection Committee in England, in addition to considering applications from India of candidates who have mainly received their education in England, will review those of the candidates in the United Kingdom, but not the recommendations of the India Committee in regard to candidates educated in that country.

For full particulars intending candidates should apply to the Secretary, Military Department, India Office, Whitehall, London, S.W. 1.

WOMEN'S MEDICAL SERVICE FOR INDIA.

THIS service is open to properly qualified medical women of British or Indian nationality who desire to carry on work in India. The service was founded in 1913 by the Countess of Dufferin's Fund, the committee of which was granted an annual subsidy of 1½ lakhs (£10,000) by the Government of India for this purpose. The salaries first offered have lately been found inadequate, partly owing to the rapid rise of prices due to the war. Proposals for a substantial increase of pay have now been accepted by the Government of India.

Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. During this period (from six months to two years) private practice is not allowed. For a further period they are appointed to act temporarily for medical women on furlough, during which time private practice is allowed. They are then definitely appointed to the charge of hospitals. Private practice is always allowed after the first two years, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1000 a year.

Excellent opportunities for surgery—especially gynæcological—are found in the Women's Medical Service. The prevalence of osteomalacia in some parts of the country leads to the necessity for frequent Cæsarean section, while uterine fibroids, ovarian tumours, and diseased tubes swell the number of abdominal operations. The number of large operations performed will vary with the surgical reputation of the medical woman, but in some cases it is considerable.

in lieu of rations when not victualled in kind, while arrangements are made for officers in temporary employment on shore. No unemployed or half pay is granted, but there are pensions for wounds or injury on duty, and in the event of death the officer's widow and children would fall under regulations applying to officers on the permanent list. There is an equipment allowance for ordinary uniform of £50, but the officer provides himself with a pocket case of instruments and a stethoscope.

A short service surgeon lieutenant after six months' service, on application to the Secretary of the Admiralty, may be considered for transfer to the permanent service on a satisfactory report being received from the senior medical officer of the Squadron Hospital or Depot in which he has served or is serving as to his professional ability, and a favourable report from his commanding officer as to conduct. Such candidates must have been under the age of 28 on joining for short service, and officers so transferred will not be eligible for the gratuities provided. They will be permitted to count their seniority from date of entry for short service for purposes of promotion and for increment of full pay, and similarly they will be permitted to count their service from the date of entry for purposes of retired pay, but for purposes of retiring gratuity on the permanent officers' scale their services will be reckoned only from the date of transfer to the permanent list, this date being that of receipt in the ship or establishment in which the officer is serving of the order for his transfer to the permanent list. Until that date he will retain his temporary rate of pay.

If a short-service lieutenant wishes to transfer to the permanent service he will then come under the following conditions of pay and pensions :—

RATES OF PAY AND PENSION.

—	Year of 365 days.			One day.		
	£	s.	d.	£	s.	d.
Surgeon Rear-Admiral ..	1916	5	0	5	5	0
Surgeon-Captain :						
On promotion	1186	5	0	3	5	0

On promotion	638	15	0	1	15	0
After 3 years' seniority	675	5	0	1	17	0
Surgeon-Lieutenant :						
On entry	438	0	0	1	4	0
After 3 years' seniority ..	529	5	0	1	9	0

On first appointment to the Service, Medical Officers will receive full pay from date of appointment, but subject to the provisions of Article 1347 of the King's Regulations, 1913.

Flag Allowances.

An allowance of 5s. 0d. a day in addition to full pay is granted to the Senior Medical Officer of a flagship bearing the flag of a Commander-in-Chief. An allowance of 2s. 0d. a day is granted to the Senior Medical Officer of a ship bearing other flags or broad pendants.

Rates of Pension.

Compulsory retirement will be as follows :—

(i) Surgeon Rear-Admirals retire at the age of 60 with retired pay at the rate of £900 per annum plus £22 per annum for each year's service over 27 years counting for retired pay, subject to a maximum rate of £1010 per annum. If, however, less than 27 years' service counting towards retired pay is rendered, a deduction of £22 per annum is made for each full year wanting to complete that period, subject to a minimum of £700 per annum.

(ii) Surgeon-Captains retire at the age of 55. Maximum retired pay, £900.

(iii) Surgeon-Commanders retire at the age of 50. Maximum retired pay, £600.

(iv) Surgeon Lieutenant-Commanders and Lieutenants retire at the age of 45. Maximum retired pay, £450.

Subject to these maxima, the rates of retired pay for Surgeon-Captains, Surgeon-Commanders, Surgeon Lieutenant-Commanders, and Surgeon-Lieutenants are as follows :—

Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)		Age on retirement.	Retired pay.	Period of service (years) counting towards retired pay.	(A)	
			Addition.	Deduction.				Addition.	Deduction.
	£ (p.a.)		£ (p.a.)	£ (p.a.)		£ (p.a.)		£ (p.a.)	£ (p.a.)
55	790	24	22	15	47	562	20	15	15
54	765	24	22	15	46	525	20	15	15

48	600	21	15	15	40	300	17	15	15

(p.a.) = per annum.

(A) Addition for each full year's service in excess of that specified in column 3 or deduction for each full year wanting to complete that period of service—addition or deduction limited to five years in each case.

ARMY MEDICAL SERVICE.

THE recent alterations in the conditions of service in the Royal Army Medical Corps, which constituted, as we said at the time, the greatest reform that has taken place in that Service for a generation, have well fulfilled their promise. For many reasons which are obvious and have been detailed on previous occasions, the Service can be thoroughly recommended to young medical practitioners. The Regulations should be obtained from the Army Medical Department, and carefully studied.

These are the things which the man who contemplates joining the Service should bear in mind. The rates of pay and allowances are good; the chances of seeing the world and the opportunities for post-graduate study are generous, and the work is nowadays varied, responsible, and interesting. At certain periods the young officer is relieved from all other duties for six months for the purpose of post-graduate study. During this period he is on full pay and the fees for his courses of instruction are paid by the State. His time is devoted to post-graduate work, and the leading clinical and scientific institutions are coöperating to secure that this post-graduate work shall be real and fruitful. Officers who show a marked aptitude for special subjects and have had previous practical experience in them are now selected to undergo a specialist course lasting for a further six months, thus giving these officers a post-graduate course of 12 months in place of the maximum of nine months that previously obtained. This is already resulting in better trained and more highly skilled specialist officers being turned out by the Royal Army Medical College. At the same time in districts where the privilege would be of the most practical value opportunities are forthcoming for young officers to attend the clinical practice of large local general hospitals.

By a Royal Warrant issued in September, 1919, medical and combatant officers were placed on the same footing as regards retired pay, and the fact that medical officers enter the Service after a long and expensive training some five years later in life than combatant officers was overlooked. This inequality of treatment has now been rectified, with the result that a medical officer of 20 years' service or over gets £75 per annum more pension than a combatant officer with the same number of years' service.

Once again let us deal with the most frequently repeated criticism of the Service—namely, that administration eternally takes the *pas* of science. The Directorates in Pathology and Hygiene which were recently created in the R.A.M.C., and which

An outfit allowance of £30 will be granted to officers if they have had no previous commissioned service. If they have had previous commissioned service in the Royal Navy, the Army, or the Royal Marines, but not in the Royal Air Force, they will receive an outfit allowance of £25.

Officers on entry are required to provide themselves with the regulation pocket case of instruments.

RATES OF PAY AND RETIRED PAY.

42	18	375	15	15
41	17	337	15	15
40	17	300	15	15

* Limited to five years.

Group Captains retire at 55; maximum retired pay £900.
Wing Commanders retire at 51; maximum retired pay £600.
Squadron Leaders retire at 48; maximum retired pay £500.

There will be a minimum qualifying period for retired pay of 20 years.

Gratuities.

Short-service officers will receive gratuities at the rate of £100 for each of the first two completed years of service, and at the rate of £150 for the third and fourth completed year. (If granted permanent commissions these gratuities will not be payable, but the period of service under the short-service commission will count for retired pay.)

Medical officers holding permanent commissions may, at the discretion of the Air Council, be allowed to withdraw from the Service after ten years' service with a gratuity of £1250 or after 16 years with a gratuity of £2000 in lieu of retired pay.

Allowances.

The usual allowances will be payable to medical officers under the same conditions as to officers of other branches of the Royal Air Force.

COLONIAL MEDICAL SERVICE.

IN the self-governing dominions, Canada, Australia, New Zealand, the Union of South Africa, and Newfoundland, medical appointments are made concerning which information can be obtained from the High Commissioners or Agents-General in London; appointments in Egypt and the Soudan are regulated from the Foreign Office; in Rhodesia the appointments are made by the British South Africa Company, London Wall Buildings, E.C.; in North Borneo application should be made to the British North Borneo Company, 37, Threadneedle-street, E.C., for appointments; and those in Sarawak are in the hands of H.H. the Rajah.

But in addition to all these there are a large number of important posts under the patronage of the Secretary of State for the Colonies. These concern East Africa (the East Africa, Uganda, Nyasaland, Somaliland and Zanzibar Protectorates); the Far East (Ceylon, the Straits Settlements, and Federated Malay States, Hong-Kong, Weihaiwei, Mauritius, and Seychelles); West India (British Guiana, Jamaica, Trinidad, the Windward Islands, the Leeward Islands, Barbados, British Honduras, and the Bahamas); Fiji and the Western Pacific, Cyprus, Malta, Gibraltar, St. Helena, Bermuda, and the Falkland Islands; and West Africa (Nigeria, the Gold Coast, Sierra Leone, and the Gambia). As a general rule, each Colony or Protectorate has its own public service distinct from that of every other, and it is usually only the higher officers who are transferred by the Secretary of State from one Colony to another; but there are two exceptions to this rule. The West African Medical Staff, which serves Nigeria, the Gold Coast, Sierra Leone, and the Gambia, form one service, and in practice the medical services of the Straits Settlements and the Federated Malay States may be regarded as one, as the officers may be and frequently are transferred from the Colony to the States, or vice versa. In Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, and Bermuda vacancies are almost always filled locally by the appointment of qualified native candidates, or—in the case of some of the higher posts—by transfer from other Colonies. Appointments in Malta are all filled locally. Vacancies in the Hong-Kong Medical Department are generally filled by transfer from other Colonies. Medical appointments in the Bechuanaland Protectorate, Basutoland, and Swaziland are made only on the recommendation of the High Commissioner for South Africa, who usually appoints local candidates. In most cases the duties of a colonial medical officer are of a very general character, including medical, surgical and often public health work. It is only occasionally that a specialist is required.

Applicants must be between the ages of 23 and 35 and doubly qualified, and the choice will usually fall on those who have held hospital appointments. Before being definitely appointed candidates will be medically examined by one of the consulting physicians of the Colonial Office: Sir J. Rose Bradford, K.C.M.G., 8, Manchester-square, London, W.; Sir J. Hawtrey Benson, 57, Fitzwilliam-square, Dublin; Lieutenant-Colonel J. Arnott, I.M.S., 8, Rothesay-place, Edinburgh; and W. T. Prout, Esq., C.M.G., 14, Rodney-street, Liverpool.

East Africa.—There are now vacancies for Medical Officers and Medical Officers of Health in East Africa. It is usual to select Medical Officers of Health from among officers already serving as Medical Officers, and in the wording of the regulations the term "Medical Officers" covers "Medical Officers of Health," save where the context indicates otherwise. Medical Officers selected for appointment to East Africa are allocated to one of the following administrations: Kenya Colony and Protectorate, Nyasaland Protectorate, Somaliland Protectorate, Tanganyika Territory (late German East Africa), Uganda Protectorate, Zanzibar Protectorate. Whenever possible, a successful candidate is allocated to the Administration for which he expresses a preference. The conditions of service are here summarised: Appointments held by Medical Officers are on the permanent and pension-element for the rank from which the officer retires. An officer with less than 20 complete years' service will not be eligible for retired pay.

2. The scale will be as follows:—

(*a*) Service element.—£15 a year for each completed year of service.

(*b*) *Rank element.*—

Rank from which retired.	After completing 1 year's service in the rank.	After completing each additional year's service.	Maximum rank element.
	£	£	£
Major	12	12	120
Lieutenant-Colonel	150	30	240
Colonel	290	50	390
Major-General ..	410	50	540
Lieutenant-General	590	50	690
General	740	50	840

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

Maximum rates of retired pay (*a*) and (*b*) together:—

	£		£
Captain and Subaltern ..	300	Colonel	800
Major	450	Major-General ..	1000
Lieutenant-Colonel ..	600	Lieutenant-General	1200

Officers with 8½ and less than 20 years' service may be permitted to retire with a gratuity varying from £1000 to £2500.

Lastly, we may remark that arrangements are now being made to appoint Consultants in both Medicine and Surgery and the ranks of Colonel and Major-General will now be open to such Officers. The duties of these Officers are to visit all Commands and advise the Director-General, as the result of their inspections on the spot, with regard to the professional work being carried on in the hospitals, and the degree of efficiency attained by the personnel with whom they are respectively concerned. This should ensure a high standard of performance if only because of the satisfactory feeling that good work will not by accident remain unnoticed.

The present holder of the post of Consultant in Surgery is Colonel E. M. Pilcher, recently Professor of Surgery at the Royal Army Medical College. No officer has yet been appointed as Consultant in Medicine.

INDIAN MEDICAL SERVICE.

THE Indian Medical Service differs from all the other State Services in that it combines the attractions of a military and a civil career. It is primarily a military service, and all officers on first landing in India are detailed for service with Indian troops in Indian military station hospitals. After a period of military duty, which before the war varied from four to eight years, the majority of officers chose and were transferred to the civil side. While in civil employ they constitute the war reserve for the Indian Army. During the great war practically all officers not occupying administrative posts or filling essential civil duties were called up for military service.

The possibilities of medical and surgical work and the opportunities for research in all directions which the Service affords have always proved of great attraction, though in recent years the Service has lost its former popularity in the medical schools, and for some time prior to the war competition among highly qualified European candidates was not keen. Under the changed conditions in India the pay and emoluments were insufficient, and the terms of service were out of date. The whole constitution and organisation of the Service has recently been under examination by a Medical Services Committee. The report of this Committee has not yet been published, but it is understood that its recommendations are such as seem likely to restore the Indian Medical Service to its former high position and prestige among the State Services. Meanwhile, the pay, pensions, and leave reserve have been substantially increased, whilst questions relating to furlough pay, passages, status of administrative officers are in process of satisfactory settlement. The Station Hospital system has been introduced and command allowances and second in command allowances have been granted for charge of hospitals. These reforms, now happily ensured, have completely altered the outlook. Young medical practitioners can now join the I.M.S., being secure of a competency from the day they receive their commissions. A great career is open to one with the proper qualities and keenness.

During the first few years the young officer is trained in Indian military medical organisation. He acquires experience in dealing with the different races and castes which comprise the Indian Army. He learns the language and customs of the country. He familiarises himself with the practice of tropical medicine and surgery, and has leisure to pursue his further studies with time for recreation and sport in any direction his inclination may dictate. During these years he can make up his mind as to any special branch of study, and whether he is desirous of remaining in military employ throughout his service. Specialist appointments are available on both the military and civil sides.

On the civil side, and the majority of officers are civil surgeons in charge of districts and the civil district hospitals, the work is heavy and interesting, the bulk of it being surgery. There is no country in the world which offers better opportunity for the young surgeon once he has acquired the confidence and esteem of the inhabitants. Private practice is permitted, but it may be stated at once that the emoluments from this source, except in the Presidency or large towns, are generally negligible. Nevertheless, with the pay as it now exists, plus certain minor allowances, the civil surgeon is in a position to live reasonably in his earlier years, and can expect to be selected for the higher professional posts as a reward of merit, when a lucrative practice may be obtained. I.M.S. officers are eligible for the professorships at the Medical Colleges in Calcutta, Bombay, Madras, Lahore, and Lucknow in the various subjects comprising the medical curriculum. The bacteriological, sanitary and chemical examinerships, and the work asylums and jail departments open out careers of a varied and valuable kind for those who wish to devote themselves to scientific research or specialist work. The bacteriological laboratories and Pasteur institutes at Kasauli, Bombay, Conoor, Shillong, and Rangoon are splendidly equipped with provision for research workers. In addition to the scales of pay laid down, allowances are granted for service in these different directions.

Under the study leave rules officers are entitled during their service to a year's study leave in England. This period counts as duty, and is in addition to furlough. It is granted on the basis of one month's study leave for each year's active service up to a total maximum of 12 months. Most officers take it in two periods of 6 months each, and add it on to their ordinary furlough. During the period of study leave they are at liberty to pursue courses of approved study in any country. They receive furlough pay plus an additional lodging allowance of 12s. a day. The opportunity thus provided for continuing post-graduate studies for a period of six months twice in his service is invaluable both to the individual and the State.

Accelerated promotion of six months to the rank of major is granted to officers for approved study or for obtaining the higher medical qualifications.

As regards leave, the Secretary of State has undertaken to increase the leave reserve to 25 per cent. and maintain a 2½ per cent. study leave reserve in addition. These percentages when worked up to are considered ample.

The Secretary of State has further undertaken that officers of the I.M.S. on the military side will receive the same concessions as regards passages as combatant officers, while officers on the civil side will receive the are pensionable. There are at present 18 Medical Officers, three of whom are also Magistrates, in addition to a Chief Medical Officer (£700 a year, rising to £800), a Medical Officer of Health (£500, rising to £600), and a Senior Medical Officer (£450–£500). The medical services of Fiji and the Western Pacific are interchangeable. While serving in the Western Pacific Protectorates their duties may be of a quasi-magisterial nature, and they draw an extra non-pensionable allowance of £50 per annum.

Cyprus.—There is a Chief Medical Officer paid at the rate of £750 to £900 per annum, and three District Medical Officers paid at the rate of £500 to £600 per annum, all enjoying private practice (except the Chief Medical Officer, who is allowed consulting practice only) and receiving 2*s.* per diem forage allowance; these are the only medical appointments in the island which are open to English candidates.

Gibraltar.—There is a surgeon of the Colonial Hospital receiving £750 with fuel and light allowances, and private practice. He also receives £50 for medical examination of school children. There are also two Assistant Surgeons with a salary of £720 per annum, who are allowed private consulting practice only. Free quarters, unfurnished, are provided for all three officers.

St. Helena.—The Colonial Surgeon at present receives £300 per annum, £20 fees as Health Officer, and £30 horse allowance. Private practice is allowed. The Assistant Colonial Surgeon receives £550 a year and a horse, with forage allowance; but no private practice is allowed without special permission.

Falkland Islands.—There are two appointments. The Colonial Surgeon is paid at the rate of £600 per annum, with £25 as Health Officer. The Assistant Colonial Surgeon is paid at the rate of £500 per annum without quarters. Part of the salary is provided from private sources. Private practice is allowed to the Colonial Surgeon, and to a lesser extent to the Assistant Colonial Surgeon.

Leave and Passages.—In the East African Protectorates leave of absence on full salary is granted in the normal case after a tour of residential service (of not less than 20 nor more than 30 months) to an amount of five days for each completed month of residence (or 2½ days when for any reason the officer is not returning to East Africa) exclusive of the periods of the voyages to and fro. Officers serving in Uganda, Zanzibar, or in certain stations in the East Africa and Nyasaland Protectorates are allowed six or three days' leave respectively in respect of each month of service. In Somaliland special leave regulations exist which provide for an officer taking leave approximately every year. Free first-class passages are provided for the officer only. In the Malay Peninsula two months' leave of absence with full salary may be granted in respect of each year's service, and this leave may be accumulated up to a maximum of eight months. Additional leave on half pay may be granted on special grounds. If an officer on the occasion of his first leave is in receipt of a pensionable salary of less than £500 a year, he is granted a free return passage to the United Kingdom. In Hong-Kong leave of absence on half salary may be granted after 4½ years' service, and a portion of such leave may be commuted, if the Governor agrees, for half the amount on full pay. Leave of absence in excess of 10 months at a time will not be granted, but an extension may be allowed for ill-health or very urgent private affairs.

Subject to the necessities of the service, leave of absence on half salary may be granted to officers in other Colonies outside tropical Africa after a period of six years' resident service without any special grounds. Officers of the Fiji and Western Pacific service proposing to spend their leave in Europe may receive a grant in aid of passage expenses of £60. Leave may be given before the expiration of the due period in case of serious indisposition, or of urgent private affairs. In the absence of special grounds, the leave must not exceed one-sixth of the officer's resident service; on special grounds it may exceed that period by six months. In addition to the above, vacation leave on full pay may be granted, if no inconvenience or expense is caused thereby, not exceeding three months in any two years. In the case of Fiji and the Western Pacific and the Falkland Islands, 4½ months' leave may be granted in any three years.

On first appointment an officer whose salary and fees together do not exceed £700 a year will, except in the case of a few Colonies possessing Representative Assemblies, be provided by the Crown Agents for the Colonies with free passages to the Colony for himself and his wife and children, if any, not exceeding four persons besides himself. The officer so appointed will be required to execute an agreement binding him to repay the cost of the passage or passages so obtained in the event of his leaving the Government service within three years. This rule applies also to officers appointed to the Malay Peninsula and Hong-Kong. An officer taking leave out of the Colony has to provide his own passages.

Pensions.—Officers on the pensionable establishment in the East African Protectorates are at liberty to retire on attaining the age of 50 years. Earlier retirement in the event of ill-health is also provided for. Pensions are computed on the scale of one-sixtieth of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement, but for purposes of calculating pensions two years' service is reckoned as service for three years. In most of the other Colonies an officer holding a pensionable appointment may be allowed in the case of ill-health to retire on a pension after ten full years' resident service; otherwise he must have attained the age of 55. For ten full years' resident service fifteen-sixtieths of the average annual salary of the retiring officer's fixed appointments for three years prior to retirement may be awarded, to which one-sixtieth may be added for each additional year's service; but no addition will be made in respect of any service beyond 35 years. For pension purposes absence on vacation leave counts as full service, and leave on half pay as half service. In a few cases the retiring age is 60, and the pension after ten years' service is ten-sixtieths instead of fifteen.

Applications should be made in writing to the Assistant Private Secretary (Appointments), Colonial Office, Downing-street, London, S.W. 1.

West African Medical Staff.

The medical services of the West African Colonies and Protectorates—namely, the Gambia, Sierra Leone, the Gold Coast (including Ashanti and the Northern Territories), and Nigeria—form one service under the above name. All the medical officers for the service are selected by the Secretary of State for the Colonies, and are on one list for employment and promotion. As in other Colonies, applicants must be between 23 and 35 years of age and possess a double qualification, but preference is given to those over 25. The higher grades are usually filled by promotion from the lower. Camp outfit must be taken out by every medical officer, and an allowance of £30 is given towards its purchase on appointment.

The grades and emoluments of officers of the staff are as follows:—

The Director of the Medical and Sanitary Service in Nigeria receives a salary of £1700 a year, with a duty allowance at the rate of £340 a year.

Principal Medical Officer: The Principal Medical Officers receive salaries as follows: In the Gold Coast and the Southern Provinces of Nigeria £1500 a year, with a duty allowance at the rate of £300 a year. In Nigeria (Northern Provinces), £1500 a year, with a duty allowance at the rate of £300 a year. In Sierra Leone, £1350 a year, with a duty allowance at the rate of £270 a year. There is no Principal Medical Officer in the Gambia.

Deputy Principal Medical Officer: There are four appointments of this grade, two in the Southern Provinces of Nigeria and one each in the Northern Provinces and in the Gold Coast respectively. Salary at the rate of £1300 a year is attached to these appointments, together with a duty allowance at the rate of £260 a year.

Senior Sanitary Officer: There are four appointments of this grade, two in Nigeria, one in the Gold Coast, and one in Sierra Leone. Salary at the rate of £1300 a year is attached to these appointments, together with a duty allowance at the rate of £260 a year.

Provincial Medical Officer: There are seven appointments bearing this title (four in Nigeria, two in the Gold Coast, and one in Sierra Leone), with salary at the rate of £1200 a year, and duty allowance at the rate of £240 a year.

Senior Medical Officer: There are 20 appointments of this grade, with salary at the rate of £1000 a year, rising by annual increments of £50 to £1150 a year, and proficiency pay of £100 a year. The Senior Medical Officer of the Gambia draws staff pay at the rate of £120 a year, in addition to duty pay, but is not allowed private practice.

Sanitary Officer: There are seven appointments of this grade, with salary at the rate of £1050 a year, rising by annual increments of £50 to £1200 a year, and a duty allowance at the rate of £210 a year.

Medical Officer: The salary is at the rate of £660 a year, rising by annual increments of £30 to £720; and then by £40 to £960, with proficiency pay of £72 a year. Before passing £800 Medical Officers are required to take a special course of study for three months; if satisfactory they then continue to draw increments up to £960. A Medical Officer who has served for three years on the maximum of this scale (£960) is eligible to be placed on the same scale of salary as a Senior Medical Officer.

Special appointments: The Director of the Medical Research Institute, Lagos, and the Pathologist, Accra, receive a salary of £1300 a year, with a duty allowance of £260 a year. Salary at the rate of £800, rising by annual increments of £40 to £960 a year, with a proficiency pay of £72 a year, is attached to about ten posts (those of

To those who are not keen surgeons opportunities are likely to open in the future in connexion with maternity and child welfare. The high infant mortality and the suffering of women in childbirth, owing to the ignorance of the untrained hereditary midwives, provide a great field for such workers. Medical women with administrative ability are also needed for the inspection of women's hospitals and other medical institutions.

Rates of pay are as follows:—

Years of Service.	Salary per mensem.	English equivalent* per annum.
1 to 3	Rs.450	£360
4 to 6	Rs.500	£400
7 to 9	Rs.550	£440
10 to 12	Rs.600	£480
13 to 15	Rs.650	£520
16 to 18	Rs.700	£560
19 to 21	Rs.750	£600
22 to 21	Rs.800	£640
over 24	Rs.850	£680

*At rupee value 1*s.* 4*d.*

The above rates of pay are not so high as those of the Indian Medical Service. The fact, however, that furnished quarters are provided (these are not provided in the Indian Medical Service) represents an additional Rs.150 per mensem. It must be remembered, too, that the official duties of the members of the W.M.S. are lighter than those of the I.M.S., who while in civil employ, in addition to work in the civil hospitals have charge of the medico-legal work of the district, give much gratuitous attendance, and form a reserve to be drawn on in time of war.

The cost of living in India is much higher than formerly, but even now it is possible to live more cheaply than in England for the same measure of comfort. The cost of all goods brought from Europe is very high, but the cost of country produce is much less than in Europe. Meat, poultry, milk, eggs, &c., are sold at about half the price now demanded in England. It should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs.200 per mensem, leaving the remainder of her salary for dress and personel expenses. To this must be added the necessary saving to meet additional expense for furlough and leave spent in the hills.

One month's privilege leave on full pay is granted each year. Furlough on half-pay at the rate of two months for every year of service is granted after every three years. Study-leave on two-thirds pay is granted to the extent of 12 months in the total service. There is a provident fund to which members of the service contribute 10 per cent. of their pay. The service contributes another 10 per cent. which accumulates at interest and is repaid on retirement.

Admission to the service is made by selection. Candidates in the United Kingdom should apply to the Hon. Secretary, United Kingdom Branch of the Countess of Dufferin's Fund, care of Sir Havelock Charles, India Office, Whitehall, London.

AIR FORCE MEDICAL SERVICE.

THE Royal Air Force Medical Service offers a career for medical men which should prove both attractive and interesting. The rates of pay and allowances are good, and a new field of scientific interest is opened up by the manifold problems which the circumstances of aviation produce. The physical and mental fitness for, and reaction to, the varied conditions under which the flying personnel perform their functions provide much scope for research. As promotion to the higher ranks of the Service is to be entirely by selection, and as a certain proportion of the higher ranks will be reserved for purely scientific, as opposed to administrative, appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits ability and energy in scientific research, as well as for those who develop a talent for administration.

The establishment will consist partly of permanent and partly of short-service officers. Short-service officers will be admitted by direct entry for a period of two years, which may be extended to four years at the discretion of the Air Council on recommendation of the Director of Medical Services. Those who are not selected for permanent commissions will pass into the Royal Air Force Medical Reserve at the expiration of their period of service on the active list, and will then receive the gratuity to which their service entitles them.

Short-service officers who are approved for permanent commissions, but for whom there are not vacancies in the Royal Air Force Medical Service, may, under certain conditions, transfer to the Royal Army Medical Corps, counting their time served in the Royal Air Force towards increments of pay and retired pay in the Royal Army Medical Corps.

Officers who have been selected for permanent commissions will be granted leave for a period not exceeding nine months for post-graduate study in general medicine and surgery, tropical and preventive medicine, and other special subjects. Such leave will be granted during the first six years of permanent service, and during such leave officers will remain on full pay and allowances.

New entrants into the Royal Air Force Medical Service will be commissioned as Flying Officers (Medical) and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will be promoted to the rank of Squadron Leader after 10 years' total service. Accelerated promotion may be carried out, in a limited number of cases, of officers who show exceptional ability after the completion of eight years' service. Promotion to the rank of Wing Commander will be by selection at any period after 16 years' total service, and to that of Group Captain by selection at any period after 22 years' service.

There will be no competitive examination on entry; candidates must be under 28 years of age, be nominated by the Dean of a recognised medical school or teaching hospital, and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce—

1. Birth certificate.
2. Medical registration certificate.
3. A declaration containing the following information:—

(*a*) Age and place of birth.

(*b*) That he is of pure European descent, and the son of a subject of the British Empire.

(*c*) That he labours under no constitutional or mental disease or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate in peace or war. (All candidates will be required to pass a medical examination as to their physical fitness before acceptance to ensure that they fulfil the standard laid down in this declaration.)

(*d*) That he is ready to engage for general service at home or abroad as required.

(*e*) The qualifications he is possessed of, and what medical or other appointments he has held (if any).

(*f*) That he is willing to fly whenever called upon to do so, and to qualify in such aviation tests as may be required.

If the applicant is in possession of a certificate of training in an Officers' Training Corps this should be submitted.

An applicant who at the time of application holds, or is about to hold, a resident appointment in a recognised civil hospital may be seconded for the period not exceeding one year, during which he holds such appointment. Whilst seconded he will not receive pay from Air Council funds, but his seniority will count from the day on which he is seconded to the civil hospital.

Uniform and Equipment.

Medical officers will be required to provide themselves with the uniform of their rank and with the distinguishing badges of the Royal Air Force Medical Service. They will be required to provide themselves with service dress and mess dress. The provision of full dress is entirely optional.

Engineering, Vital Statistics. The examination is in two parts, which may be taken together or separately; but Part I. must be passed either before or at the same examination as Part II. The fee for admission to the examination is £10 for each part. Successful candidates are entitled to receive the Diploma in Public Health.

The First Part of the examination will comprise (*a*) written papers of three hours each in (i.) Chemistry and Physics, and (ii.) Pathology and Bacteriology; (*b*) a three hours' practical and vivâ voce examination in Chemistry and Physics; (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

The Second Part of the Examination will consist of the following parts:—(*a*) Two written papers, each of three hours, dealing with General Hygiene (including Sanitary Engineering, Vital Statistics, and the Laws relating to Public Health); (*b*) a practical and vivâ voce examination in General Hygiene; and (*c*) a three hours' practical and vivâ voce examination in Pathology and Bacteriology.

Candidates in Part I. of the examination will be required to produce certificates (1) of Laboratory Work in Chemistry as applied to Hygiene, and (2) of having had Practical Instruction in Bacteriology, and the Pathology of the Diseases of Animals transmissible to Man.

Candidates in Part II. will produce the following further certificates: (3) of a Practical Knowledge of the Duties, Routine and Special, of Public Health Administration; and (4) of having attended the practice of a Hospital for Infectious Diseases at which opportunities are afforded for the study of the Methods of Administration. All the above degrees are now open to Women Students, and particulars of Scholarships, &c., may be obtained from the Principals of the various Ladies' Colleges. The names of candidates must be sent to the Assistant Registrar of the University, Clarendon Building, Oxford, to whom applications for any further information should be addressed.

University of Cambridge.—Two examinations in so much of State medicine as comprised in the functions of medical officers of health are held during the year. The examination is divided into two parts and demands proficiency in all the branches of study which bear upon the duties of medical officers of health. The examinations in both parts will be oral and practical, as well as in writing. Candidates may present themselves for either part separately or for both together at their option; but the result of the examination in the case of any candidate will not be published until he has satisfied the examiners in both parts. Marks of distinction will be placed against the names of candidates who have specially distinguished themselves in either (1) general principles of hygiene; (2) bacteriology; (3) chemistry in Part I. of the examination; or (4) the second part of the examination, which has reference to State Medicine and to the applications of Pathology and Sanitary Science. Every candidate will be required to pay a fee of £6 6*s.* before admission or readmission to *either part* of the examination, but candidates who have presented themselves before the year 1896 will be readmitted to either part on payment of a fee of £5 5*s.* Candidates must before admission to either part of the examination produce evidence of having satisfied provisions (1), (2), and (3), and before admission to Part II. having satisfied provision (4), above mentioned.

For Part I. of the examination courses of lectures and laboratory instruction are given in the University by Mr. J. E. Purvis on Hygiene, Chemistry, &c., and by Dr. Graham-Smith on Bacteriology. Prof. G. H. F. Nuttall gives a course of lectures on Protozoal Diseases, and on Animal Parasites. For Part II. Dr. A. J. Laird, the Medical Officer of Health for Cambridge, gives courses on Practical Sanitary Administration and in the Administrative Methods of the Infectious Diseases Hospital, and Dr. F. Robinson, the Medical Officer of Health to the Cambridgeshire County Council, on Sanitary Laws, School Hygiene, Epidemiology, Vital Statistics, &c. These courses are open to non-members of the University.

A Diploma in Hygiene is granted to medical graduates whose qualifications are not registrable in England.

All applications for further information respecting examinations and the courses of study should be addressed to Mr. Purvis, Chemical Laboratory, Pembroke-street, Cambridge.

Two Examinations in Tropical Medicine and Hygiene are conducted yearly by the State Medicine Syndicate of the University of Cambridge. The examinations are held in Cambridge early in August and at the end of December. Each examination will extend over four days.

Any person whose name is on the Medical Register is admissible as a candidate to the examination provided (I.) that a period of not less than 12 months has elapsed between his attainment of a registrable qualification and his admission to the examination; (II.) that he produce evidence, satisfactory to the Syndicate, that he has diligently studied Pathology (including parasitology and bacteriology) in relation to Tropical Diseases, Clinical Medicine, and Surgery at a Hospital for Tropical Diseases, and Hygiene and Methods of Sanitation applicable to Tropical Climates. As evidence of study and attainments a candidate may present to the Syndicate (1) any dissertation, memoir, or other record of work carried out by himself on a subject connected with Tropical Medicine or Hygiene; (2) any Certificate or Diploma in Public Health or Sanitary Science he may have obtained from a recognised Examining Body. Such evidence will be considered by the Syndicate in determining whether he is qualified for admission to the examination and by the examiners in determining whether, if admitted, he shall be included in the list of successful candidates.

The examination will be partly in writing, partly oral, and partly practical and clinical (the clinical part will be conducted at a hospital for tropical diseases, at which cases will be submitted for diagnosis and comment), and will have reference to the nature, incidence, prevention, and treatment of the epidemic and other diseases prevalent in tropical countries. Every candidate who passes the examination to the satisfaction of the examiners will receive from the University a diploma testifying to his knowledge and skill in tropical medicine and hygiene.

The fee for the examination is £9 9*s.*, and applications should be addressed to Dr. Graham-Smith, Medical Schools, Cambridge.

University of London.—Candidates for the M.D. degree may offer State medicine as a subject in which to graduate. They must send to the Academic Registrar with their forms of entry certificates (i.) of having, subsequently to having obtained a registrable qualification to practise Medicine, attended a course of practical instruction in a laboratory or laboratories, British or foreign, approved by the University, in which chemistry, bacteriology, and the pathology of the diseases of animals transmissible to man are taught; such course to extend over a period of not less than six months and to consist of at least 240 hours, of which not more than one-half shall be devoted to practical chemistry. (ii.) *Either* of having, subsequently to having obtained a registrable qualification to practise Medicine, during six months (of which at least three months shall be distinct and separate from the above-mentioned period of laboratory instruction) been diligently engaged on not less than 60 working days in acquiring a practical knowledge of the duties, routine and special, of Public Health Administration under the supervision of a person recognised by the University as entitled to grant certificates. *Or* of having held for a period of not less than three years an appointment as Medical Officer of Health of a Sanitary District within the British Dominions, and having a population of not less than able establishment. Medical Officers serve for 3 years on probation, and leave is granted with full pay after every tour of service, the length of a tour being normally 30 months in East Africa. If an officer is not returning for further duty the leave for which he is eligible is the period of the voyage home and 2½ days in England for every month of service; if returning for further duty, the leave for which he is eligible is the period of the voyage home and back to East Africa and 5 days in England for every month of service in East Africa, but at certain stations service qualifies for leave at 3 and 6 days instead of 2½ and 5 days respectively. A free first-class passage is provided by the Government on first appointment and on leave. Quarters (with furniture) are provided free of rent, or if quarters are not available, an allowance is given in lieu. Travelling allowance is paid to officers travelling on duty in East Africa in accordance with local regulations. Private practice is permitted subject to the proviso that it must not interfere with the officer's Government work, but this privilege is not granted to Medical Officers of Health. An Officer is eligible to retire on pension at the age of 50. Pension is calculated on the basis of 1/60th of pensionable emoluments at the date of retirement (i.e., salary and the value of free quarters) for each year of service, 2 years of service being reckoned for this purpose as *three* years. Medical Officers may, however, retire with gratuity, if they wish, instead of waiting to retire at the retiring age on pension. The gratuity is: After 9 years' service, of which not less than 6 years must be resident service in East Africa, £1000; after 12 years' service, of which not less than 8 years must be resident service in East Africa, £1250. Prior to appointment, candidates are required to attend a course of instruction in tropical medicine at the London or Liverpool Schools of Tropical Medicine; if this cannot be arranged, such a course must be taken during the first leave, before a Medical Officer can be confirmed in his appointment. Details of payments made by the Government in respect of these courses are supplied when a candidate has been provisionally selected. The Grades and Salary of the Medical Establishments are as follows:—East Africa Protectorate and Tanganyika Territory and Uganda Protectorate: Principal Medical Officer, £1200; Deputy Principal Medical Officer, £1000; Principal Sanitation Officer, £1000; Senior Medical Officers, Sanitation Officers, £800–£25–£900; Medical Officers and Medical Officers of Health, £600–£25–£900. Nyasaland Protectorate: Principal Medical Officer, £1000; Senior Medical Officer, Sanitation Officer, £800–£25–£900; Medical Officers and Medical Officers of Health, £600–£25–£900. Somaliland Protectorate: Senior Medical Officer, £800–£25–£900; Medical Officers and Medical Officers of Health, £600–£25–£900. Zanzibar Protectorate: Principal Medical Officer, £1000; Sanitation Officer, £700–£25–£800; Medical Officers and Medical Officers of Health, £600–£25–£900. All Medical Officers of Health receive a special non-pensionable allowance of £100 or £50 per annum according to their station in the Protectorates.

Straits Settlements and Federated Malay States.—The services of 33 Medical Officers are required here, the salary offered being $140 a month for the first year, $160 for the second, and $180 for the third year. In all cases the appointments are on probation for the first three years; after which Medical Officers may be placed on the permanent and pensionable establishment. Subject to passing a strict efficiency bar before rising above $600 per month, salaries will thenceforward be at the rate of $500 a month, rising by annual increments of $25 a month to $800 a month. Promotion to posts above this maximum will be by selection. Officers having specialist qualifications of an approved type will enter the scale of salary at $550, rising by $25 a year to $600 per month during the first three years; after which, if their appointments are made permanent and they pass the efficiency test, their salary will rise, as in other cases to $800 a month. No duty allowance is paid. There is at present a strictly temporary increase to meet the increased cost of living; 15 per cent. for unmarried officers; 30 per cent. for married officers. The exchange value of the dollar is fixed by Government at 2*s.* 4*d.* This rate is liable to alteration but has remained constant for the past 11 years, and, so far as can be at present foreseen, no change is anticipated. Candidates must be graduates of one of the British Universities, or hold the qualifications of the College of Surgeons and Physicians of London, Edinburgh, or Ireland, and in some cases a diploma in Public Health. If they have not already done so, they will be required to attend a course of instruction at the London or Liverpool Schools of Tropical Medicine, either before embarkation or during their first leave of absence in Europe. Their whole time will be at the disposal of the Government, and no private practice is allowed. The duties will be generally to take charge of one of the hospitals in the Malay Peninsula, and any other duties on which in the public interest it may be desirable to employ them. Free passages (second class by mail or first class by other vessel) are given, with half salary from date of embarkation. Candidates of over 37 years of age will not be considered for appointment on the above terms. They may, however, be engaged on three years' agreement, renewable by consent of both parties, with salaries commencing at $600 to $700 a month (according to qualifications), and rising annually by $25 a month. Such appointments will not be pensionable and no prospect can be held out of promotion to the highest posts in the Medical Service. A bonus of two months' salary, however, will be payable for each completed year's service on termination of agreement or extended agreement.

Seychelles.—There are four medical appointments. The Assistant Government Medical Officers receive Rs.5000. The holders of these appointments have free quarters. Private practice is allowed.

Weihaiwei.—There are two non-pensionable Medical Officers on salaries £400–£25–£500, with free quarters.

British Guiana.—There are 20 posts at £500–£600, and 8 posts at £600–£700 per annum, and 6 posts at £900. There are several public hospitals and asylums; medical officers attached to these institutions receive plainly furnished bachelor quarters and an allowance in lieu of private practice. There are also many posts as resident surgeons in charge of districts. In these cases a travelling allowance is granted, and in some instances also a free house. A first-class passage to the Colony is provided. Vacation leave of absence on full pay not exceeding three months may be granted by the Governor during and in respect of any two consecutive years' service. Subject to the necessities of the Service, leave of absence on half pay may be granted without any special grounds after six years' resident service from first appointment in the colony, and on special grounds at an earlier date.

Trinidad and Tobago.—In Trinidad and Tobago there are over 40 appointments. Officers are appointed in the first instance on two years' probation as supernumeraries and are eligible for appointment as Government Medical Officers at the end of this period. Applicants must be unmarried and must remain unmarried whilst supernumerary Medical Officers. Supernumeraries receive a salary of £250 per annum with furnished quarters, and are usually attached to the Government hospital. Government Medical Officers receive salary at the rate of £250 per annum with quinquennial increments of £50 accruing from the date of first appointment as supernumerary Medical Officers. Most are employed as District Medical Officers, with private practice, a residence or a rent allowance of £50, a horse allowance, except in one district, and in some cases other allowances for institution work. All officers are required to contribute 4 per cent. of their salaries towards the pensions of the widows and orphans of public officers.

Windward Islands (Grenada, St. Lucia, St. Vincent).—The 25 appointments are, with few exceptions, district appointments with the right to private practice attached; the salaries paid by Government vary from £315–£375, plus bonus, and with allowances in certain cases. The Governor has the power to transfer a medical officer from one island to another at his discretion. The appointments are pensionable.

Leeward Islands (Antigua, St. Christopher and Nevis, Dominica, Montserrat, Virgin Islands).—The 21 appointments are of the same nature as in the Windward Islands, but are not pensionable. An officer when first sent out is not appointed to a particular island but to the service of the Leeward Islands, with a salary of £375 or £400 according to station, and the Governor decides as to the district which is to be allotted to him. He is liable to be transferred to any medical district in the Islands, and in certain districts he may be required to perform magisterial duties. The medical officers receive fees for successful vaccinations, post-mortem examinations, attendance and giving evidence at courts of justice, certificates of lunacy, and, in the larger islands, for burial certificates. They are also, as a rule, allowed private practice.

British Honduras.—There are seven medical appointments (besides the principal post of Colonial Surgeon) each carrying a salary of $1011 to $2430 per annum. Unless they already possess a Diploma of Public Health, medical officers are liable to be required before they join the Colony to undergo a course of instruction at a laboratory of public health or analogous institution. The dollar=about 4*s.* 2*d.*

Fiji and the Western Pacific.—In Fiji the Government Medical Officers receive a salary of £400, rising by annual increments of £25 to £500, with partly furnished quarters, or a house allowance of £50. In some districts a medical officer is also a magistrate with a combined salary of £500, rising to £600, with free quarters. They are allowed private practice, so far as is consistent with the proper discharge of their duty to the Government, but in most districts the private practice is very small. In districts where there is no private practice, an allowance of £50 a year is granted. They are required either to take charge of hospitals or of districts, at the discretion of the authorities. The posts the Second Part are: Public Health and Epidemiology, Sanitary Law, Vital Statistics, and Sanitary Reporting.

University of Edinburgh.—Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh—viz., Bachelor of Science in Public Health and Doctor of Science in Public Health. A Diploma in Tropical Medicine and Hygiene is also granted. Candidates for the degree of B.Sc. in Public Health must be graduates in Medicine of a recognised University, and must pass two examinations, for the first of which they must, after graduation in Medicine, have worked for at least 20 hours per week during a period of not less than eight months, of which at least five consecutive months must be in the Public Health Laboratory of the University of Edinburgh and the remainder either there or in a laboratory recognised by that University; they must also have attended courses of instruction in Physics and Geology in some Scottish University. Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination, nor sooner than 18 months after having taken their degree in Medicine, and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian, Colonial, or Foreign University as may be approved for the purpose by Edinburgh University, each course consisting of 40 lectures at least; one of which courses shall deal with medicine and the other with engineering, each in its relation to public health. The subjects of examination include Laboratory work, Physics, Geology, Medicine in its application to Public Health, Sanitation, Sanitary Law, and Vital Statistics. Graduates who have held the degree of B.Sc. in Public Health from the University of Edinburgh for a term of five years may offer themselves for the degree of D.Sc. in Public Health in that University. They must then present a Thesis and pass an examination in Public Health. The fees are £4 4*s.* for the First and £5 5*s.* for the Second B.Sc. Examinations, and £15 15*s.* for the degree of D.Sc.

University of Aberdeen.—The Diploma in Public Health (D.P.H.) is conferred only on graduates in Medicine of a University in the United Kingdom not less than 12 months after medical graduation. Every candidate must produce evidence of having complied with the following requirements: (1) A course or courses of instruction consisting of not fewer than 50 meetings dealing with public health in relation to the administrative and other duties of a medical officer of health, such course or courses to be given by a teacher or teachers in the department of public health of a recognised medical school. (2) Practical instruction within a laboratory or laboratories approved by the University, in (*a*) Bacteriology, (*b*) Physics and Chemistry, (*c*) Parasitology, such instruction to extend over not less than six months or two academic terms. (3) Practical Instruction, Clinical and Administrative, within (*a*) a hospital for general infectious diseases—not less than thrice weekly; (*b*) a hospital or sanatorium or treatment centre for tuberculosis—not less than once weekly; (*c*) a hospital or treatment centre for venereal diseases—not less than once weekly; such instruction in each group to extend over three months. (4) Practical instruction and experience during not less than three months in the duties, routine and special, of public health administration, under the personal supervision of a medical officer of health or other medical officer, or, alternatively, that the candidate has held, within the British Dominions, for a period of not less than three years, an appointment as medical officer of health of a sanitary district with a population of not less than 15,000. (5) Practical instruction in: (*a*) Mother and Child Welfare at a Centre or Centres in a Welfare Scheme conducted or approved by a Local or Sanitary Authority—not fewer than ten meetings; (*b*) School Hygiene and Medical Inspection of School Children—not fewer than six meetings; (*c*) Drawing and Interpretation of Plans—not fewer than six meetings. The fee for the examination is £4 4*s.* for each part, or £8 8*s.* for the whole examination.

University of Dublin (Trinity College).—The Diploma in Public Health is conferred, after examination, on the following conditions. The candidate must be a registered medical practitioner and have obtained a registrable qualification at least nine months before the second part of the examination. The candidate must have completed, subsequently to obtaining a registrable qualification, four months' practical instruction in a chemical and bacteriological laboratory, or laboratories, approved by the University, must have studied practically outdoor sanitary work for six months under an approved officer of health, and must have attended for three months at a fever hospital where opportunities are afforded for the study of methods of administration. A special prospectus and a list of recognised laboratories may be obtained by application to the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland.—At this University there is a Diploma in Public Health, a B.Sc. in Public Health, and a D.Sc. in Public Health. The Diploma may be granted to matriculated or non-matriculated students of the University who shall have completed approved courses of study and shall have passed the prescribed examinations, provided that it shall not be granted except to a registered medical practitioner. Candidates may present themselves for the examination after an interval of not less than 12 months from the time of obtaining a registrable qualification. The curriculum extends over a period of not less than nine calendar months. Every candidate must produce a certificate that he has attended practical instruction in a laboratory, approved by the University, in Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man. The examination consists of two parts, which may be passed separately or together. Part I. comprises the following subjects: Chemistry, Meteorology and Climatology, and Sanitary Engineering and Architecture. Part II. comprises the following subjects: Bacteriology, Hygiene, Sanitary Law, and Vital Statistics. The examination in each part will be oral and practical as well as written.

For the B.Sc. in Public Health a candidate shall not be admitted unless he (*a*) shall have received the degrees of M.B., B.Ch., and B.A.O. at least one year previously; (*b*) shall have pursued an approved course of study in the Faculty of Medicine; and (*c*) shall have passed the prescribed examination. In addition to D.P.H. course the candidate will be required to take up (1) a Special Course of Pathology; (2) Bacteriology: and (3) Advanced Course in Hygiene. Each of these courses lasts three months.

University of Belfast.—A Diploma in Public Health is given by examination. Every candidate must produce evidence that, after obtaining a registrable qualification, he has during six months received practical instruction in an approved laboratory in which Chemistry, Bacteriology, and the Pathology of the diseases of animals transmissible to man are taught. After obtaining a registrable qualification every candidate must produce evidence that he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. The examination must have extended over not less than four days, one of which shall have been devoted to practical work in a laboratory, and one to practical examination in, and reporting on, subjects which fall within the special outdoor duties of a medical officer of health. The examination will be held in two parts, in March and in June. The first part of the examination will have reference to the general principles of sanitary science and the second part to State Medicine and to the applications of Pathology and Sanitary Science. The fee for each part is 1 guinea.

Assistant at the Medical Research Institute, Lagos, and Medical Officers of Health at various places), irrespective of the seniority of the officer holding the appointment. Staff pay at the rate of £150 a year is also attached to these posts; and the holder of the appointment draws half of the staff pay during leave of absence, the remainder being drawn by his locum tenens.

Leave and Passages.—The ordinary tour of residential service is 18 months, followed by leave with full pay during the voyages to and from England, and for four or two months clear in England, according as the officer is returning for further service in West Africa or not. Leave granted on the understanding that an officer will return is known as "return leave," and any pay drawn in respect of such leave is liable to be refunded if he does not return. Leave may be extended with half pay for a period not exceeding four months on the ground of ill-health, or without pay on that or other grounds. Free passages are given to all officers who are granted leave, and free passage is also given on first appointment, subject to the officer signing an agreement under which he is liable to refund its cost if he relinquishes his appointment for any other reason than physical or mental infirmity, or is removed for misconduct, within three years from the date of his arrival in West Africa. Half pay is given during the voyage out on first appointment.

Private Practice.—All officers of the Staff, except Principal Medical Officers, Deputy Principal Medical Officers, Provincial Medical Officers, Sanitary Officers, and a few other officers holding special appointments, are at present allowed to take private practice, provided that it does not interfere with the efficient performance of their official duties, but it is within the power of the Governor to withdraw or suspend the privilege in such places and for such periods as he may consider desirable. Private practice does not exist at the majority of stations, and as a general rule, subject to the exigencies of the service, stations where there is private practice are allocated to senior members of the staff.

Pensions and Gratuities.—These vary in accordance with the regulations of each Colony, but generally speaking an officer on attaining the age of 50 years, or after 18 years' service (of which at least 12 must have been residential) is qualified for a pension calculated at one-fortieth of the last annual[1] salary for each year of service. If invalided after a minimum of seven years' service, he is qualified for a pension calculated at the same rate. If invalided before completing seven years' service, he is qualified for a gratuity not exceeding three-quarters of a month's salary for each six months of service; provided that he has been confirmed in his appointment. For the purpose of calculating the amount of these pensions and gratuities, leave of absence without salary is not counted, while leave with half salary is counted at the rate of one month for every two months of such leave. An addition, representing the value of free quarters, is made to the officer's salary. This addition is as follows: To salaries of £400 a year, an addition of £10; to salaries above £400, but not exceeding £500, an addition of £50; to salaries above £500, but not exceeding £700, an addition of £60; to salaries above £700, but not exceeding £900, an addition of £70; to salaries exceeding £900, an addition of £80. In addition to the ordinary regulations, an officer of the West African Medical Staff enjoys the following special privilege. At the end of nine years (of which not less than six must have been residential) he will be permitted to retire with a gratuity of £1000, or at the end of 12 years (of which not less than eight must have been residential) with a gratuity of £1250. All claims to pensions are, however, forfeited on the receipt of such a gratuity. In the event of an officer dying in the service after completing the period of residence qualifying him for the smaller or the larger of these gratuities, a sum equal to the gratuity in question will be paid to the credit of his estate. Officers are not allowed to take their wives out with them until they have acquired experience of the local conditions, and have obtained the sanction of the Governor. Passages for wives and children are not provided.

Candidates for medical appointments in West Africa are allowed to express a preference for any particular Colony or Protectorate, and their wishes in this respect will be borne in mind and met as far as possible, but they are liable to be posted in the first instance, or transferred afterwards if necessary, to any other West African Colony or Protectorate at the discretion of the Secretary of State. Candidates who wish to be posted to the Northern Provinces of Nigeria should be able to ride. Candidates should on no account apply for, or accept, a West African appointment in the expectation of ultimately being transferred elsewhere, as the number of such transfers is exceedingly small. No applications for transfer can be entertained until an officer has served for five years in the West African Medical Staff, and officers desiring to be transferred must be prepared to find that medical salaries in other Colonies are lower than in West Africa. Only a small proportion of applicants succeed in obtaining a transfer. Officers who may be transferred to pensionable appointments under the Crown elsewhere than in West Africa do not forfeit their claim to pension in respect of their West African service on final retirement, provided they have been members of the Staff for at least 12 months.

Instruction in Tropical Medicine.—Every candidate selected for appointment will, unless the Secretary of State decides otherwise, be required to undergo a course of instruction for two or three months either at the London School of Tropical Medicine, Endsleigh-gardens, Euston-square, N.W. 1, or at the Liverpool School of Tropical Medicine at the University of Liverpool. The cost of tuition will be borne by the Government, but candidates must make their own arrangements for board and lodging; an allowance of £3 a week will be paid to them monthly in arrear for this purpose. A daily allowance of 5*s.* (but no salary) will be paid to each candidate, monthly in arrear, during the course, and may be continued subsequently up to the date of embarkation. These payments must be refunded by the candidate if he declines to accept an appointment in any of the Colonies or Protectorates for which he may be selected, if he fails to obtain a certificate showing that he has satisfied the school authorities, or if he relinquishes the West African service for any other reason than mental or physical infirmity, or is removed for misconduct, within three years of the date of his arrival in West Africa. If at the end of the session there exist no vacancy in the staff to which a candidate can be appointed, he will be placed in a Reserve and granted an allowance at the rate of £200 a year until the occurrence of a vacancy.

Course of study for higher scale of salary.—The approved course of study is the three months' course of the West London Post-Graduate College or the London School of Clinical Medicine, Greenwich, in clinical medicine, clinical surgery, and pathology. Officers are allowed to substitute for this course either the course of study and examination for a recognised diploma or degree in public health, sanitary science, or State medicine; the course of study and examination for a further medical or surgical diploma or degree; or if the Governor, on the recommendation of the Principal Medical Officer, approves—a course of study in some special branch of medical or surgical practice (e.g., ophthalmology, dermatology, genito-urinary diseases), or an advanced course at the London or Liverpool School of Tropical Medicine. Whichever of these courses of study is selected, the necessary tuition and examination fees will be paid by the Colonial Government except in the event of an officer's deciding to enter for a further medical or surgical diploma or degree.

Owing to the wastage of war and the lapse of periods of service there are many vacancies in the Colonial service, so that the age limits laid down for Colonial appointments are not always insisted upon. In the near future opportunities may be given to Colonial officers for research work, and their coming into line with the conditions in the naval and military services is very much needed.

DIPLOMAS IN STATE AND TROPICAL MEDICINE.

As usual we include in the Students' Number of THE LANCET an epitome of the instruction given at various universities and centres of medical education to medical men desiring to obtain diplomas in sanitary science, public health, State medicine, and tropical medicine.

Resolutions, designed with a view of ensuring "the possession of a distinctively high proficiency, scientific and practical, in all the branches of study which concern the public health," have been adopted at various times by the General Medical Council from 1902 to 1911. Certain universities and corporations grant qualifications in Tropical Medicine which have not as yet been made registrable by statute.

University of Oxford.—An examination, conducted partly in writing, partly vivâ voce, and in each subject partly practical, is held in Michaelmas and Trinity Term in the following subjects:—General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary

---

[1] Except that the pension of an officer who has been promoted within three years of his retirement is calculated on the average of his salary for the last three years.

University of Melbourne.

The University of Melbourne[3] was incorporated by Act of the Victorian Legislature in 1853. The Medical Act of 1890, substantially amended in 1906, set up the Medical Board of Victoria to register legally qualified medical practitioners. A five years' graded course is required with legal qualification given in a country which permits Australian graduates to register without further examination. All persons registered in the United Kingdom are entitled to register on personal attendance. Fee £5 5*s.* Certificate 10*s.* 6*d.* extra.

Preliminary Examination.—All candidates must possess the School Leaving Certificate, which is based on education in a secondary school during four years. The Intermediate Certificate must have been taken at least a year before the School Leaving. English is compulsory at the higher standard; Latin and geometry with trigonometry at the lower.

M.B., B.S.—The course extends over five calendar years, and is divided into two equal parts, hospital practice being confined to the second half. The first year (Division I.) is devoted to natural philosophy, chemistry, zoology, and botany; the remainder of the first half (Division II.) to anatomy (including histology) and physiology (including biochemistry). Two complete courses of dissections are compulsory. Hospital practice extends through Divisions III. and IV. The general hospitals ranking as clinical schools are the Melbourne Hospital, the Alfred Hospital, and the St. Vincent's Hospital. The recognised special hospitals include the Women's Hospital, the Children's Hospital, the Eye and Ear Hospital, the Infectious Diseases Hospital, the Receiving House, and Acute Mental Hospital. A full clinical curriculum is arranged, both general and special, with clinical lectures. In Division III. (lasting one year) courses of lectures are given in pathology (with practical work in histology and in bacteriology), in therapeutics, public health, materia medica and pharmacy, and regional and applied anatomy, and examination in all these subjects follows immediately. In Division IV., lasting a year and a half, systematic lectures are almost entirely confined to the first year and include medicine, surgery, and forensic medicine. Lectures on obstetrics and gynæcology are given in Division III., but the examination in these subjects is postponed till the final at the end of the course, which also includes the subjects of Division IV. Short courses of lectures are given in venereal diseases, anæsthetics, and medical ethics. Clinical medicine and clinical surgery rank as separate subjects in the finals.

Honour examinations with exhibitions are held in nearly all subjects of Divisions I., II., and III., and there is a final honour examination with scholarships in medicine, in surgery, and in obstetrics and gynæcology.

The yearly fee payable to the University is £23, with a sports fee of 1 guinea and a club-house fee of 1 guinea. The hospital and pharmacy fees in Divisions III. and IV. amount to £69 6*s.* The total fees are £194 16*s.* The degree fee for M.B., B.S. is 7 guineas.

The number of students for the full course in 1920 was 732. Provision is also made for instruction to dental students, massage students, single subject students, &c.

M.D.—Candidates must be Bachelors of Medicine of two years' standing. They may proceed either by thesis or by examination. The thesis must be a substantial contribution to medical knowledge. The examination includes medicine, with either obstetrics and medical gynæcology, or diseases of children, or diseases of the nervous system, including insanity. Subject to a dispensing power in the case of theses of great merit, all candidates must pass an examination in clinical medicine. The fee for examination and degree is 10 guineas.

M.S.—Candidates must be Bachelors of Surgery of two years' standing. Part I. of the examination includes surgical anatomy and surgical pathology. Part II. includes surgery in all branches. The two parts may be taken together or separately. No candidate can pass in Part II. who has not passed in Part I. The fee for examination and degree is 10 guineas.

Diploma of Public Health.—Granted under conditions agreeing with those in the United Kingdom. Fees for instruction are 32 guineas, apart from fever hospital practice. The fee for examination is 10 guineas, for diploma 3 guineas.

Diploma of Tropical Medicine.—Candidates must be qualified medical practitioners, and must have passed Part I. for D.P.H. or have undergone a special training is lieu thereof. They are trained in tropical medicine at the Australian Institute of Tropical Medicine, Townsville, Queensland, having a three months' course of theoretical and practical instruction, followed by a three months' clinical course in the Townsville Hospital. The examination is conducted at the Institute. Fee for preliminary course is £2 2*s.*; for course at institute, 10 guineas; for examination and diploma, 5 guineas.

Affiliated Colleges.—Trinity College (1872), Ormond College (1879), Queen's College (1888), and Newman College (1918) are affiliated to the University and have medical tutors.

University of New Zealand.

The University of New Zealand was established by Act of the New Zealand Legislature in 1870. The Medical Act of 1908 provided for the registration of medical practitioners. The University has no fixed home or buildings; it is an examining body with four affiliated colleges—namely, University of Otago, Dunedin; Canterbury College, Christchurch; Auckland University College; and Victoria University College, Wellington. The degrees of M.B., Ch.B., M.D., and B.D.S. are conferred, and the subjects of study are Biology, Physics, Physiology, Medicine and Surgery, Ophthalmology, Chemistry, Bacteriology and Public Health, Anatomy, Pathology, Midwifery and Gynæcology, and Dentistry. The agent in England is Mr. J. W. Joynt, M.A., 88, Gower-street, London, W.C. 1.

University of Sydney.

The University of Sydney[4] was incorporated by Act of the New South Wales Legislature in 1850. The Medical Practitioners Act of 1898 provides for the registration of legally qualified medical practitioners.

Matriculation Examination.—English, Mathematics, Latin and another language other than English are required, three at the Higher standard.

M.B., Ch.M.—The course of study extends over a period of five years. Five degree and a final examination are held; (1st year) in physics, chemistry, botany and zoology; (2nd year) in anatomy and physiology; (3rd year) in the entire subjects of anatomy and physiology, every part of the body having been dissected at least once; (4th year) in pathology, surgical anatomy and operative surgery, materia medica, and therapeutics; (5th year) in medical jurisprudence and public health; (final) in medicine, surgery, obstetrics, and gynæcology. Certificates of proficiency in vaccination and anæsthetics are required. The fee for each degree is £10. The number of students attending degree courses during 1920 was 991—860 men and 131 women.

M.D.—Candidates must, after obtaining the degree of Bachelor, have spent at least two years in medical or surgical practice or in approved study. Examination is written or oral in one of the following subjects: medicine, medical jurisprudence and public health, surgery, obstetrics and gynæcology; or in any of the scientific subjects included in the medical curriculum.

---

[3] The University Registrar is Mr. J. P. Bainbridge, J.P. The Melbourne University Calendar (1921) is a volume of 956 pp., printed for the University by Ford and Son, Drummond-street, Carlton, Melbourne. Price 3*s.*

[4] The University Warden and Registrar is Mr. H. E. Barff, M.A. The Calendar of the University of Sydney is printed for the University by Angus and Robertson, Ltd., Sydney. Price 2*s.* 6*d.*

15,000. (iii.) Of having, subsequently to having obtained a registrable qualification to practise Medicine, attended at least twice weekly during a period of not less than three months a practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration. In connexion with this degree the various metropolitan medical schools hold regular classes under teachers of Public Health and Sanitary Science, such instruction being also used to obtain the various diplomas of other Universities and of those Royal Corporations which grant them.

University of Durham.—Candidates for the degree of Bachelor of Hygiene (B.Hy.) must be at least 22 years of age, registered, and a graduate in Medicine of a recognised university. They must spend six months at Newcastle-upon-Tyne studying Comparative Pathology, Practical Bacteriology, Sanitary Chemistry, and Physics, and have to pass an examination in Sanitary Chemistry, Physics, Comparative Pathology, Sanitary Legislation, Vital Statistics, Nosology, Climatology, Meteorology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene. The fee for the examination for the degree of B.Hy. is £10 10*s.* and for the degree £6 6*s.* Candidates for the degree of Doctor of Hygiene (D.Hy.) shall be Bachelors of Hygiene of two years' standing, and shall be required to satisfy the Examiners that they have conducted original research in the subject of Public Health. The fee for the examination for the degree of D.Hy. is £20 and for the degree £10. The regulations for examination for the Diploma in Public Health (D.P.H.) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised University and the course of study need not be passed at Newcastle-upon-Tyne. The fee for the examination is £10 10*s.* and for the diploma £3.

Victoria University of Manchester.—An examination in Public Health is held twice yearly. The examination is in two parts and is written, oral, and practical. Candidates may present themselves for Parts I. and II. separately or at the same time provided that no candidate be admitted to Part II. unless he has already passed in Part I. No candidate's name will be published until he has satisfied the examiners in both parts of the examination. The fee for each part is £8 8*s.*, and must be paid on or before July 1st in each year. For any subsequent examination in the same part the fee will be £4 4*s.* Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health. The examinations will begin about the middle of March and the middle of July in each year. Holders of the Diploma in Public Health are eligible for examination for the Certificates in School Hygiene and Factory Hygiene after attending the prescribed periods of study and hospital practice.

University of Birmingham.—The University grants a degree of B.Sc. in Public Health and also a Diploma in the same subject on the following conditions: Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health, except that after graduating in Medicine all courses of study must be taken out in the University, and they must, in addition, have attended a three months' course of Geology in the University. The examinations will be held in the months of March and June and will consist of two parts, each part being written, oral, and practical. No candidate will be allowed to pass Part II. until he has passed Part I. Candidates may enter for Parts I. and II. separately or at the same time. The fee for each part of the examination is £6 5*s.* Medical Officers of the Royal Navy who have attended courses in Hygienic Chemistry Bacteriology, and Public Health at the Naval Medical School, Greenwich, will be admitted to the examinations for the Diploma in Public Health, whether they have previously been students at the Birmingham School or not; and the same applies to officers of the Royal Army Medical Corps who have studied Chemistry and Bacteriology at the Staff College and pursued the further course of study approved by the General Medical Council.

University of Liverpool.—The University grants a Degree in Hygiene (M.H.) and a Diploma (D.P.H.), and every facility is afforded for training in Sanitary Science and State Medicine. The curriculum for the Degree extends over a period of two years, the first of which is devoted to laboratory instruction and practical classes (including those for the Diploma); the second being devoted to advanced study and research. The D.P.H. curriculum fees are: Chemistry, £7; Bacteriology, £7; Practical Sanitation, £15; Infectious Diseases, £4 4*s.*; Genetics and Environment, £3; Parasitology, £4 4*s.* The courses may be taken out at any time, and students are allowed to work daily in the laboratories.

The University grants a Diploma in Tropical Medicine. Three courses of instruction are given every year. Two of these last for three full months—the Lent Course from Jan. 6th to April 5th and the Autumn Course from Sept. 15th to Dec. 13th. The Third Course, an Advanced Course, lasts one month, from June 1st to the 30th. At the end of each full course an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The examination lasts three days and consists (1) of papers on Tropical Medicine, Tropical Pathology, and Tropical Sanitation and Entomology respectively; (2) of a clinical examination; and (3) of an oral examination. The advanced course consists entirely of Practical and Clinical Laboratory Work, given at the laboratory at the University. The fee for the full course of instruction is £18 4*s.*, with an extra charge of 10*s.* 6*d.* for the use of a microscope if required. Applications should be made to the Dean of the Medical Faculty, University of Liverpool. Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for research work is to be had at the University Laboratory. The Mary Kingsley Medal is awarded by the school for distinguished work in connexion with Tropical Medicine.

University of Leeds.—The University grants a Diploma in Public Health, and every facility is afforded for training in Sanitary Science and State Medicine. The examination, which is held twice in each year—namely, in June and December—is in two parts, and is written, oral, and practical. Candidates may present themselves for Part I. (Sections 1 and 2), Part I. (Sections 3, 4, and 5), and II. separately or at the same time, provided that no candidate be allowed to pass in Part II. unless he has already passed in Part I. *Fees*—The fee for each part is £6 6*s.*, and for any subsequent examination in the same part £4 4*s.* Instruction in Sanitary Chemistry and Bacteriology is given in the second and third terms. Practical work under arrangement with the Leeds City Council. Prospectus can be obtained from the Dean of the Medical School.

University of Bristol.—Diploma in Public Health. Candidates must be at least 23 years of age, shall be fully registered medical practitioners of not less than 12 months' standing as such, and shall have passed the examination prescribed by regulation. The examination is divided into two parts. The subjects of the First Part are Chemistry as applied to Public Health and Pathology and Bacteriology. Candidates for the First Part shall, during six months after having obtained a registrable qualification, have received practical laboratory instruction in Hygienic Chemistry, in Bacteriology, and in the Pathology of the Diseases of Animals Transmissible to Man. The subjects of with English and one modern language. This readjustment gives a final year confined to hospital work, including medicine, surgery, obstetrics, gynæcology, ophthalmology, oto-laryngology, pædiatrics, pathology, and dermatology. The third year now embraces anatomy (neurology), physiology, general pathology, bacteriology, chemistry (physiological and clinical), parasitology, pharmacology, and clinical microscopy. During this year students begin to visit the hospitals and receive instruction in small groups in the elements of clinical medicine and clinical surgery. Examinations are held in the subjects of each successive year. The total faculty fees for the medical course of six years are $1200, payable in six instalments of $200 each, or in 12 instalments of $102 each. The degree fee is $30. 724 medical students were enrolled in the session 1920–21.

D.P.H.—This course, cancelled during the war, has now been resumed.

New Brunswick, Council of Physicians and Surgeons.

The Council of Physicians and Surgeons of New Brunswick is empowered by the Medical Act to issue a licence (L.M.S.) conferring the legal right to practise. The usual matriculation examination is required and the graded collegiate course comprises five sessions of not less than eight months each. The examinations are held twice a year at St. John, N.B., the fee being $30. Candidates may appear for the primary examination at the end of the second year of study. The fee for the licence is $3 and the registration fee $40.

Nova Scotia, Provincial Medical Board.

A licence (L.M.S.), legally entitling to practise, is issued by the Provincial Medical Board of Nova Scotia to those who have satisfied requirements in respect to preliminary and professional education. After registration in the Medical Students' Register (fee $25) a course of at least five full years in medicine must be taken. Graduates of medical schools recognised by the Board who can submit satisfactory schedules of studies are admitted to the third (final) professional examination (fee, including registration, $75). All applicants for registration must take this examination except licentiates of the General Medical Council of the United Kingdom and of the Medical Council of Canada, who are admitted to registration without examination upon payment of a fee of $50. The registrar of the Board is Dr. W. H. Hattie, Halifax, N.S.

University of Toronto.

The University of Toronto,[8] Ontario, took its title in 1849, a Royal Charter having been granted in 1827. The Faculty of Medicine was re-established in 1887 under the Federation Act. Victoria College (1892), Trinity College (1904), and St. Michael's College (1907) are integral parts of the University.

Preliminary Examination.—The matriculation certificate of the University is required from entrants unless they are graduates in Arts of a Dominion or British University or possess a certificate of entrance into the Faculty of Education.

In the Session 1922–23 the standard of Entrance will be raised to Honour Matriculation in English, Mathematics and one language. In the first three years, the fundamental medical sciences, Anatomy, Physiology and Biochemistry, are thoroughly covered, while in the three final years, Medicine, Surgery and other clinical subjects, Pathology and Pathological Chemistry are taught. The final year is almost entirely clinical in character. Optional courses are supplied to enable students to do advanced work in special subjects. A Post-Graduate Course of one year has been arranged in Radiology, at the end of which a diploma is granted. The fee for the course is $150.

M.B.—Six examinations are taken in succession at the end of the session. The early years aim at giving such a training in sciences as is now exacted of those who desire to obtain a British as well as a Canadian qualification. The final year includes courses on anæsthesia, dentistry, medical ethics, history of medicine, and life insurance. The annual fee for regular students with one annual examination is $150. Combined courses of B.A., M.B. and B.Sc., M.B., lasting seven years, are also arranged. There is residence for about 150 men and three houses near to the University. Each male student proceeding to a degree must take physical training, the character to be determined by medical examination in the first two years of his attendance.

M.D.—One year must elapse after obtaining the M.B. degree and an approved thesis submitted.

D.P.H.—Candidates must be graduates in medicine of this or some other University. The curriculum extends over a winter session of eight months and a summer session of three months. The fee for the course is $150 and for the diploma $20.

NEAR EAST.

Registrable Degree.—University of Malta, M.D.

University of Malta.

The University of Malta (Valletta) was added in 1898 to the list of institutions recognised by the English Royal Colleges. Study in the Faculty of Medicine and Surgery[9] is open to matriculated students who have attended a three years' preparatory course in the Faculty of Science. Matriculation includes English, Italian, and Latin, while history is also necessary to comply with the G.M.C. regulations. The preparatory course in science comprises English and Italian literature, philosophy, physics, botany, zoology, inorganic chemistry, organic chemistry, human anatomy, general histology, and dissection. Medical botany is taught at the Botanic Garden. The academical course of medicine and surgery extends over four years, the first year being devoted to anatomy, physiology, histology and dissection, and the final year including clinical medicine, surgery, and midwifery, along with skin diseases, mental diseases, operative surgery, gynæcology, and forensic medicine, and continued attendance at the clinical laboratory and the hospital. The degree of *M.D.* is conferred at the end of the fourth year of the course, after a final written, oral, and practical examination.

FAR EAST.

Summary of Registrable Degrees.—Ceylon: Medical College, L.M.S. Hong-Kong: University of Hong-Kong, M.B., B.S., and M.D., M.S. India: University of Bombay,[10] (1) L.M.S., (2) M.B., B.S., (3) M.D., (4) M.S.; University of Calcutta, (1) L.M.S., (2) M.B., (3) M.D., (4) M.S., (5) M.O.; University of Lucknow,* M.B., B.S.; University of Madras,[11] (1) M.B., M.S., (2) M.B., B.S., (3) M.D.; Punjab University, (1) L.M.S., (2) M.B., (3) M.D., (4) M.S. Straits Settlements: King Edward VII. Medical School, Singapore, L.M.S.

University of Bombay.[12]

Candidates for the *M.B., B.S.* must have passed the first year arts examination or its equivalent, and be engaged during five University years in professional study at a medical college recognised by the University. Three examinations are held: the first, or preliminary scientific; the second, or intermediate; and the third, or final; each of them twice in the year. The two former are of the usual character. The final is divided into two parts, which may be taken together or separately two years after the intermediate. Part I. includes medicine, medical jurisprudence,

---

[8] The Secretary of the Faculty of Medicine is Dr. E. S. Ryerson.

[9] Statute of the University of Malta, 1921, Government Printing Office, Malta, price 1s.

[10] If obtained after June 25th, 1912, the degree must have been registered in the Presidency.

[11] If obtained after June 1st, 1916, the degree must have been registered in the Presidency.

[12] The Registrar of the University is Mr. F. M. Dastur, M.A. The Bombay University Calendar (1920), vol. i., is a book of 662 pp., printed at the Government Central Press, Bombay.

Royal College of Physicians of London and the Royal College of Surgeons of England.—The following are the regulations for obtaining the Diploma in Public Health: The examination consists of two parts. The first part of the examination takes place in January and July, and the second part in January and July. The fee for each part is £10 10*s*., except for those who are diplomates of the Royal Colleges, who pay £6 6*s*. for each part. A candidate intending to present himself must give 14 days' written notice to the Secretary, at the Examination Hall, Queen-square, London, W.C. 1. He will be admissible to examination in Part I. on producing evidence (1) of having been in possession of a registrable qualification for at least 12 months; and (2) of having attended thereafter practical instruction in a laboratory recognised by the Examining Board in England for at least 240 hours during a period of six months. A candidate will be admitted to Part II. of the examination on producing evidence (1) of having been diligently engaged in acquiring a practical knowledge of Public Health administration during six months, which may be reduced to three months under certain specified conditions; and (2) of having attended during three months the clinical practice of a hospital for infectious diseases.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, Royal Faculty of Physicians and Surgeons of Glasgow.—All candidates for the Diploma in Public Health must have a qualification which has been registered under the Medical Acts. Candidates must have attended not less than four calendar months' practical instruction in Chemistry and Bacteriology in a recognised laboratory or laboratories, must have studied outdoor sanitary work for six months under a medical officer of health or other sanitary officer; and must give evidence of attendance for three months at the practice of a Hospital for Infectious Diseases, at which he has received instruction in the methods of administration. The examination consists of two parts, and candidates may enter for both at one period or for either separately. The First Part includes (*a*) Laboratory Work (Chemistry and Bacteriology), (*b*) Physics and Meteorology; and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Written and Oral Examinations on Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation. The fee is 12 guineas for both examinations, or 6 guineas for either of them. A fee of 3 guineas is payable by rejected candidates for either examination. The examination is held twice yearly, in May and October. The published regulations provide detailed synopses of the subjects of examination. The Registrar for Edinburgh is Mr. D. L. Eadie, 49, Lauriston-place, and for Glasgow Mr. Walter Hurst, 242, St. Vincent-street.

Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland.—Every candidate for the Diploma in Public Health must be a registered medical practitioner. He must subsequently to qualification (1) receive four months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man; and (2) during six months practically study outdoor sanitary work under a medical officer of health, and shall as an additional requirement attend a hospital for infectious diseases. Candidates are examined on four days, commencing on the first Monday of February, May, and November. The examination comprises the following subjects: Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Sanitary Law, and Bacteriology. The fee for the examination is £10 10*s*. For further particulars apply to Alfred Miller, O.B.E., Secretary, Committee of Management; Office, Royal College of Surgeons, Dublin.

REGISTRABLE COLONIAL AND FOREIGN MEDICAL DEGREES.

UNDER the Medical Act, 1886, a number of medical diplomas granted in British possessions entitle their holders to be registered without further examination in the Colonial List of the (British) Medical Register. The condition attached to such registration is that the holder of the colonial diploma obtained it when he was not domiciled in the United Kingdom or in the course of a period of not less than five years during the whole of which he resided out of the United Kingdom. Some account is here given of the diplomas and of the course of study required to obtain them.[1] The information has in most cases been supplied or confirmed by the authorities of the university or corporation, to whom our best thanks are offered.

AUSTRALASIA.

Summary of Registrable Degrees.—New South Wales: University of Sydney, (1) M.B., (2) M.D., (3) Ch.M. New Zealand: University of New Zealand, (1) M.B., Ch.B., (2) M.D. South Australia: University of Adelaide, (1) M.B., B.S., (2) M.D., (3) M.S. Victoria: University of Melbourne, (1) M.B., (2) M.D., B.S.

University of Adelaide.

The University of Adelaide[2] was established by Act of the South Australian Legislature in 1874. In 1883 Sir Thomas Elder gave £10,000 for the foundation of a school of medicine, and in 1897 a further sum of £20,000 under his will. The Medical Acts of 1844 and 1880 set up a South Australian Medical Board to issue certificates of legally qualified medical practice.

Preliminary Examination.—Before entering upon the medical course candidates must have passed the Senior Public Examination in at least five subjects, and the higher standard in physics, chemistry, and biology, either of the Higher Public Examination or first year Science.

M.B., B.S.—The five years' course includes five examinations held in November of each year. At the first the subjects are anatomy and dissections, physiology, organic chemistry, and physical chemistry; at the second, anatomy, physiology, and materia medica; at the third, medicine, surgery (including clinical), regional and surgical anatomy, bacteriology, public health and preventive medicine; at the fourth, medicine (including clinical), surgery (including surgical anatomy and clinical surgery), pathology, obstetrics, and forensic medicine (including insanity); at the fifth, medicine (all branches), surgery (including surgical anatomy and operative surgery), gynæcology, ophthalmology, otology and therapeutics. The fee for each examination is £3 3*s*. and for the degree £5 5*s*. Fees for the five years' course of study amount to £145 19*s*.

M.D.—Candidates must have been Bachelors for at least nine academic terms, which may be shortened on the recommendation of the Faculty of Medicine. The subject of examination may be selected from the following: General medicine, diseases of the nervous system, pathology, obstetrics, State medicine. A thesis may be submitted. Fee for the examination £15 15*s*., for the degree £10 10*s*.

M.S.—The conditions are similar to those for the M.D. Choice of subject may be made from: Gynæcology, the surgery of the abdomen, the surgery of the special senses and throat; in addition to examination in the principles of surgery.

---

[1] Belgium no longer appears in this list as the Government of that country now requires British practitioners to obtain Belgian qualifications: consequently reciprocity between the two countries has come to an end, at any rate for the present. In the South African Union reciprocity already applies, but there are as yet no facilities for obtaining complete medical courses. In Spain there are good reasons for hoping that reciprocity may soon be an accomplished fact.

[2] The University Registrar is Mr. C. R. Hodge. The Calendar of the University of Adelaide (1921) is a volume of 534 pp., printed by W. K. Thomas and Co., Grenfell-street, Adelaide. Price 2*s*. 6*d*.

examination of the Science Faculty taking the medical student's group; it comprises anatomy, physiology, and materia medica, and the fee is Rs.30. The second examination is in pathology, forensic medicine, and hygiene, and is taken at the end of the third year; the fee is Rs.30. The final examination, for which the fee is Rs.40, is taken at the end of the fifth year and comprises the rest of the professional subjects.

King Edward Medical College, Lahore, trains students for the medical degrees of Punjab University. The college year consists of one long session of three terms. The course for the M.B., B.S. occupies five years, the fees being Rs.125, Rs.115, Rs.135, Rs.105, and Rs.110 in successive years. College scholarships are granted.

Registrable Foreign Medical Degrees.

Certain medical diplomas granted in foreign countries also entitle to registration in the foreign list of the Medical Register, provided that the holder is not a British subject or that, being a British subject, the diploma was obtained under domiciliary conditions similar to those attached to colonial diplomas.

Summary of Registrable Degrees (the date in parentheses being the year in which Part II. of the Medical Act. 1886, was applied to the country in question).—*Italy* (1901): Degrees of Doctor of Medicine and Surgery of all the Royal Italian Universities. *Japan* (1905): Degrees of Bachelor of Medicine (Igakushi) and Doctor of Medicine (Igaku Hakushi) of the Imperial Universities of Japan; and the Degree of Bachelor of Medicine (Igakushi) of any Government or Prefectural special medical college, or of a private special medical college designated by a Minister of Education of the Empire of Japan.

Italy.

The regulation for the medical diploma is fixed by Royal Decree dated August 9th, 1910, and is the same for each of the 20 universities and institutes where courses of study are arranged. These are in alphabetical order: Bologna, Cagliari (Sardinia), Camerino, Catania, Ferrara, Florence, Genoa, Messina, Modena, Naples, Padua, Palermo, Parma, Pavia, Perugia, Pisa, Rome, Sassari, Siena, and Turin. Camerino, Perugia, and Ferrara are "free" Universities, and supply a part only of the Medicine course.

The course covers six years, and embraces the following 20 constituent subjects: (1) experimental physics, (2) inorganic and organic chemistry, (3) botany, (4) zoology and comparative anatomy, (5) normal human anatomy (descriptive or systematic, macroscopic and microscopic), (6) physiology, (7) general pathology, (8) pharmacology and toxicology, (9) pathological anatomy and histology, (10) special medical (practical) pathology, (11) special surgical (practical) pathology, (12) medical clinics, general and special, (13) pediatric clinic, (14) surgical clinic, general, special and operative, (15) obstetric and gynæcological clinic, (16) ophthalmological clinic, (17) clinic of nervous and mental diseases, (18) hygiene and public health, (19) legal medicine, (20) dermatological and venereal clinic.

The distribution of these subjects over the six years varies somewhat at the different centres, but the official course at Siena may be taken as an example:—1st year: botany, zoology, normal human anatomy. 2nd year: normal human anatomy, general chemistry, experimental physics, embryology, experimental physiology. 3rd year: normal and topographical human anatomy, experimental physiology, bacteriology, general pathology. 4th year: materia medica, special medical and surgical pathology, pathological anatomy, medical and surgical clinic. 5th year: pathological anatomy, medical, surgical, ophthalmological, and dermatological clinic, hygiene and public health. 6th year: medical, surgical, nervous and mental, pediatrics, and obstetric clinic, legal medicine, operations, history of medical science. Twenty-six optional courses in special subjects can be attended by students of various years. The examinations are held in the latter half of October and June.

Japan.

The medical course is taken at the Imperial Universities of Tokyo, Kyoto, Kyushu and Tohoku, and at the Medical Colleges of Kyoto, Osaka, Chiba, Aichi, Nagoya, Okayama, Kumamoto, Nagasaki, Kanazawa, Niigata, Tokyo-Jikein, Formosa, Korea, and Mukden. Each includes institutes of anatomy, embryology, histology, physiology, medical chemistry, pharmacology, pathology, hygiene, microbiology, forensic medicine, diagnosis, medicine, surgery, ophthalmology, obstetrics-gynæcology, pediatrics, dermatology, oto-rhino-laryngology, orthopædic surgery, dentistry, psychiatry, and neurology. There is a four years' course of instruction, and yearly about 80 students graduate in medicine from each University or College.

DENTAL SURGERY.

University of Sydney.—A degree in Dental Surgery (B.D.S.) is granted after a four years' course following matriculation. A graduate in medicine is required to devote four terms to dental study before sitting for the degree of B.D.S.

University of Adelaide.—The four years' course for the B.D.S. is regulated by similar conditions to that for the M.B., B.S. Four examinations are held in November of successive years. The fee for each ordinary examination is £3 3*s.*, and for the degree £5 5*s.* Fees for the whole course amount to £95 11*s.* The subjects of the several examinations are set out on p. 185 of the Calendar.

University of New Zealand.—The dental degrees of this university carry with them the right of a place in the foreign list of the British Register.

McGill University, Montreal.—The degree of D.D.S. is granted on a four years' curriculum.

University of Toronto.—The degree of D.D.S. is granted on a five years' curriculum. Annual examinations are conducted under the joint auspices of the University and the Royal College of Dental Surgeons of Ontario.

University of Malta.—The University grants its diploma in dental surgery after examination to matriculated candidates producing evidence of four years' professional study and three years' instruction in mechanical dentistry.

TEACHING INSTITUTIONS IN DENTISTRY.

Dominions.

The Australian College of Dentistry, in connexion with the Melbourne Dental Hospital, trains candidates for the degrees of B.D.Sc. and D.D.Sc. Melb. Students indentured to the College pay £170 in two instalments of £85 each, or four instalments of £42 10*s.* The superintendent of the College is Mr. F. A. Aird, L.D.S., B.D.Sc.

United Dental Hospital of Sydney was established in 1901 to provide facilities for the students attending the University Dental School. The fee payable by University students for the dental practice of the hospital is £6 6*s.* per annum. The secretary is Mr. H. A. Clarke, F.I.A.A.

The Dental Department of McGill University, Montreal, was opened in 1903 at the request of the Dental Association of the Province of Quebec as a section of the medical faculty. An out-patient clinic in dentistry at the Montreal General Hospital provides the clinical material. Particulars from the Dean of the Dental Faculty.

Royal College of Dental Surgeons of Ontario has a school of dentistry in connexion with the University of Toronto. Practical work is carried out in the infirmary and laboratories of the College.

The conditions under which medical and dental practitioners with British qualifications may practise abroad are set out in the fifth edition (1921) of a report published for the General Medical Council by Messrs. Constable and Co., Ltd., 10, Orange-street, London, W.C. (price 2*s.* 6*d.*)

A thesis must be presented two months before the examination. The fee for the degree is £10.

Diploma in Public Health.—Candidates must be registered practitioners of not less than 12 months' standing. The examination is in two parts: (1) relating to the general principles of sanitary medicine; (2) relating to State medicine and to the application of pathology and sanitary science to public health. The fee is £10.

Affiliated Colleges.—Matriculated students are admitted to the following resident colleges—namely, St. Paul's College (Church of England), St. John's College (Roman Catholic), St. Andrew's College (Presbyterian), Wesley College (Methodist), the Women's College (undenominational), at which scholarships and bursaries are available.

Recognised Hospitals are the Royal Prince Alfred Hospital with medical school, the Sydney Hospital with clinical school, St. Vincent's Hospital, the Royal Hospital for Women, the Royal Alexandra Hospital for Children, the Glandesville and Callan Park Hospitals for the Insane, the Women's Hospital, the Renwick Hospital for Infants, and the South Sydney Hospital for Women.

BRITISH NORTH AMERICA.

Summary of Registrable Degrees and Diplomas.—Alberta: College of Physicians and Surgeons, Member. Manitoba: College of Physicians and Surgeons, Member; University of Manitoba, M.D., C.M. New Brunswick: Provincial Council of Physicians and Surgeons, L.M.S. Newfoundland: Medical Board, L.M.S. North-West Territories: College of Physicians and Surgeons, Member (when held in conjunction with the licence of Alberta or Saskatchewan). Nova Scotia: Provincial Medical Board, L.M.S.; Dalhousie University, M.D., C.M. (Halifax Medical College, M.D., C.M., if obtained prior to August 31st, 1911). Ontario: College of Physicians and Surgeons, Member. (To this can be added as additional qualifications the degrees in medicine of the Queen's University, Kingston; the Western University, London; and the University of Toronto.) Prince Edward Island: Medical Council, L.M.S. Quebec: McGill University, M.D., C.M.; Laval University, M.D.; University of Montreal, M.D. Saskatchewan: College of Physicians and Surgeons, Member.

Dalhousie University, Halifax, Nova Scotia.

The work of Halifax Medical College was discontinued in 1911, when instruction in all subjects of the medical curriculum was undertaken by Dalhousie University. The professional examinations are conducted conjointly by the university and the Provincial Medical Board of Nova Scotia (see below).

M.D., C.M.—In addition to the matriculation or preliminary examination candidates are required to pass five professional examinations. For admission to the classes of the third or any higher year the undergraduate must have passed in all the subjects of the preceding year. The curriculum for the third year still includes practical anatomy and advanced physiology, while the fifth (final) year subjects are given as: Surgical anatomy, operative surgery, clinical surgery, clinical medicine, clinical pediatrics, clinical obstetrics, practical obstetrics, clinical gynæcology, mental diseases, skin diseases, eye, ear, nose and throat diseases, dressing, clerking, vaccination, post mortems, hospital, medical ethics. To win distinction in any subject a mark of 75 per cent. or over is required. The total tuition fees in any year amount to $200 including registration, tuition, hospitals, laboratories, and the regular sessional examinations. There were 168 medical students of all years in 1920-21. Dean of the Faculty, John Stewart, M.B.Edin., LL.D.Edin. and Dal.: Secretary, Professor Fraser Harris, M.D., D.Sc. The regulations are subject to change owing to the institution of the six-year course beginning October, 1921.[5]

Queen's University, Kingston, Canada.

Queen's College, Kingston, was established by Royal charter in 1841, assisted by grants from the Presbyterian Church in Scotland. Classes in medicine were first held in the University in 1854. The Medical School, conducted for a time under the charter of the Royal College of Physicians and Surgeons at Kingston, became an integral part of the University in 1892. Kingston General Hospital (230 beds) is adjacent to the University buildings.

M.D., C.M.—Candidates for a degree must pass the Junior Matriculation of the University or its equivalent. The course comprises five sessions of eight months each. A combined B.A. and M.D. course may be taken in seven years. Foreign students must spend at least one full session in the University. Examinations are held at the end of each session. The average cost per session of eight months, including board and lodging, is $376–435. All students are expected to attend a church of the denomination to which they profess to belong.

D.Sc.—Granted on a thesis embodying original research of importance to medical science not earlier than two years after graduation. A reading knowledge of scientific French and German is required.

D.P.H.—The diploma is granted to those holding the M.D., or M.D., B.Sc., after examination following prescribed study, which includes six months with a recognised medical officer of health in the study of practical sanitation.

Laval University, Quebec.

Laval Catholic University[6] was incorporated by Royal Charter in 1852, absorbing the Quebec School of Medicine organised four years earlier. The first class graduated in 1855. The medical department was destroyed by fire in 1910.

M.B., M.D.—The entrance examination includes Latin, philosophy, and Canadian history, and its standard is prescribed by the College of Physicians and Surgeons of Quebec. The Faculty of Medicine confers a baccalauréat and a doctorat, the former after 2 years, comprising 6 terms of study, the latter after 3 further years. Examinations are held in June at the end of each year of study. The total fee for examinations is $15, for the diploma of bachelor $5, and for that of doctor $20. Fees paid by enrolled students for the medical course amount to $15 a term.

McGill University, Montreal.

The Faculty of Medicine of McGill University[7] arose out of the Montreal Medical Institution, organised as a medical school in 1823-24, and incorporated in the University in 1829.

Preliminary Examination.—Before registration an undergraduate in medicine must have passed the Matriculation Examination of the University or its equivalent. The examination is held twice yearly at McGill, and once at Calgary, Regina, Winnipeg, Toronto, St. John, and Truro. Also in June in London (apply to Secretary, Headmasters' Conference, 12, King's Bench Walk, E.C.). Latin, and either Greek, French, or German must be taken. For the Session 1922–23 Senior Matriculation, or one year in Arts covering English, History, Mathematics, Latin, French, German or Greek, Physics or Chemistry will be required for admission. Every student entering the University is required to pass a physical examination to detect defects and weaknesses amenable to treatment. Board and lodging can be obtained in private houses in the vicinity of the University at $40 a month upwards.

M.D., C.M.—The undergraduate course in medicine has been increased to six years by a pre-medical year devoted to chemistry, physics, and biology, paid by the student. In the hall of residence attached to the college lodging costs from $3 to $5 and board $8.40 a week, the hope being expressed that the last-mentioned figure may soon be reduced. Bequests have made it possible to reserve a "student's bed" at the College hospital, and to aid students in time of illness. A member of the board of the Woman's Hospital has given $1000 out of which small sums are paid as premiums to graduates and students of the College who invent or improve medical instruments or appliances. Furthermore, a prize of $50 is offered annually to the student, who on the vote of her colleagues and teachers best exemplifies the following qualities: "A good student, showing interest and industry in her work; reliability, cheerfulness, fairmindedness, tolerance, and capacity for team-work."

---

[5] The Calendar is printed by Wm. Macnab and Son, Halifax.

[6] The Secretary of the Medical Faculty is M. Arthur Vallée.

[7] The University Registrar is Dr. J. A. Nicholson, M.A., LL.D. The Annual Calendar of the Faculty of Medicine and Department of Dentistry is a volume of 99 pp., printed by the Gazette Printing Co., Ltd., Montreal.

DIPLOMA IN RADIOLOGY AND ELECTROLOGY.

IN June, 1919, the University of Cambridge instituted a diploma in radiology and electrology to be taken after a course of study extending over a period of six months or more. The lecture course in Part I. consists of physics and electro-technics with photography; in Part II., of radiology and electrology, in each case with special reference to diagnosis and treatment. Six months' clinical experience is required in the electrical department of a recognised hospital. Lecture courses are arranged twice a year alternately in Cambridge and in London. Apart from examination the diploma may be granted to a medical practitioner of not less than ten years' standing and five years' experience in radiology on presentation of a dissertation. Application to the Secretary, Dr. Shillington Scales, Medical Schools, Cambridge.

Medical News.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—The following appointments have been made in the Faculty of Medical Sciences: Mr. R. A. Dart and Mr. J. Shellshear to be senior demonstrators in anatomy; Dr. C. Da Fano to be senior lecturer in histology; Dr. Elizabeth Fraser to be senior assistant in zoology; and Mr. E. B. Verney to be assistant in physiology.—In connexion with the University College and University College Hospital Medical School War Memorial two publications are now in course of preparation; the first of these, the Pro Patria List, now contains upwards of 3000 names, and the War Memorial Committee are anxious to make it as complete as possible. Alumni, or the relatives of alumni, who served in the war, who have not yet received the Pro Patria questionnaire are therefore requested to communicate with the committee at once. The second publication is the War Memorial Album, designed to contain the records and portraits of those alumni who gave their lives during the war. Owing to changes of address it has hitherto been impossible to obtain full particulars or portraits of some 80 men who are known to have fallen. It is hoped that relatives who have not yet received the War Memorial Album form will also inform the committee without delay.

The Primary Fellowship Course.—The course in anatomy at University College will be resumed on Thurs., Sept. 1st, at 10 A.M.; the course in physiology on Wedn., Sept. 21st, at 2 P.M. Dr. D. T. Harris will be glad to see all students intending to take the physiology course on Thurs., Sept. 1st, in order to advise them with regard to their preparatory reading.

THE CENSUS RETURNS, 1921.—A preliminary report of the Registrar-General, issued on August 23rd, gives the population of England and Wales in 1921 as 37,885,242, being an increase of 1,814,750, or only 4·9 per cent. on the population in 1911. There is an excess of 1,720,802 females over males.

THE LATE LIEUT.-GENERAL SIR DAVID HENDERSON.—Lieut.-General Sir David Henderson, K.C.B., K.C.V.O., D.S.O., who died at Geneva on August 17th, after a long period of ill-health, had held the post of Director-General of the League of Red Cross Societies from May, 1919. He had previously become famous as Director-General of Military Aeronautics, which post he held, from its creation in 1913 till October, 1917.

DANGEROUS DRUGS ACT.—The Home Office has announced a provisional regulation extending the application of the Dangerous Drugs Act to the Isle of Man.

CHILDREN'S COUNTRY HOLIDAYS FUND.—Mr. Francis Morris, chairman of the Fund, writes calling attention to the urgent need for donations. A gift of £1 will still provide a fortnight in the country for a child from a London elementary school. Cheques, payable to the Earl of Arran, hon. treasurer, may be sent to 18, Buckingham-street, London, W.C.2.

CONSTRUCTIVE BIRTH CONTROL.—A society with this name was recently formally constituted when the following officers and committees were elected: President, Dr. Marie Stopes; Hon. Secretary, Mr. H. V. Roe; and Hon. Treasurer, Mr. Aylmer Maude. Among the vice-presidents are the following medical men:. Sir James Barr, Sir W. Arbuthnot Lane, and Sir Archdall Reid. A medical research committee includes Dr. Jane L. Hawthorne and Mr. E. B. Turner. Active work is projected to commence next October and a League of Nations Committee and a Political Committee are to be appointed.

DONATIONS AND BEQUESTS.—Mr. T. H. Kirkbride, of Leeds, who left estate of the value of £10,746, bequeathed £500 to the Leeds Public Dispensary, £100 to the Leeds Tradesmen's Benevolent Institute, £100 to the Wesleyan Foreign Mission, £100 to Dr. Stephenson's Home for Children, and the residue of his property to the Leeds General Infirmary.—The late Miss Kate Fyfe Grant, of Cullen, who died on July 9th, has bequeathed the residue of her estate, amounting to over £2000, to the University of Aberdeen for the purpose of founding bursaries in the Faculty of Medicine, to be called the "Grant Medical Bursaries." Preference will be given to candidates born in or having a substantial personal connexion with the parishes of Cullen or Huntly. One of Miss Grant's brothers was the late Dr. George Grant, of Huntly, who died in 1867.

ABERDEEN HOSPITALS GALA.—A gala in aid of the local hospitals has taken place recently in Aberdeen. The proceedings commenced with a fancy dress cycle parade arranged by the engineering trades in the city. In the Duthie Park there were exhibitions of dancing by the Aberdeen school girls, a display of gymnastics by the boys from Oakland School, and an athletic sports meeting. On the River Dee an aquatic gala was given by the members of the Dee Swimming Club. Unfortunately the weather conditions were very unfavourable throughout. The Aberdeen Hospitals Gala Day Committee intend to carry on their work during the winter. It is proposed to arrange a great whist tournament over all the hospital area, and to organise concerts and other entertainments during the winter months. A flag day will be held on Sept. 10th. Various hospitals in the city have agreed to allow a number of nurses to assist in the collection.

Appointments.

HUNT, J. M., M.B. Glasg., has been appointed Honorary Dean to the Liverpool School of Tropical Medicine.

KENNEDY, W. N. W., M.D. Edin., D.P.H., County Medical Officer, Tuberculosis Officer, School Medical Officer for Selkirkshire, Medical Officer of Health, Burghs of Selkirk and Galashiels, and Medical Superintendent of the Child Welfare Schemes.

ODDY, H. M., M.B., B.Ch. Oxon., M.R.C.P., Medical Registrar to the Westminster Hospital.

TROTTER, G. C., M.D. Edin., D.P.H., F.R.S.E., Medical Officer of Health, Metropolitan Borough of Islington.

Certifying Surgeons under the Factory and Workshop Acts: **FRASER, R. J. L.**, M.B., Ch.B. Glasg., for the Milngavie District of the county of Dumbarton; **POWELL, J.**, M.R.C.S., L.R.C.P. Lond., D.P.H., for the Sennybridge District of the county of Brecon.

Births, Marriages, and Deaths.

BIRTHS.

ACHESON.—On August 15th, at Kenmuir, Ballymena, Co. Antrim, Ireland, the wife of Dr. S. Acheson, of a son.

MARRIAGES.

NELSON—BEAVEN.—On August 12th, at the Parish Church of Withyham in the county of Sussex, Thomas S. Nelson, B.M., M.R.C.S., was married to G. Mary Beaven, M.R.C.S., by the Rev. Henry Carter.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

pathology, and hygiene; Part II. surgery, midwifery, and ophthalmology. 628 medical undergraduates passed examinations in 1920–21. Candidature for the degrees of *B.Hy.*, *M.D.*, *D.Hy.*, or *M.S.* implies that the M.B., B.S. degree has been taken not less than three years (B.Hy., one year) previously.

Grant Medical College, Bombay, was established in 1845, to "impart through a scientific system, the benefit of medical instruction to the Natives of Western India," and recognised by the University in 1860. Attached is a laboratory for scientific medical research. The students are arranged in three classes: (1) graduates and undergraduates of the University of Bombay and other recognised Universities who are educated through the English language for medical degrees; (2) members of the European and domiciled European communities who are educated through the English language for the grade of military assistant surgeon; (3) undergraduates and others for the diplomas of the College of Physicians and Surgeons, Bombay.

University of Calcutta.[13]

For the degree of *M.B.* the preliminary scientific, first, and final M.B. examinations must be passed. The final is divided into two parts, major and minor, which may be taken together. The former includes medicine, surgery, and midwifery; the latter general pathology, medical jurisprudence, and hygiene. An examination for honours is held a week after the pass-list is declared. The fees for the three examinations are Rs.25, Rs.30, and Rs.50 respectively. The *M.D.* degree is granted after examination in medicine, pathology, and mental diseases not less than one year subsequent to the M.B. The fee is Rs.100. Degrees of Master of Surgery (*M.S.*) and Obstetrics (*M.O.*) are also granted. A diploma in public health is granted to possessors of the M.B. degree or L.M.S. diploma by examination after a prescribed course of a year has been carried out. The fee is Rs.100.

Ceylon Medical College, Colombo.

The Ceylon Medical College[14] began in 1870, and the curriculum and examinations were revised in 1901 in conformity to modern requirements. In 1888 the licence in medicine and surgery (*L.M.S.*) granted by the College was recognised by the General Medical Council of the United Kingdom. Lady students were first admitted in 1892. There are two departments in the College—viz., Medical and Apothecary. For admission to the Medical Department of the College candidates must pass Cambridge Senior Local or Senior School Certificate Examination or the London Matriculation Examination in the required subjects. The first professional examination is passed at the end of the first year, the second at the end of the third, the third at the end of the fourth, and the final at the end of the fifth. The fifth year's course includes, besides the usual final subjects, instruction in tropical medicine, skiagraphic demonstrations, and attendance at fever and leper hospitals. The total fees for the medical curriculum, including examination fees, amount to Rs.1423.50. Various scholarships and medals are awarded by Government and private donors.

University of Hong-Kong.

The Faculty of Medicine of the University of Hong-Kong (1912) had its origin in the work of the Hong-Kong College of Medicine founded in 1887. The School of Anatomy was opened in 1913 and special schools for physiology, pathology, and tropical medicine were opened in 1918 and 1919. The University confers the degrees of *M.B.*, *B.S.*, *M.D.*, and *M.S.* The subjects of the first medical examination are physics, chemistry, and biology; of the second, Part I., anatomy, physiology, Part II., general pathology (including bacteriology), and elementary pharmacology; of the third, Part I., surgery and midwifery, Part II., medicine and pathology, including hygiene and tropical medicine. The fee for each subject of each examination is $5, and for conferring the M.B., B.S. $25. The candidate for *M.D.* may present himself in two years and must take general medicine as well as one of the following: State medicine, pathology, midwifery, tropical medicine, physiology. The rules for *M.S.* are similar. The fee for each examination is $100 and for conferring the degree $100. The Registrar of the University is Mr. N. Teesdale Mackintosh, M.A. Oxon.

*University of Lucknow.**

The examination for the degree of *M.B.*, *B.S.* consists of three parts: preliminary scientific, first degree, and final degree. The two latter are held at Lucknow. The preliminary scientific examination in chemistry, physics, and biology is open to candidates who have passed in these subjects at the intermediate examination of the University. The first degree examination comprises anatomy, physiology, and materia medica and pharmacy; it may be taken after two years. The final degree examination comprises two groups: (A) midwifery, hygiene, and medical jurisprudence, taken after two years; (B) medicine, surgery, and pathology, taken a year later. Honours may be obtained in any subject. The *M.D.* and *M.S.* degrees are obtained within not less than one year on passing an examination in medicine and pathology. The fees for the M.B., B.S. examination are Rs.140, for the M.D. and M.S. Rs.£200 each.

King George's Medical College, Lucknow,* prepares students for the medical degrees of the University of Lucknow. The curriculum extends to five college years, each of three terms. Scholarships and bursaries are granted.

University of Madras.

A medical school was established in Madras in 1835, which became the Madras Medical College in 1851 and was affiliated to the University in 1877. The College was originally for supplying assistant surgeons and hospital assistants to the army, but now undertakes also the training of students for the medical degrees and diplomas of Madras University. Candidates for the degrees of *M.B.*, *B.S.* must have passed the Intermediate Examination in Arts of the University or its equivalent, and have studied medicine for not less than five years in a college affiliated to the University. Four examinations are held, the third (at the end of the third year) comprising general pathology and hygiene, and the fourth the other professional subjects. The examination fees are Rs.25, Rs.25, Rs.10, and Rs.50 respectively. The *M.D.* degree may be taken not less than one year after a first-class pass in either medicine, midwifery, pathology, or tropical medicine. The conditions for the *M.S.* degree are similar. The examination fee in each case is Rs.100. A degree in sanitary science (*B.S.Sc.*) can be taken in two parts one year after the M.B., B.S., the total fee being Rs.100.

The Madras Medical College includes a college department, an apothecary department, a chemists' and druggists' department, and a sanitary inspectors' department. The course of training for the M.B., B.S. is charged Rs.120 a year, or a lump sum of Rs.510 if paid in advance. Valuable scholarships are awarded by the Government and by the Dufferin Fund, and special Government stipends to women medical students.

Punjab University.

An examination for the degree of *M.B.*, *B.S.* is held annually in Lahore in May, and consists of three parts —first, second, and final. The first professional examination is open to candidates who not less than two years previously have passed the intermediate

---

[13] The University of Calcutta Regulations and the Calendar are published by the University.

[14] The Registrar of the College is Dr. P. J. Kelly (Dr. L. D. Parsons, Acting Registrar). The Ceylon Medical College Calendar (1919–20) is a volume of 38 pp., published by authority and printed by H. R. Cottle Government printer, Colombo.

* The Medical Faculty of the University of Allahabad has been transferred *en bloc* to the new University of Lucknow, which is awaiting formal recognition of its qualifying examinations by the General Medical Council.

This licence expired at the end of June, 1921, and at the time of his death Mr. Hawker was flying without a licence. In all cases, both for the original grant of a "B" licence and for its renewal, a most careful medical examination is carried out, and it is unlikely that a person suffering from physical defects likely to interfere with his qualifications as a pilot would successfully pass this examination.

Compulsory Vaccination.

Dr. **M'DONALD** asked the Minister of Health if he would at the earliest possible date introduce legislation making it compulsory for all individuals who had been in contact with small-pox cases, and who had not been vaccinated within five years, to submit themselves to vaccination.—Sir A. **MOND** replied: I cannot undertake to introduce legislation for the purpose suggested.

THURSDAY, AUGUST 18TH.

Medical Staff at Chepstow.

Major **PRESCOTT** asked the Minister of Pensions the number of patients at the pensions hospital at Chepstow; the number of medical officers attached to the staff of that hospital; and if any reduction in the number of these medical officers was contemplated.—Mr. **MACPHERSON** replied: The number of patients at present in this hospital is 167. and the staff comprises five medical officers, including the medical superintendent. The hospital is for neurasthenic patients. I am now considering carefully the reduction of the medical staff in this hospital and in others.

Pensioners and Medical Boards.

Mr. **CHARLES WHITE** asked the Minister of Pensions whether he was aware of the many thousands of pensioners whose pensions had been reduced during the present year as a result of special examinations by medical boards; whether any special instructions had been given to medical boards that in the interests of economy examinations should be much more severe than hitherto; and whether he would take such steps as were necessary to bring to the notice of each pensioner the exact method by which he could appeal against the decision of the medical board which reduced or discontinued his pension.—Mr. **MACPHERSON** replied: As I have repeatedly stated no instructions in the direction suggested by my hon. friend have been issued by my Department, and this fact was confirmed most explicitly by the Departmental Committee of Inquiry whose report has recently been published. The fact that during the past twelve months the percentage of cases in which the assessment was unchanged or increased has risen from 52·5 to 61·8 is alone sufficient to refute the suggestion that any such instructions could have been issued. Pensioners are, I am satisfied, fully aware of their rights of appeal and exercise them; and I do not consider that any special steps, such as are suggested in the last part of the question, are called for.

Tuberculosis Patients in Sanatoriums.

Mr. **JOHN GUEST** asked the Minister of Pensions how many ex-Service men suffering from tuberculosis were now in sanatoriums without pension or treatment allowance of any kind; and if he was aware that many of these men were, prior to their war service, strong and healthy, and began that service as A1 men.—Mr. **MACPHERSON** replied: I regret that I am unable to give the information asked for in the first part of the question. I would remind my hon. friend that tuberculosis is a disease which is unhappily prevalent under ordinary civil conditions. The function of the pensions warrant is to compensate for disability due to war service only. If, however, a claim to pension is rejected on the ground that the disability is not of this character, the claimant has a right of appeal to an independent tribunal.

Yorkshire Pensions Administration.

Mr. **LUNN** asked the Minister of Pensions whether his attention had been called to reports of the meeting of the Yorkshire regional advisory council held in Leeds on August 15th, wherein the regional director was reported to have refused members of the council the right to ask questions relating to pensions administration within the area; was he aware that he also refused to place on the agenda important resolutions which had been sent in by members, and that, as a result, the meeting broke up without doing any business; and would he say whether the attitude adopted by the regional director had the approval of the Minister, or could he take steps to see that such pension committees would meet more regularly in the future and deal with any business relating to local pensions administration.—Mr. **MACPHERSON** replied: This matter has just been brought to my notice. I am giving it my personal consideration.

Income Tax and Hospital Subscriptions.

Captain **BOWYER** asked the Chancellor of the Exchequer whether he would consider the possibility of arranging that next year subscriptions to hospitals should not be liable to income tax, in order that by this means the hospitals of the country might once more be placed on a sound financial basis.—Sir R. **HORNE** replied: I regret that I cannot see my way to promise legislative proposals in the direction desired by my hon. and gallant friend.

Opium for Medical Purposes.

Sir J. D. **REES** asked the Lord President of the Council whether the League of Nations was now charged with the duty of deciding how much opium was to be grown in the world and how much was required for medicinal purposes and of preventing the cultivation of the poppy to any greater extent than would suffice to satisfy this need; and, if the answer be in the affirmative, could he say how the League proposed to enforce its decrees in foreign countries such as China and Persia.—Mr. **SHORTT** (Home Secretary) replied: Article 23 of the Treaty of Peace entrusts the League with the general supervision over the execution of the International Opium Convention of 1912, and any conventions on the same subject which may hereafter be concluded. One provision of the existing convention requires the signatories to enact effective laws or regulations for the control of the production and distribution of opium, but it does not rest with the League to decide how much opium is to be grown. The last part of the question, therefore, does not arise.

Foreigners and Lunacy Law.

Mr. **THOMAS GRIFFITHS** asked the Secretary for the Home Department whether the provisions in the Lunacy Acts for the release of an inmate of an asylum applied equally in the case of a Belgian incarcerated in this country, or whether any additional steps were necessary.—Sir A. **MOND**: The provisions for the discharge from the institution are the same in the case of an alien, but where it is proposed to remove an alien lunatic to his native country the procedure to be adopted is laid down in Section 71 of the Lunacy Act, 1890.

FRIDAY, AUGUST 19TH.

Discharge of Asylum Patients.

Mr. **ALFRED DAVIES** asked the Minister of Health whether the decisions of visiting committees re discharge of patients from asylums were subject, in the case of London County Council asylums, to interference or reversal by a central committee sitting in Arundel-street; whether he was aware that medical superintendents had at times exceeded their powers by opening, intercepting, or answering on their own authority applications addressed by relatives to visiting committees; and whether he would take steps to prevent the calling in of a doctor from the Pensions Ministry being used to reinforce, by the threat of the loss of half the patient's allowance, the refusal of a medical superintendent to comply with the next-of-kin's right to the discharge of a service patient under Sections 72–74 of the Lunacy Act.—Sir A. **MOND** replied: I understand that the decisions of London Asylums Sub-Committees with reference to the discharge of patients are not subject to reversal by a central committee, that letters addressed to visiting committees are always laid before them, and that in no case is an application to the committees for discharge dealt with by the medical superintendent. As regards the third part of the question I am informed that no case is known where an incident of the kind referred to has occurred.

St. Andrew's Hospital, Northampton.

Mr. **ROBERT RICHARDSON** asked the Minister of Health (1) whether he was aware that, in answer to repeated inquiries addressed to the Lunacy Board of Control concerning an order issued by a magistrate, William Tomes, on May 8th, 1917, for the reception as a lunatic of a voluntary boarder at St. Andrew's Hospital, Northampton, the Board had stated, in a letter dated August 11th, that they were not in possession of the information required, one item being the date of the above magistrate's death, which they had previously stated to have taken place; (2) whether he was aware that on Feb. 2nd and 9th, 1921, registered letters were addressed to the Board of Control in Lunacy by a sometime voluntary boarder at St. Andrew's Hospital, Northampton, urgently requesting information concerning grave irregularities officially admitted.—Sir A. **MOND** replied: I am informed by the Board of Control that these inquiries relate to matters which are the subject of judicial proceedings which are being taken by the patient in question against the hospital authorities. While proceedings are pending the Board cannot make any statement on questions in regard to which evidence may have to be given at a later stage.

THE President of the French Republic has conferred on Sir A. W. Mayo Robson the Cross of the Legion of Honour in recognition of services rendered to the French Red Cross during the war.

Annotations.

"*Ne quid nimis.*"

THE POSITION OF DENTAL SURGERY.

As all our readers know, the Dentists Act of 1921 s produced profound modifications in the practice dental surgery. The position of the registered ntists is to be altered by a dilution of their body plied by the addition to a register of 4000 of some ,000 names. It is impossible not to sympathise th those who, having undergone professional urses, spent money thereon, and passed standardising aminations, find themselves placed on a level with a dy of men, double their numerical strength, who ve incurred no such expenses and endured no such sts. But while we see the very real grievance of e dentists at present on the register, it was quite possible to leave things dental in the condition ich they had reached, and no other solution than at furnished by the new Act was likely to obtain rliamentary sanction. It was necessary to give a gular status to the body of men upon whom an ormous amount of professional work had necessarily volved, and whose services were in urgent need by e community, having regard to the presence of mpant quackery among us; and we must trust to me and good feeling to right such hardship and nfusion as the constitution of the first new gister may lead to.

The Royal Assent to the Dentists Act, 1921, has been ven, but no registration under its provisions can be fected until some time hence, as the Dental Board, ovided under the Act, is not yet constituted. For e time being, therefore, it is necessary for anyone actising dentistry in this country to be on the isting Dental Register or, of course, on the Medical egister. The regulations for the registration of ental students, and the special courses to be followed r the dental degrees and diplomas at the various niversities and corporations, will be published in HE LANCET at the commencement of the next edical session, by which time, we presume, the new ental Board will be constituted.

DIPLOMAS IN PSYCHOLOGICAL MEDICINE.

DIPLOMAS in Psychological Medicine, though of omparatively recent date, have been instituted at arious centres for some ten years, and affiliation of ental clinics to the teaching in general hospitals, hich has been much recommended, will probably ollow soon. When this takes place there should be o dearth of suitable applicants for posts at asylums, or many young men can then be trained to take up he work in a sympathetic milieu and in scientific pirit. But before the lunacy service can become ttractive, the views of the Board of Control, which ave been stated to the Visiting Committees of sylums, must receive practical expression by a eneral improvement in salaries, in accommodation or married officers, and by the provision in asylums or the more effective treatment upon modern lines f recoverable cases.

The following bodies have now arranged to grant iplomas in psychological medicine or psychiatry—amely, the Universities of Manchester, Leeds, Edinburgh, Cambridge, Durham, and London, and he Royal College of Physicians of London. The regulations for obtaining these diplomas point to much imilarity in the scope of the examinations, though here are differences in the duration of the courses nd the syllabus, details of which can be obtained from the various examining bodies.

The necessity for raising the standard of the training for assistant medical officers in asylums, and of affording facilities for such training, is very real. If the authorities give proper preference to the candidates for vacancies who possess diplomas or degrees in mental disease the status of this branch of the medical profession will be automatically raised, and pay and conditions of service will be made commensurate. There is now a strong feeling within the medical profession, as well as among the public, that the numerous barriers preventing the intelligent treatment of in-patient mental cases should be relaxed. The position of uncertifiable cases requiring mental treatment must be considered, for many of these cases pass from uncertifiable into certifiable, by which time they have become resistant to treatment. But new legislation is required before the treatment of the in-patient mental case can be improved in any broad way, and, in the meantime, the valuable, interesting and humane specialty of psychiatry is not as attractive as it should be to younger men. There is no doubt, however, that the necessary reforms will not be long delayed. The needs for schools of psychiatry have been stated many times during the last few years, notably in the annual report of the Board of Control three years ago, and the deficiencies in the arrangement for the treatment of persons suffering from mental disorder in its early stages are now widely recognised.

EDUCATION OF THE CHILDREN OF R.A.M.C. OFFICERS.

THERE remains in the hands of the War Emergency Fund a certain amount of money, while the applications for grants to enable medical men to restart in practice have mostly been satisfied, some £18,000 having been disbursed in this way. Dr. Newton Pitt, the hon. secretary of the Fund, wrote last week in our columns that those directing the Fund were prepared to turn their eyes in a very practical as well as a very kind direction when employing what money remains at their disposal. For they contemplate assisting in the education of the children of medical officers who have suffered financially through holding temporary commissions in the R.A.M.C. during the war. The Fund is already educating some 25 girls and boys, including several at Epsom, but the intention is to extend this admirable service and to provide subventions in special cases for some who are at medical schools and universities. This will be an admirable movement and one that should appeal especially to medical men who were in good practice before the war, and who may not even now have recovered their status. An educational grant may be of the highest value to parents who cannot be described, or desire to describe themselves, as poor, but who are none the less entirely unable to meet, as they would have been had they not left their practices during the war, the steady drain on income implied to-day by education expenses at our public schools and universities.

THE PREMIER WOMAN'S MEDICAL COLLEGE.

THE *Bulletin* of the Woman's Medical College of Pennsylvania for June is of interest to medical women for it makes the claim that this College, incorporated on March 11th, 1850, as the Female Medical College of Pennsylvania, was the first in the world to be regularly organised for the medical education of women. The College sent out the first woman medical missionary, Dr. Clara Swain, who graduated in 1800, and 121 others of the 1100 alumnæ have since followed her into the foreign mission field. The prospectus in this issue of the *Bulletin* shows that the Woman's College is not resting on its laurels. It has, for instance, the courage to refuse admission to any student who has not had small-pox or been recently vaccinated. The Alumnæ Association offers each year to a graduate of the College a fellowship of the value of $500 for post-graduate study; moreover, there is a trust fund of $5000, out of which loans may be made to students who cannot immediately pay their fees for tuition, which, it may be remarked, amount to $1275 for the four years' course. This is a large outlay for a medical student in America, where before the war less than a third of the actual cost of tuition was

To-day the reverse holds good; the coalminer carries home the colour-bar of his occupation, and no Sherlock Holmes is needed to recognise the cement-maker, the stoker, the cotton operative, the dock labourer, the tanner, or the man from the rolling mills on his way to carry the grime of his work to his artisan dwelling. Example, indeed, is stronger than precept. Not until tidiness, cleanliness, and fresh air, which are the breeding ground of good manners and good thought, are to be found in British industries can we expect to find them in British homes. Here, again, a duty is owed by industry to the community, and a debt the payment of which is long overdue. The community, being largely composed of industrial workers, must benefit by any action which benefits industry, and consideration of the importance of industrial medicine economically to industry must indicate at the same time its economic importance to the community. A few short sums in arithmetic will give help.

LABOUR TURNOVER AND LOST TIME.

A heavy economic burden upon employers and employed has now been recognised in the drift of workers from one place of employment to another. Employers suffer because workers newly engaged experience more accidents and suffer more sickness than the more permanent staff; they are also less productive units. Various estimates have been made of the cost of changing a worker, some place it as high as £5. Let us err on the safe side and put it at £2 10*s*. The worker himself, on changing employment, may be out of work for a while, then, when he does get work, at first he earns less and is more liable to sickness and accidents. He also loses not less than the employers, say £2 10s. on the average. That is to say, every change costs industry not less than £5. Labour turnover in some cases, according to various calculations made in America and in this country, has been placed at 400 per cent. Let us be content to place it at 100 per cent., which means that to maintain a personnel of 1000 workers at full strength every year 1000 workers require to be engaged to replace those who have left. In our factories and workshops alone are some eight million workers; then there are over a million miners with a similar turnover. These, together with those employed on the land, on the railways, and in transport service, as well as shop assistants, clerks, and the mercantile marine, make up not less than 20 million persons. A labour turnover on this total of 100 per cent. at £5 per head comes to 100 million pounds a year. This high labour turnover is unnecessary, as has been shown both in the United States and here; it falls to 30 per cent. where medical supervision of entrants and hygienic conditions of employment exist. This would mean a saving of 70 million pounds a year.

It has been established by careful inquiry that the underlying cause at the back of lost time is either certificated sickness or that condition of lowered health which precedes sickness. Various estimates of lost time have been made. In some cases it amounts to 20 per cent. of total possible hours; but when health conditions are favourable it may fall below 4 per cent. An average of 10 per cent. probably is not excessive for half the employed population; while 4 per cent. may be taken for the other half. Total possible working hours each year may be placed at a round figure of 2000. The loss of 10 per cent. means 200 hours, which at a wage of 1*s*. per hour comes to £10. The loss of 4 per cent. means 80 hours, which comes to £4. Ten million persons at £10 means £100,000,000. Ten millions at £4 means £40,000,000. The difference, £60,000,000, represents what may be easily attained by medical supervision in industry. On these two items alone there is a possible saving of £130,000,000 a year.

INDUSTRIAL CONVALESCENCE.

Another valuable contribution, connected with recovery from sickness, can still be made by industry to the community with benefit to industry itself. Sickness among industrial workers, whether due to accident or ill-health, is liable to be unduly prolonged for two reasons. In the first place, weekly wage earners tend to be unduly anxious about themselves and their symptoms, and unduly anxious lest if their invalidity is prolonged their place may be filled up. This anxiety tends at once to delay recovery and also to induce them to attempt to resume full-time employment before they are ready, when a second breakdown ensues. In the second place, these persons are in receipt of either compensation pay or sickness allowance; both are forfeited directly they start upon work of any kind. Convalescence can be expedited both mentally and physically by graduated activity of an interesting nature, and the best form of interest is remuneration for work done, which is to-day precisely the form of activity prohibited for the industrial convalescent. The result is that to-day enormous sums of money, which there are no means for estimating accurately, are expended in retarding convalescence. Instances of this kind of case can readily be recalled; the poisoned hand or injured limb, cured so far as the surgeon is concerned, for which short-time light employment is needed to restore functional usefulness; the consumptive discharged from sanatorium, but quite unfit to resume full factory hours; the nervous heart case for whom graduated exercise up slopes only gives opportunity for concentrating attention on the vagaries of cardiac behaviour to the detriment of convalescence; the dyspeptic who needs oxygenation resulting from exercise to rectify his gastric peristalsis; the great class of neurasthenias often called debility and suspected to be laziness, which after initial rest urgently need a period of short-time work. The list could easily be lengthened indefinitely. Each and all require—what to-day they cannot get—a period of short-time remunerative activity.

The permanently maimed in industry—to-day cast on to the scrapheap as unemployable, to be a permanent charge on industry or on the rates—still remain for consideration. Holman has estimated that annually 250,000 workers are permanently thrown out of employment through accident or preventable disease in the United States. There are no accurate statistics for this country, but a census taken in Wales in 1918 revealed that one in every 810 civilians had lost one or more limbs, and that in the industrial district of South Wales the proportion was one in every 695. Application of the former figure to the population of the United Kingdom gives a total of limbless civilians at any time of over 58,000. Few persons are ever maimed so that they do not retain some productive capacity. The Ministry of Pensions in this country—and similar evidence is forthcoming from France, America, and other countries—have shown what can be done through industrial re-education for maimed soldiers. Eighty per cent. of war cripples can be trained to carry on a trade without special equipment. The need for continuance of this work for those maimed while earning their livelihood—for assuredly peace has its victims no less than war—is clear. The duty, and also the benefit resulting, lie with industry in whose service the disability is sustained, just as the State has undertaken the duty for those injured in her service.

DEBIT AND CREDIT.

The proposition is put forward that industrial medicine properly applied can effect a saving each year on labour turnover of from 60 to 70 millions, on lost time of 50 to 60 millions, and through industrial convalescence of many millions more. Put the total at £140,000,000 on a conservative estimate. There are to-day something over 40,000 doctors in the kingdom; the cost, if industry employed half the profession and gave each doctor £2000 a year for whole-time work, would amount to £40,000,000 a year, leaving a handsome balance of £100,000,000 a year. Such wholesale engagement of the profession is not proposed, and indeed is not needed. The figures are only instanced to demonstrate that industry by developing industrial medicine has the promise of great profit while it fulfils a great social service.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Parliamentary Adjournment.

PARLIAMENT adjourned on Friday, August 19th, until Oct. 18th on the understanding that if necessity arises the Speaker of the House of Commons and the Lord Chancellor may, after consultation with His Majesty's Government, call the two Houses together within 48 hours in order to deal with an emergency situation. It was originally intended to prorogue Parliament until some date in the late autumn, but in view of the uncertain state of the negotiations in connexion with the settlement of the Irish question the Government have substituted an adjournment to a fixed date so as to avoid the delay connected with the opening of a new session in the event of Parliament being called together at short notice.

HOUSE OF COMMONS.

TUESDAY, AUGUST 16TH.

The Russian Famine.

ON the motion for the second reading of the Consolidated Fund Bill,

Mr. LLOYD GEORGE, in the course of a speech devoted to an examination of the matters which engaged the attention of the Supreme Council of the Allies at its recent meeting in Paris, referred to the Russian famine. He said that he feared that they were faced with the most terrible visitation that had afflicted Europe for centuries. Such news as the Allies had received from Russia pointed to a most appalling catastrophe. The Government had just received a telegram from Mr. Hodgson, their trade representative in Moscow, in which he said that in the districts bordering the Volga, which were normally the richest in Russia, the crops had completely failed, and the crops in the neighbouring districts were barely sufficient to satisfy local needs. His calculation was that 35,000,000 people would require relief. The inhabitants of the famine-stricken districts, seeing that there was no possibility of help reaching them in time to prevent starvation, were moving in large masses in different directions. They had no food-supplies and no shelters, and they appeared to be doomed to annihilation. Of these migratory bodies only some 20 per cent. were able-bodied, and more than 30 per cent. were children, whose condition was piteous. Many of them had been abandoned to their fate by their parents. The people were eating grass, roots, and other rubbish. Continuing, Mr. Lloyd George outlined the measures which were to be taken for relief for immediate suffering. A great appeal was made for food-supplies, particularly milk and flour, and waterproof material for temporary shelters at concentration points, and there was an urgent demand for medical supplies. There was no doubt that this would end in one of the greatest scourges that ever afflicted Europe—pestilence on a gigantic scale. There were not enough doctors as a very considerable number were killed in the war. The Supreme Council had decided to appoint an International Commission to study the possibilities of rendering immediate aid to the starving population in Russia. Great Britain would be represented on that Commission by Sir P. Lloyd-Greame, the Minister for Overseas Trade, Sir John Hewett, a man of great experience in dealing with Indian famines, and Mr. Wardrop, who was Consul in Moscow for some years, and who had a thorough acquaintance with Russia. In Paris there was only one sole desire—namely, how to save these millions of people, and of course how to prevent the spread of the epidemic which would inevitably follow. The best service which the Soviet Government could render at the present moment would be by an act that would at any rate partially restore confidence in countries outside Russia. He did not wish to use the famine as a means of getting recognition of debts that had been incurred. Merely to use the famine for that purpose would be diabolical; but he suggested that because he knew it was the shortest road to relief. There was only one way of getting the goods there and that was by restoring the confidence in the trading community that would make them feel that they could send their goods there without any danger of them being confiscated in the future.

The Bill was read a second time.

WEDNESDAY, AUGUST 17TH.

Army Medical Service.

On the motion for the third reading of the Consolidated Fund Bill,

Lieut.-Col. FREMANTLE directed attention to the medical or health services of the army. He urged the necessity for referring the subject to a Committee of Inquiry. Methods of increasing medical efficiency had been demonstrated in the late war, and he hoped they would be taken into account at any such inquiry as he had suggested. At the present moment they had gone back to the organisation which existed before the war which would result in a lack of coördination and that would last until the time of necessity came again, and a big scandal arose through the inadequate coördination of the different services which together brought the hospitals or the medical units into their proper place at the seat of war. The proposal which was originally vetoed but was afterwards passed—on the recantation of his opinion by Lord Esher—was for some one person on the Army Council to be responsible for the health of the service, and presumably that would be the Director-General of Medical Services. In the second place, an inquiry into the results of the war in this respect should embrace the question of inter-Imperial coördination—i.e., coördination between the medical services of the different Dominions. Thirdly, they required an inquiry into the possibilities of coöperation with the Civil Service both in peace time and on active service. He believed that was being inquired into at the present moment by the War Office, but there was not sufficient actual coöperation with the personnel of the Civil Service even for peace time services. Another suggestion which necessarily required to be considered at the present time with a view to economy was the very large saving which would be possible by obtaining proper coördination between the medical services, now run under 12 different departments of the Crown. As a reduction was necessary in the interests of economy as regarded the Territorial Army, he hoped that the reductions in the medical services should be only pari passu with the reductions on the combatant service. The medical units of the Territorial Army required to be trained, especially nursing orderlies, who did not exist as such in peace times, but had to be trained with a view to being utilised in war. If they were going to make the Territorial Army of any use in war their medical service should be kept efficient, and they must not reduce the medical units out of proportion to the reduction necessary in the combatant units.

The Bill was read a third time.

Tuberculosis Statistics.

Captain ELLIOT asked the Minister of Health the number of beds per 1000 of the population for the treatment of tuberculous patients in 1911 and 1920 respectively.—Sir A. MOND replied: The number of beds in institutions approved by my Department for the treatment of tuberculosis increased from 8888 (or 0·238 bed per 1000 of the population) in August, 1911, to 16,390 (or 0·470 bed per 1000 of the population) in August, 1920.

University Grants in Scotland.

Mr. JOSEPH JOHNSTONE asked the Secretary for Scotland the total Exchequer grant to universities in Scotland for the years 1890, 1900, 1910, and 1920 respectively.—Mr. HILTON YOUNG, Financial Secretary to the Treasury, replied: In the financial year 1890–91 the Exchequer grant was £42,000; in 1900–01, £42,000; in 1910–11, £63,000; in 1919–20, £225,500, of which £165,000 was described as recurrent and £60,500 non-recurrent.

Medical History and Statistics of the War.

Mr. RAFFAN asked the Secretary for War when the medical history and medical statistics of the war referred to by the Under-Secretary on March 10th, 1920, as being in preparation would be ready.—Lieut.-Col. Sir ROBERT SANDERS, Under-Secretary for War, replied: The medical history of the war is being prepared in a series of volumes dealing with the general history of the medical services during the war, the diseases of the war, the surgery of the war, and sanitary work of the war, &c. The first volume of general history is practically ready for publication, and the first volumes of surgery and diseases of the war respectively are practically ready for printing. The medical statistics of the war are being prepared by the Medical War Records Section, which is now under my right hon. friend the Minister of Pensions.

Air Pilots and Physical Defects.

Captain ELLIOT asked the Secretary for Air whether, in view of the coroner's verdict at the inquest held upon the late H. G. Hawker, which attributed the cause of the accident to the physical disability of the deceased and of the long history of tuberculous caries of the spine disclosed by the post-mortem examination, he could state if these physical defects were ascertained at the medical examination at the Air Ministry which took place on Dec. 31st, 1920; and, if not, would he state what further precautions were being taken to prevent the issue of class B pilots' licences to persons suffering from physical defects likely to be prejudicial to the safety of air navigation.—Captain GUEST replied: The fact that Mr. Hawker had had tuberculosis was known at the Air Ministry, but at the examination in December, 1920, in the opinion of the medical officer his state of health warranted the renewal of the licence.

Notification and certification by certifying surgeons is, on the whole, extremely satisfactory. As medical referee for industrial poisoning in the County of London I have a number of cases referred to me in which the certificate of the certifying surgeon is appealed against, and I have rarely found myself in disagreement with the findings of the certifying surgeon. This class of statistics may therefore be regarded as satisfactory.

2. Those arising in industrial processes not certifiable by the certifying surgeon in the district. Such cases are frequently seen by medical men who are unfamiliar with the symptoms of lead poisoning and who rely for diagnosis (not surprisingly) upon the history and occupation of the sufferer who seeks their advice. Further, the opportunities for obtaining knowledge on the differential diagnosis of many types of industrial disease is denied to a large number of men who annually qualify, and who have unfortunately little opportunity at hospital of studying the symptoms of occupational illnesses. This lack of knowledge may at times lead to extravagant and absurd statements, such as that made to the Departmental Committee on lead poisoning amongst painters; a noted physicist, told by his doctor that he had suffered from lead colic, thereupon concluded that the spectroscopic lines seen in drying paint vapour must be volatile lead, and committed himself to that opinion.

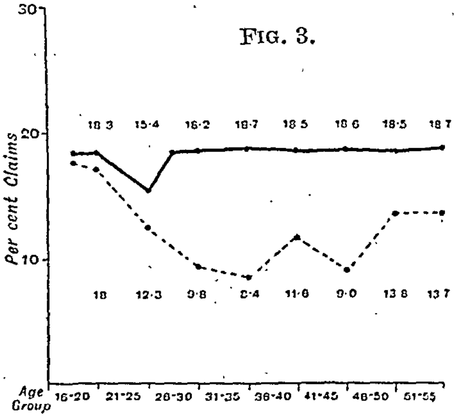
THE HEALTH OF PAINTERS.

The health of painters, the diseases from which they suffer, the processes of their industry that lead to disease, comprise a much-debated problem of industrial medicine at the present time, and I wish to draw attention to some points connected with the question. Complete agreement exists that dry rubbing down of old or new paint may produce lead poisoning and constitutes the painter's main risk. To obviate this risk one school of opinion suggests the total prohibition of lead as a paint. Another class of opinion argues that for one risk that can be easily obviated it is uneconomic to prohibit the use of materials whose manufacture affords occupation to a large class of industrial workers and for which there is no adequate substitute. The whole question, therefore, becomes one of industrial medicine.

Painting is an operation so widely performed that many medical men are acquainted with the curious symptoms following the inhalation of the vapours given off from drying paint. The most delicate tests applied to these vapours fail to show the presence of any lead, yet symptoms closely resembling lead poisoning are produced in susceptible persons, and there is little doubt that a large number of such cases are returned as painter's colic—hence lead poisoning; there is every likelihood that this class of case will increase, as since the war there has been a wholesale tendency to replace turpentine with various other forms of volatile dryers, some of them exceedingly poisonous. The attention of medical practitioners as a whole requires direction towards such forms of poisoning; clinical observation and careful inquiry as to the facts would lead to much useful information.

I have recently had the opportunity of studying the figures of illness suffered by painters belonging to the sickness benefit branch of the Hearts of Oak, and I have taken out the numbers of cases of various types of disease under four headings—respiratory, alimentary, muscular, and nervous. These headings are groups obtained from the short list of the Registrar-General. The respiratory diseases comprise influenza, phthisis, bronchitis, pneumonia, and other diseases of the respiratory organs. The alimentary diseases are colic, diarrhœa, dyspepsia, enteritis, gastro-enteritis, gastric catarrh, gastritis, hæmorrhoids, gastric fever, and gastralgia. Under the heading of muscular diseases I have placed rheumatism and rheumatic fever, myalgia, lumbago, gout, and ague as being likely in the painting trade to be associated together under the general term of "rheumatism." In the nervous division are included neuritis, neurasthenia, neurosis, and vertigo.

FIG. 3.



Sickness benefit in the Hearts of Oak, 1919, showing fewer claims from painters (lower curve) in proportion to general group (upper curve).

From the accompanying table it will be seen that the chief diseases from which the painter suffers are those of the respiratory tract. Now, except in dry rubbing down, the painter is not exposed to the inhalation of dust. The recent admirable paper by Prof. H. E. Armstrong and Mr. C. A. Klein (*Journal of the Royal Society of Arts*, July, 1921) has shown that the droplets of paint splashing are larger than any size likely to be inhaled, and that the amount of actual splashing which reaches the face is minimal and not likely to subject the painter to an intake of more than 0·7 milligramme of lead per working day of eight hours if he is engaged the whole day in stippling, and the high incidence of respiratory disease is possibly associated with the inhalation of vapours of the drying paint. More particularly is this likely to be the case as in the splashing produced in painting a vertical surface practically no splashes come beyond 15 inches from the foot of the wall. Most paint is now sold ready-made, and very little so-called "breaking down" of the dry white lead is done. It is interesting, further, to note that in this group of painters in the Hearts of Oak the actual claims for sickness over the various age-groups is less amongst

IMPORTANCE OF INDUSTRIAL MEDICINE TO THE COMMUNITY.

Papers read at a discussion on this subject held at the Section of Preventive Medicine with Industrial Diseases of the British Medical Association.

I.

By EDGAR LEIGH COLLIS, M.A., M.D. OXON.,

TALBOT PROFESSOR OF PREVENTIVE MEDICINE,
UNIVERSITY OF WALES.

THE stages of scientific progress are represented by thought, then by research resulting in knowledge, and finally by action. Where for any reason, as in the art of medicine, action based on empiricism has come first into existence, new knowledge based on research frequently finds some vested interest opposing action on new lines, or at least some vis inertiæ resulting from innate conservatism. New knowledge in medicine has recently been acquired through research, and practice is gradually changing accordingly. But in no branch is thought, research, and knowledge less hampered by action than in that of industrial medicine, because there is little or no action, and in no branch, possibly for that very reason, has the trend of thought been advancing more rapidly.

MEDICAL SERVICE: CHANGE IN THE OUTLOOK.

During the past 20 years there has been a change in the outlook of medical service. Previously treatment of the sick was the first consideration, and the public only came in contact with the profession in case of illness. Questions affecting the maintenance of health were impersonal and left to the public services concerned with water-supply, drainage, disposal of refuse, and the sale of wholesome food. More recently, however, the personal note has been sounded in relation to maternity and infant welfare, school medical service, tuberculosis, and venereal clinics. Notification of births has provided the information upon which infant welfare work is being constructed. Schools, by gathering together children for educational purposes, provide the opportunity for medical inspection of each child. Notification of tuberculosis again is of value for establishing, through the work of health visitors, personal touch with contacts—the preventive side of the tuberculosis campaign. Here adult life is just touched; but, generally speaking, means have yet to be found for bringing preventive medicine into direct personal contact with the adult. For this purpose industry, which gathers adults together, provides the means. The points for consideration are, whether the community would benefit if industry shouldered this responsibility, and whether industry itself would benefit by such action. The benefit to the community is closely interlocked with the benefit to industry, since the community is composed of constituent groups, among which the industrial group (using the word industrial in its widest sense) forms the greatest part. And if the industrial part of the adult population were sound in health there would not be need for much else.

The state of health of the industrial part of the community is the first thing to be ascertained. Appeal on the matter may be made to different types of data. First come the recent disclosures of the army recruiting examinations. Here only 36 per cent. of the male adults of age to bear arms were classed as Grade 1; but the numbers attaining this standard were found to vary widely according to occupation; the miner and the agriculturist provided a far higher proportion than other groups of industrial workers. Next, appeal may be made to mortality statistics. Here we find the agricultural labourer with a comparative mortality figure of 470; a standard set by the lowly paid and poorly housed agriculturist who works long hours is surely not too high to aim at. Yet the comparative mortality for printers is 773; for tailors, 709; for cotton operatives, 811; for shoemakers, 820; for iron and steel manufacturers, 837; for Lancashire coalminers, 941; for edged toolmakers, 1010; for costermongers, 1507; and for general labourers, 2301. Thirdly, age distribution gives us some information. Out of 1000 occupied agriculturists 225 are aged 55 and over; out of 1000 cotton operatives, 69; out of 1000 printers, 66; out of 1000 coalminers, 75; out of 1000 metal workers, 98; and in the building trades, 121.

None of these sets of data indicates a satisfactory state of affairs, and each brings out marked differences in different occupations. There is, then, a wide field of work before industrial medicine to establish the why and wherefore of these differences. There is an inclination to associate the subject of industrial medicine only with occupational diseases, such as poisoning from lead, mercury, or phosphorus, anthrax, miner's nystagmus, writer's cramp, or caisson disease. These peculiarities of industrial disease are important, both in themselves and in drawing public attention to the influence of occupation upon health. Moreover, through them the guide-post of industrial hygiene has been established—the guide-post which directs attention to prevention rather than to cure. The scope of work has enlarged much beyond the boundaries of occupational disease, but the guide-post is the same. To-day industrial medicine is recognised to be directly aimed at preventing disease and maintaining health. In industry more easily than elsewhere in the community can the balance be cast between the debit of sickness and inefficiency and the credit of health and productivity; this matter will be referred to again later. Here there exists a direct economic interest in maintaining health, an interest which up to the present has hardly been perceived by industry. Nor does the matter end here, for opinion is hardening towards expectation of fulfilment of a definite duty by those who employ labour. The State is now undertaking work upon which large sums of money are being spent in order to bring up from birth to adolescence healthy individuals. Those who thereafter employ these persons have to thank the State that this supply of labour is at their disposal and must in their turn maintain it in health. This opinion finds its expression in Workmen's Compensation Acts and schemes of unemployment benefit. The tendency in the past has been to shift the burden of responsibility on to some insurance agency; but the latest compensation scheme under the Workmen's Compensation (Silicosis) Act, 1918, places upon industry—the refractories industry in this case—the responsibility of shouldering its own insurance. Action on these lines will probably prove a direct incentive to industry to lighten the liability by actively pursuing preventive measures.

THE PERSONAL NOTE.

Allusion has already been made to the personal note in the application of modern preventive medicine. This note is not to be perceived to-day in factory life. Yet the community as a whole needs it. The State up to adolescent life is striving to instil the principles of health, and its efforts are yearly increasing in effectiveness. Then the youth passes into some occupation where his master, as judged by social standing and worldly wealth stands far above the school teacher, and is presumably more worthy of respect. But now the youth finds no attention paid to health and its maintenance. Is it a matter for surprise that he disregards the precepts of his former teachers as something only concerned with boyhood, something not needed in manhood, something it is manly to despise? There are here immense possibilities in industry. Fresh air, sunlight, cleanliness, and wholesome food are necessary to efficiency in the work of adults just as they are for children. Moreover, a standard set in these matters by the all-admired capitalist who rules industry would spread from the factory to the home.

cases, after subsidence of the acute symptoms, there persisted insomnia, restlessness, and definite mental changes which showed themselves in various degrees of moral obliquity. The nocturnal restlessness and diurnal somnolence which may follow encephalitis in children has received considerable attention. Roasenda,[9] Morley Fletcher,[10] and Findlay and Shiskin[11] have described such cases. But in these there was ultimate improvement and recovery; the condition appears to be a manifestation occurring in the stage of recovery from the acute symptoms, and not a permanent sequel. One of the most striking of the after-results of the disease is the condition of symptomatic paralysis agitans. Farquhar Buzzard and Greenfield[12] have described the condition in an adult; and Kinnier Wilson[13] has reported two cases, in which the resemblance to a case of Parkinson's disease was persisting 12 and 15 months after the acute stage of encephalitis. We have included in our series a similar case in a boy of 8 years.

Results in 25 Cases of Encephalitis.

In our investigations we have not concerned ourselves with the questions of the symptomatology or the pathogenesis of the disease. We have chosen 25 cases between the ages of 3 months and 11 years, in which the diagnosis of epidemic encephalitis appeared to be straightforward and incontrovertible. Each case was closely observed as an in-patient, either in the Hospital for Sick Children, Great Ormond-street, or in the children's ward, St. Thomas's Hospital. The diagnosis was reached, in each instance, only after examinations of the cerebro-spinal fluid had been made and the Wassermann reactions of the blood and cerebro-spinal fluid obtained. In each case the ultimate course of the disease was such as to confirm the diagnosis against the possible mistake of having included such conditions as brain tumour or brain abscess. And finally, in order that a proper estimate of the effect of the disease might be attempted, we have included as cases only those children who, before the onset of the illness, were of normal health and intelligence.

Mortality Results.

Of our 25 cases only one was fatal. This was a girl aged 1 year and 9 months. The onset of the illness in this case was sudden, with fever, delirium, and convulsive twitchings; coma ensued, and continued until death on the seventh day of the illness. The diagnosis was confirmed at a post-mortem examination. In comparison with the figures of other observers who have investigated the disease in adults a mortality of 1 in 25 must be considered a low rate. Economo[14] and Netter[15] have estimated the mortality in cases they have seen at 40 per cent. and 30 per cent. It would appear that in children the immediate mortality is less. In Findlay and Shiskin's series of 24 cases in children under 16 years of age two died.

The Effect of the Illness on Surviving Cases.

Of our cases, 24 survived the initial illness and are still alive. In the table of results are given brief descriptions of their present condition, based on recent clinical examination of the patients and on evidence of the mental condition given by parents and friends. In 6 of these children a complete recovery has resulted. They are as bright, intelligent, and active as normal children of their age; no sign of the illness remains. The remaining 18 children all show definite affections directly attributable to the original attack of encephalitis. These affections are so varied that some attempt at their classification is advisable.

Effect on Mental Condition.

The most apparent results are to be seen in the present mental condition of the children. Of the 18 cases affected, 7 are grossly mentally deficient and 11 show minor degrees of mental deficiency.

The seven grossly mentally deficient cases appear to be in a state of permanent and hopeless idiocy. Unintelligible, unable to recognise even their parents, grimacing and drooling from their lips, they present the typical picture of an idiot child, with all its abnormal gestures and actions. The eldest is now 7 years of age and is an inmate of a mental hospital; the remainder are probably destined to a similar existence. Two of these cases (Nos. 8 and 11 in the table of results) are, moreover, in a condition of spastic diplegia with "scissor legs" and contractures.

The second group of 11 cases includes those children in whom slighter degrees of mental deficiency—mere dulling of the intellect, or abnormal psychical symptoms—have resulted. In all of these the mental changes are greater than could be accounted for by the long period of ill-health, with its lack of teaching or other mental stimulus, through which they passed. They date from the illness itself, and must depend upon the organic changes resulting from the acute inflammatory affection of the brain substance. The worst cases, though able to recognise their parents and other familiar objects, are yet too dull to learn a simple lesson. The probability is that with training they will develop sufficient intellect to preserve themselves from danger, but will be incapable of earning their own livings, and will thus be classified as imbeciles in the usual meaning of the term. Others of this group we have classified as being slightly mentally deficient. Their parents usually describe these as dull and backward since their illness. We have also included in this group four important cases (Nos. 16, 17, 22, and 25 in the table of results) with a medico-legal interest. These children were normal before being affected by encephalitis lethargica. Since their illness they have regained their capacity for lessons, but definite affection and alteration of the moral sense has resulted. They are mischievous and untrustworthy, and some phrase such as "altered habits" is used by their parents to describe the change. One of these is so marked a case of moral imbecility, resulting from encephalitis, as to deserve a more particular description.

No. 25, in February, 1918, then aged 11 years, had encephalitis lethargica with confusion, stupor, and lethargy for five weeks. There was slight rigidity of the limbs and tremor of the hands during the stage of recovery. This case was described by Dr. Batten and Dr. Still in their paper on Epidemic Stupor. The boy appeared to make a complete recovery and was discharged from hospital. He was next seen by us in 1921, being then 14 years old. His mother, who has six other children, was emphatic in her description of the change the illness had wrought in the boy's character. Previously he had been a normal, intelligent, and docile child. Since his illness he has shown uncontrollable criminal tendencies. He has been convicted for theft on several occasions, and is regarded by the police as an incorrigible thief. His intelligence does not appear to be impaired. He could remember the name of the physician under whose care he was three years ago.

Another case, No. 22, has been similarly affected. Since recovery from his illness he has shown mischievous uncontrollable tendencies. It has been found necessary to remove him to an industrial school, in an attempt to check the moral changes which are showing themselves.

Effect on Physical Condition.

The children are all well nourished. They have preserved the ability to gain weight and thrive. Those who are grossly mentally deficient show that delay in the acquisition of normal actions usually seen in such children. They reach the age of 18 months to 2 years before they can sit up. The power of standing and walking is delayed in a like manner. In these cases the physical condition is a result of the mental backwardness and not due to organic paralyses. In seven of the cases there are, however, organic residual paralyses which have persisted since the original illness. Two of these (Nos. 8 and 11), now aged 2½ and 5½ years, are typical examples of spastic diplegia. With "scissor leg" gaits, spastic legs, and extensor plantar responses, they present a clinical picture indistinguishable from those cases of spastic diplegia usually ascribed to prenatal cerebral damage and birth injury. In one case (No. 24) the hemiplegia, which arose during the acute stage of the encephalitis, *The trend of thought to-day is against nationalisation of industries, but industries must realise that while maintaining their independence they take over at the same time certain responsibilities as regards those employed which under nationalisation would be undertaken by the State.* Recognition of these responsibilities and taking them up would entrench the position of industrial independence. Failure *in this matter, quite apart from economic waste,* must sooner or later cause those employed to demand reconstruction of modern industrial organisation. Such reconstruction might seriously dislocate the community with sufferings as a consequence such as Russia is *now experiencing, with no commensurate* advantage. To-day our profession stands too much aloof from such thoughts, and does not do enough to impress upon industry that there is a science of medical sociology the principles of which, if applied to labour unrest, would give results more certain, more sure, and more enduring than all the remedies evolved from the inner consciousness of political economists who may know somewhat of politics but know nothing of the economies of the human machine, and who give *lip service only to the truth that a* healthy body is necessary for a healthy mind. In very truth the community to-day greatly needs an *industrial medical service; it needs it in the interests* of health; it needs it in the interests of economy; it needs it in the interests of industrial efficiency; *it needs it in the interests of social contentment.*

II.

BY SIR KENNETH GOADBY, K.B.E., M.R.C.S., D.P.H. CANTAB.,

REFEREE FOR INDUSTRIAL POISONING, HOME OFFICE, LONDON DISTRICT.

DURING inquiry into the causes of the disabilities suffered in many industrial processes, more especially those in which lead is used or manufactured, one is constantly hampered by the perfectly frank and often good-willed obstruction offered by both employer and employee to innovations directed towards the improvement of health conditions. On the other hand, extreme measures may be proposed to combat an evil recognised by its effects, though its actual cause may be little understood, and the somewhat tempting but unscientific and uneconomical attitude expressed in the phrase, "I cannot away with it," is easily adopted. An instance of this no doubt perfectly genuine but misguided frame of mind is to be found in the controversy at present *raging* regarding the suggested prohibition of the use of white lead as a pigment in the arts and manufactures. It is well known that lead poisoning exists amongst the users of lead, and that its incidence has diminished, following the reduction of lead dust in dangerous lead processes; yet in *an extraordinary* document bearing evidence of the hand of the acute propagandist —the so-called questionnaire emanating from the *International Labour* Bureau at Geneva—dust as a cause of poisoning in the painting trade is dismissed with an almost contemptuous negative. Reference has only to be made to the excellent results obtained through the special Home Office rules in the white lead manufacture, in potteries, and in other trades—in the administrative application of which rules Prof. Collis had no small share—to see the fallacy of disregarding dust as the most important vehicle by which lead poisoning in industry is produced. In these industries the use of the deleterious material is still continued with comparative safety in processes in which it has been possible to reduce the amount of dust produced within innocuous limits; the quantity of soluble lead in pottery glaze has been reduced, but it is essential to point out that the glaze is still obtained by means of lead silicate, although the application is modified, in that the fritting or combining of the lead with the silica is carried out before the glaze is applied to the ware, in lieu of the formation of the lead silicate from a soluble salt of lead during the *process of firing the ware;* it is therefore not fair to argue from the diminution of the quantity of soluble lead present in a glaze that there is a diminution in the quantity of soluble lead present in a paint. This by the way. Prof. Collis has emphasised the necessity of the industrial individual acquiring a competent knowledge of the danger of any deleterious process in which he is engaged, and I would further add that as in microbic disease individual susceptibility varies within wide limits, so also the resistance towards varieties of industrial poisoning shows wide variations of tolerance and intolerance.

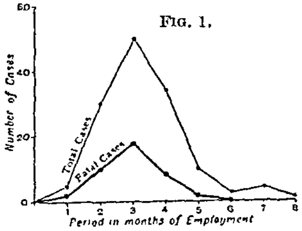
LEAD POISONING.

Prof. Collis has shown a curve (Fig. 1) demonstrating the presence of susceptibility and immunity towards T.N.T. (*Journal of the Royal Society of Medicine,* 1916), and in a recent paper (Royal Society of Arts, June, 1921) I was able to show that the largest incidence of lead absorption amongst workers in white lead factories occurs within the first six months of their exposure, and that by careful supervision, alteration of employment and suitable treatment, such susceptible persons *finally obtain a tolerance* which enables them to work over long periods without disability (Fig. 2). This important factor is well brought out by Prof. Collis's suggestion of a period of industrial convalescence for persons who have suffered from any type of *industrial disease;* at present the factory surgeon is often handicapped by the absence of facilities to carry out such procedure. Lead poisoning bulks largely as an industrial disease, but its statistics are sometimes regarded with some degree of suspicion, particularly as regards those trades in which lead poisoning is not a certifiable disease, and in which no special rules or medical *inspection* is extant. The statistics of lead poisoning may thus be divided into two categories:—

1. Those in which the case is seen by a certifying surgeon—a surgeon appointed with a special knowledge of the symptoms of the disease, and practising in the particular district in which the diseases are likely *to occur.* I regard the suggestion that the certifying surgeon should be superseded by a whole-time official *as not in* the highest interests of the working class population. A surgeon practising in a district is better *acquainted with the* general run of disease in that district than a whole-time officer not engaged in private practice, who has not the same *opportunity to estimate* the value of certain symptoms common to both lead poisoning and other diseases.

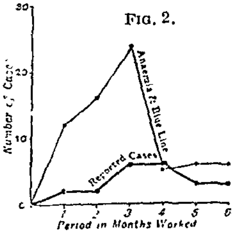
T.N.T. Poisoning.

FIG. 1.



Susceptibility *and Immunity.* Time of onset and fatal cases according to number of months worked (after Collis).

FIG. 2.



Final development of tolerance. Extracted from factory medical registers, *1911–1921.* Upper curve shows number exhibiting signs of absorption without definite symptoms of poisoning.

EFFECT OF CULTURE-MEDIA UPON AGGLUTINATION OF MENINGOCOCCI.

By I. WALKER HALL, M.D. VICT.,
PROFESSOR OF PATHOLOGY AND BACTERIOLOGY, UNIVERSITY OF BRISTOL;
AND
G. E. TILSLEY, M.R.C.S., L.R.C.P. LOND.,
FORMERLY DEMONSTRATOR OF PATHOLOGY, UNIVERSITY OF BRISTOL.

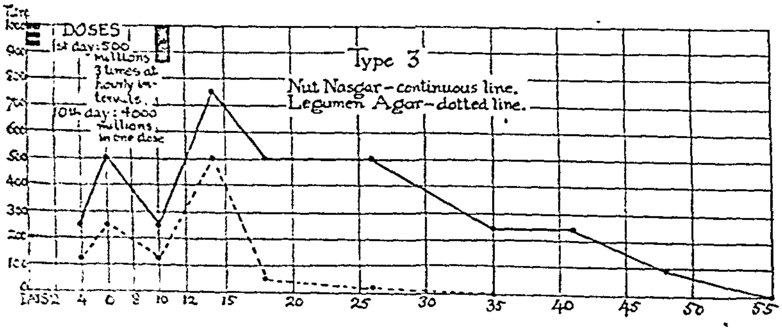
(*From the Pathological Department of the University of Bristol.*)

VARIATIONS in the rapidity of growth and size of colonies, or delayed appearances of typical characteristics due to the use of media differing in constitution or methods of preparation, are well known. That the antigenic and agglutinative features might also be altered was suggested during some of our previous work.[1, 2, 6] Victorson has shown that *B. paratyphosus B* shows differences in agglutinability when grown upon blood agar, Löffler's serum, dextrose broth, lactose broth, or potato.[8] Michaelis observed that the strain known as *X 19* was influenced in its agglutination titre by the nutrient media selected for its isolation and subculture.[11]

The present communication is concerned with the growth of meningococci upon varying media, especially with regard to the preparation of emulsions for the purpose of typing the several strains. The technique has been modelled as far as possible upon the criteria demanded by Tulloch.[6]

The material for the investigation was obtained from local cases examined during the epidemic of 1916. After isolation and type identification of the meningococcus, an aliquot portion of a counted emulsion of each strain was sown on plates containing equal volumes of warm 20 and 40 amino-acid nut nasgar, nut nasgar with buffer salts or ascitic glucose fluid, and legumen agar with, and without, the addition of blood. All the types of media were titrated to pH 7·6. After 24 hours' growth the colonies were emulsified in freshly prepared normal saline in distilled water, and then heated to 65° C. for 20 minutes. Two c.cm. of 5 per cent. pure phenol were then added for each 20 c.cm., and the whole emulsion standardised to contain 2000 meningococci per c.cm. The emulsions were transferred to sterile corked bottles.

CHART B.

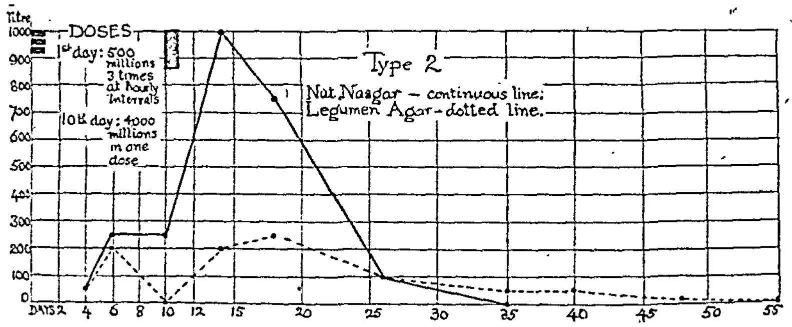


Owing to the pressure of war work, it was not possible at that time to make more than a few preliminary estimations. The numerous emulsions were stored in the dark, at room temperature, until the end of 1919, and in the ice-chest thereafter. In February, 1921, they were tested for sterility; no organisms were found in films other than meningococci, and cultures were sterile. When opportunity permitted, it was considered worth while to continue the original intention, in order to determine whether the agglutinability of the emulsions was altered by the long period of storage, and whether the agglutinogenetic capacities of the bacterial protein had been retained.

The "nut nasgar" differed from ordinary nasgar by the inclusion of pea-nut constituents, according to the suggestion of Mackenzie Wallis.[4] The pea-nuts were ground into a coarse powder, and kept in an airtight bottle. As the pea-nuts exposed for sale are derived from varying sources, we found it necessary to determine which varieties were best for the purpose, and what constituent of the nut acted as a stimulant to bacterial growth. The inquiry is still in hand. For the work now described, the same sample of nuts was available throughout. The preparation was as follows:—

A.		B.	
Pea-nut powder ..	10 g.	Lait-proto broth[2]	300 c.cm.
Hydrocele or ascitic fluid ..	100 c.cm.	Distilled water ..	300 c.cm.
Distilled water ..	200 c.cm.	Agar-agar	20 g.
		NaCl	3 g.

CHART A.



Boil B until agar melts, and A for 15 minutes, both in steamer. Cool both to 50° C. Add A to B, and add white of one egg. Autoclave and filter. Adjust amino-acid content to 20 or 40.[3] The lait-proto broth was previously adjusted to pH 8·0, and the final product made up to pH 7·6 with N/10 HCl.

The pea nasgar (or legumen agar) was prepared in accordance with the details given in the Medical Research Committee's report on Cerebro-Spinal Fever, 1916, and adjusted to pH 7·6 and 21 amino-acid content.

Agglutinability.

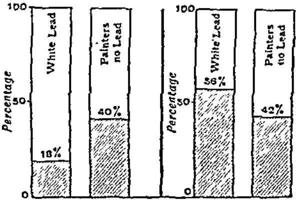
Each strain of meningococci was grown upon six media of differing composition. An emulsion was prepared from a 24-hours' growth. Finally, it was subjected to the action of standard type serums, kindly provided by Major J. Bell, R.A.M.C. Lab., Millbank, and set up with the usual controls. The results are stated in Table I. The standard sera were made up to a titre of 1000 for each type, so that the dilutions of each are comparable. The difference between the agglutinability of cocci grown on nut and pea nasgars is quite striking, but neither the amino-acid content nor the addition of buffer salts or glucose effects any change. The reduction of the original broth to 20 per cent. amino-acid content is quite compatible with good growth and agglutinability.

The two types of meningococci show similar differences with regard to the culture media, and the several strains exhibit a uniformity in titre. The painters than that of the total number of persons claiming benefit. (Fig. 3.) The absence of high incidence of disease of a type which might be attributable to lead—namely, those in the alimentary and nervous sections—together with the high incidence in the respiratory type, is a little difficult to reconcile with the supposedly high incidence of lead poisoning amongst painters as a whole, as it would seem that if lead poisoning were a serious feature in the painting trade it should show in a block of figures of this type.

WHITE LEAD WORKERS.

There is, therefore, an issue between these two points of view, and the community is entitled to inquire of exponents of industrial medicine the proper solution of such a dilemma. Recent work has to some extent suggested the direction in which this may be sought. Comparison of the disease occurring in white lead workers who work in lead alone, uncomplicated by the dust of angular particles, shows that while respiratory diseases are common in potters, who inhale flint dust and lead together, it is not so common amongst white lead workers who only inhale lead dust. The material of which the painter makes use is soft and not angular, and it is well known that persons exposed to baryta and other types of dust without angular particles do not show a high incidence of respiratory disease. The painter, on the other hand, is exposed to a risk to which neither of the other classes is exposed—namely, the inhalation of fumes of volatile products (turpentine and turpentine substitutes) which are known to produce respiratory effects in susceptible animals. In a recent examination of white lead workers and painters the average blood pressure of the painters in the same age-groups was found to be higher than that of lead workers. (Fig. 4.) This is a suggestive point; the constant inhalation of vapours of volatile fluids, among which are compounds of the benzine and paraffin series, is conducive to renal affection and high arterial tension. The higher arterial tension of painters is the more striking in that painter's work is much less severe, less muscular effort being required in using a paint brush than in carrying half-hundredweights of lead or huge baskets filled with wet tan.

FIG. 4.



B.P. above normal. | B.P. below normal.

Percentage of white lead workers and painters not using lead paint which shows blood pressures above and below normal for age 20–60.

One further statistical fact, culled from the 1911 figures of the Registrar-General's report, appears to corroborate the growing opinion that it is in the volatile portions of the paint rather than in its solid constituents that one must look for the cause of the disease. The birth-rate tables per 1000 males aged under 55 years gives a birth-rate per 1000 for the painters as 155, being actually higher than that of clergymen, barristers, solicitors, law clerks, farmers, and graziers (148), whilst the figure for all males is 162; such figures do not suggest severe lead absorption.

This short epitome of some of the facts of the painting trade controversy supports by a specific instance the difficulties underlying the problems of occupational disease outlined by the opener of the discussion, and emphasises the necessity of strictly scientific methods in dealing with problems of industrial medicine.

THE AFTER-EFFECTS OF EPIDEMIC ENCEPHALITIS IN CHILDREN.

BY DONALD PATERSON, M.B., B.CH. EDIN., M.R.C.P. LOND.,
MEDICAL REGISTRAR, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET;
AND
J. C. SPENCE, M.C., M.D. DURH., M.R.C.P. LOND.,
JOHN AND TEMPLE RESEARCH FELLOW, CHILDREN'S DEPARTMENT, ST. THOMAS'S HOSPITAL.

THE investigation, which forms the subject of this paper, was undertaken for the purpose of inquiry into the subsequent fate of such cases of epidemic encephalitis in children as had come under our notice in hospital during the early stages of the disease. It arose from a realisation of the difficulty in offering an accurate prognosis in this disease, and in answering the question, which invariably arose, as to what chance of complete recovery on the one hand, or of mental and physical impairment on the other, might be expected to follow it. This question was apparently present in the minds of those observers who, in the early days of the recent epidemic, were describing the disease. MacNalty,[1] in the Local Government Board report on Encephalitis Lethargica (1918), warned his readers that until more evidence was available a guarded opinion should be expressed as to the risks of after-effects in this disease, especially in regard to possible mental changes and persistence of residual paralyses. Farquhar Buzzard,[2] writing at the same time, was more certain that such results might be expected. "I am convinced," he wrote, "that a large number of cases of epilepsy, of mental deficiency, of hemiplegia, and of diplegia are the permanent results of attacks of encephalitis in childhood."

In spite of the widespread prevalence of the disease, this aspect of the problem has received comparatively little attention in the abundant literature which has grown up round the subject. It would have been useful had any record been made of the ultimate fate of those cases of encephalitis which occurred in the epidemics of the disease prevalent in Northern Italy in 1890, and in Germany in 1892. But we have been unable to trace any such record. Leichtenstern,[3] Nauwerck,[4] and others who investigated these cases confined themselves to a study of the symptomatology and pathology of the disease; and Chartier,[5] in a full review of the literature of the subject of acute encephalitis in 1907, provided no evidence of after-effects which may follow the disease.

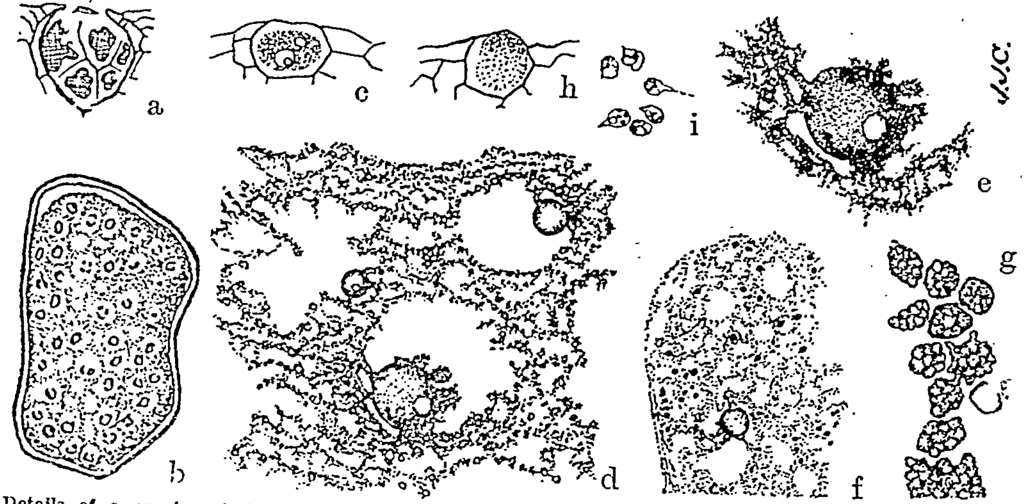
Permanent Disabilities.

More recent publications have indicated, however, that we may expect to find various degrees of permanent disability in many of the patients who have been affected during the past few years. Batten and Still's[6] original paper on "Epidemic Stupor" in children contains no reference to these sequels of the disease; but since we have had an opportunity of re-examining three of the four cases therein described, we can supplement this record. These are included in our series of cases, and it will suffice for the moment to say that each of them has been permanently affected. One, quite mentally deficient and incapable of recognising even her own parents, is now an inmate of a mental hospital; the second has become a dull, backward, and slow-witted child; the third, since recovery from his illness, has shown a strange alteration in habits and character; he is now an incorrigible kleptomaniac, and has spent most of the period since recovery under detention for theft.

Cruchet[7] has contributed valuable observations on the results of encephalitis lethargica in 32 cases. Of these, 12 were directly fatal. The remainder were all affected in some way, showing either the paralysis agitans syndrome, perverse irregular movements, or some degree of mental deficiency. Francioni[8] has recently published 20 cases illustrating a post-encephalitic syndrome in children. In these state in a chronic syphilitic lesion as shown in "Protozoa and Disease," Part II., Fig. 18.

Last year the conclusive settlement of a biological question was made public by K. M. Curtis,[4] who has found that the zoospores of a *Synchytrium* conjugate in pairs, the zygotes so formed alone being capable of developing into resting cells. C. Lundie and F. H. Goss have described observations[5] on bodies seen by dark-ground illumination in syphilis. Their Figs. 8, 9, and 10 of a bi-flagellate organism are probably of zygotes, which might have become spirochætes in favouring surroundings. The uniflagellate bodies described by several observers are probably the zoospores, Schaudin's bi-flagellate spirochæte (1905) being the zygote of the parasite which causes syphilis. Curtis does not mention multiplicative fission of zygotes of *S. endobioticum*, but it has been described in the Rhizomastigina, a group of protozoa which have affinities with the Mycetozoa.

FIG. 1.



Details of a species of *Synchytrium* in a thistle-leaf. *a*, sorus subdivided into sporangia; *b*, a sora sporangium, zoospores nearly formed; *c*, early stage of direct sporangium; *d*, part of *c* more magnified showing three nucleoli; *e*, a single nucleolus still more magnified; *f*, a stage later than *d*, a single nucleolus and grains of chromatin in a finely granular plasm; *g*, a stage later than *f*, protoplasm segmented prior to zoospore-formation; *h*, direct sporangium; *i*, part of *h* more magnified, zoospores. Magnification: *a*, *c*, and *h*, × 80; *b*, *d*, *f*, *g*, and *i*, × 1000; *e*, × 1500.

In view of spirochæte-like forms having been described in infective sarcoma of dogs by Mettam, in cancer of mice by Gaylord, in vaccine vesicles by Bonhoff, and in mammary sarcoma and in chorio-carcinoma by myself, it will be seen that a wide field for investigation is opened.

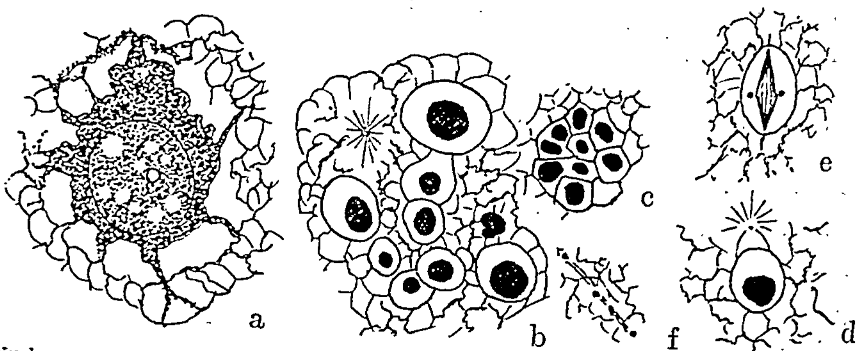
To look again at the nucleolus of the *Synchytrium* in the thistle (Fig. 1 (*e*)), from being composed of uniformly dense refracting material, to which Van Beneden's term plasson*[6] may be applied, it has pushed out buds with granules at their surface, which stain purple with hæmatoxylin. Some of the buds are continuous with the cytoplasmic net composed of linked stellate elements, like those of a mycetozoan plasmodium. The nuclear cavities are sap-vacuoles, and the nucleoli may be called metroplasts, the mother plasson.

Looking at Fig. 1 (*f*) it is seen that the plasmodium has changed, being finely granular with definite points of chromatin; from plasson it has become a chromidium. It might be supposed that the points of chromatin would become the nuclei of the zoospores, but, instead, the plasmodium would appear to change again, becoming coarsely granular, the granules staining purple; then to subdivide into rounded segments, in which the nuclei of the zoospores appear and, with much reduction in size, the segments become zoospores. These variations of form in a parasite are easy to recognise in the thistle with its simple cellular structure; in human tissues with a variety of cells it is not always so easy.

"*Plassomyxineæ.*"

In 1892 a similar succession of changes was described by myself in bodies in a squamous-celled cancer, and later in various cancers and sarcomas, in a secondary syphilitic lesion, in the vaccinated cornea, and in some other pathological conditions. Touching their biological position all that I could say was that they were of the same nature as Cobbold's psorosperms. I have never thought them to be Coccidia. I can now see that the bodies referred to are of the same class of organisms as this Synchytrian of a thistle. There are some points of difference, and the parasites which, with others, I have described in human and some animal diseases constitute a group

FIG. 2.



Nuclear processes in *Synchytrium decipiens*. *a*, large irregular nucleus without membrane, but with a large nucleolus; *b*, group of bird's-eye nuclear bodies with an aster; *c*, cluster of bird's-eye bodies such as are often seen in cancer; *d*, bird's-eye body with aster attached; *e*, mitosis, metaphase; *f*, mitosis anaphase. After F. L. Stevens.

---

[*] This condensed nucleolus-like form may be distinguished by the qualification *pycno* in contrast to the extended or plasmodial form, which may be called *chasmatoplasson*.

Table of Results.

No. of case.	Age in years at onset of attack.	Character of illness.	Present condition of patient.
1	3/12	Severe case; S. 6 wk.: oph.; slow recy.	Now 2 6/12 yr.; unable to sit up or talk; idiot; perverse movements.
2	4/12	Severe case; S. and convulsive twitchings 4 wk.: slow recy., appearance spastic rigidity limbs.	Now 1 6/12 yr.: idiot; continually screaming, unable to sit up or recognise parents.
3	11/12	L., difficult to rouse for 1 wk.; ptosis.	Now 4 6/12 yr.; complete recy.
4	11/12	L.S. 6 wk.; oph.	Now 3 yr.; idiot; unable to talk or recognise parents; perverse movements.
5	11/12	L.S. 6 wk.; oph.	Now 2 8/12 yr.; idiot; unable to sit up, talk, or recognise parents.
6	1 1/12	L.S. 6 wk.	Now 2 7/12 yr.; mentally deficient; can recognise parents and say few simple words; cannot sit up, purposeless movements with limbs.
7	1 3/12	Sudden onset; convulsions, then S. 3 wk.	Now 4 11/12 yr.; mentally deficient; unable to walk; can recognise parents; purposeless movements with limbs.
8	1 3/12	Slow onset; L.S. 2 mth.; oph.	Now 2 6/12 yr.; typical picture of spastic diplegia; idiot; scissor legs and oph.
9	1 8/12	Sudden onset; unconscious, fits, hemiplegia; rapid recy.	Now 2 2/12 yr.; complete recy.
10	1 9/12	Sudden onset, fever, delirium, convulsions.	Death on 7th day of illness; diagnosis confirmed at P.M.
11	2 6/12	L.S. 4 wk.; oph.; rigidity of limbs on recy. from stupor.	Now 5 6/12 yr.; idiot; spastic diplegia: scissor gait; cannot speak.
12	2 10/12	Convulsions, L.S.	Now 5 1/12 yr.; mentally deficient: clean in habits; can say few words; knows his name, unable to walk; purposeless movements of limbs.
13	4	L.S. 4 wk.; oph.	Now 7 yr.; idiot; in mental hospital; unable to recognise his parents; rigidity of arms and legs, with purposeless movements.
14	4	L.S. 3 wk.; oph.; rapid improvement.	Now 4 6/12 yr.; complete recy.
15	5	L.S. 3 wk.; *ataxia of arms on recy.*	Now 6 6/12 yr.; complete recy.
16	5	L.S. 6 wk.; oph.	Now 6 yr.; good recy.; intelligence normal; restless, irritable, and altered in habits.
17	5	Fever, L.S. 4 wk.; oph.; slow recy., followed by ataxia.	Now 8 yr.; slightly affected; dull and backward, attends special school for mentally deficient.
18	6	Gradual onset; L.S. 4 wk.; oph.	Now 9 yr.; mentally backward, untrustworthy, emotional; otherwise normal.
19	6	S. 3 wk.; recy., with marked ataxia of arms and legs.	Now 7 yr.; complete mental recy., but still slight ataxia in gait.
20	6	Sudden onset with delirium; unconscious 2 wk.; hemiplegia and convulsions, rapid recy.	Now 8 yr.; attends school for mentally deficient; dull and backward, no paralysis; sleep-walker.
21	7	Sudden onset; severe *choreiform type.*	Now 8 yr.; symptomatic paralysis agitans syndrome; fixed attitude, mask-like face, pill-rolling movements of fingers; mentally backward.
22	9	Gradual onset; L.S. 4 wk.; oph.	Now 12 yr.; dull, mentally backward; ataxia of left arm; character altered; now in an industrial school.
23	9	L.S. 1 wk.; oph.; delusions during stage of recy.	Now 12 yr.: complete recy.
24	10	L.S., hemiplegia.	Now 12 yr.; mentally backward, right hemiplegia: contractures persist.
25	11	*Confusion and stupor* 5 wk.; slow recy.	Now 14 yr.; altered habits; kleptomaniac: good physical recy.

Oph., ophthalmoplegia. Recy., recovery. L., lethargy. S., stupor.

has persisted, and contractures have resulted. Three cases (Nos. 17, 19, and 22) have residual ataxia and incoördination of the arms, without any sign of an organic pyramidal lesion. In one case (No. 21) the symptomatic paralysis agitans syndrome has resulted. The boy is now 8 years old. The original encephalitis occurred 15 months ago, and was of severe "choreiform" type. On recovery from the acute stage of the illness the characteristic tremors and rigidity developed. He now presents the remarkable appearance of a well-marked case of paralysis agitans in a child of 8 years.

Effect of Age.

It will be seen on reference to the table of results how much more serious the results of encephalitis are in the infants and young children than in the older children. Of those affected before the age of 12 months only one has made a complete recovery, while four have become quite mentally deficient, and have remained in that condition up to the time of re-examination in July, 1921.

Severity of the Initial Illness.

The severity of the initial attack of encephalitis appears to be in direct proportion to the after-results which follow it. Some degree of mental deficiency may be expected to result from the illness if the stupor and lethargy persist for three or four weeks in a young child. On the other hand, a short illness, with stupor for a few days only, will probably result in complete recovery. No. 3 is an example. This child, aged 11 months, became ill on April 30th, 1918, and was admitted under the care of the late Dr. Batten, who was responsible for the diagnosis. For six days he was drowsy and could not be wakened. The symptoms began to pass off on the seventh day. The improvement was rapid. The child made a rapid recovery, and is now active and intelligent. This suggests that could some means of treatment be found which would limit the progress of the disease or shorten its course, the results would not be so drastic as we have found them to be.

Conclusions.

1. In the majority of cases epidemic encephalitis in children is followed by permanent after-results, which may affect either the mental or the physical condition.

2. In our series of cases only one-fourth made a complete recovery.

3. The mortality rate of this disease in children is low; 1 in 25 in our series of cases.

4. The results of the mental changes following encephalitis in childhood may vary from complete idiocy to slight mental deficiency. They may also show themselves as affections of the character and habits of the child.

5. The physical changes following encephalitis in childhood include spastic diplegia, hemiplegia, symptomatic paralysis agitans, muscular rigidity, and tremors.

6. The younger the child at the onset of the disease, and the longer the acute stage of the illness, the greater will be the degree of mental deficiency which follows it.

Our thanks are due to Dr. G. F. Still, Dr. F. J. Poynton, Dr. Robert Hutchison, and Dr. H. Thursfield, of the Hospital for Sick Children, Great Ormond-street, and to Dr. R. C. Jewesbury, of St. Thomas's Hospital, in whose wards we investigated the cases we have described.

CASE 6.—B. O. A gunshot wound of the chest had been received; some evidence of fibrosis of the lung. In this case it would be a difficult matter to say positively that there was no tuberculous infection. All the cases are under observation.

One case gave a negative result; a second test of the same sample of blood gave a positive result. This case was a patient undoubtedly suffering from phthisis with tubercle bacilli in the sputum. The first time the blood was tested the hæmolysis in the tube containing antigen and 1½ M.H.D. of complement was not quite complete (for the significance of these remarks reference should be made to my paper containing a description of the technique of the test), but hæmolysis in the highest dilution of complement appeared well over 50 per cent.; hence a negative result was recorded. On repeating the test with the same sample of serum the hæmolysis in the tube containing 1½ M.H.D. was again nearly, but not quite, complete, but this time there was nearly complete fixation in the tube containing 1 M.H.D., and a positive result was recorded.

This serum had been split by Dr. Fleming into three parts, and the tubes re-numbered along with some dozen other bloods. All three parts gave a precisely similar reading. It appears reasonable to presume that the first time the test was performed, by some error in technique an excess of complement had been added to the third tube (i.e., the highest dilution of complement). On reviewing this case it would appear that the result should in the first place have been returned as "doubtful."

* N.A.P.S. = No abnormal physical signs in chest.
T.B. = Tubercle bacilli.

(2) Cases in which there was a suspicion but no definite evidence of tuberculosis.

1.—W. H. Loss of weight; slight cough; no sputum; N.A.P.S.
2.—E. B. Anæmia; general malaise; slight cough; N.A.P.S.; sputum negative for T.B.
3.—C. R. Dry pleurisy three months ago; signs of thickened pleura; general condition very good; no symptoms now.
4.—F. Hæmoptysis, states half a teaspoonful; cough; sputum negative for T.B.
5.—A. H. Dry pleurisy January, 1920; no symptoms now; N.A.P.S.
6.—F. L. S. Cough; some loss of weight; sputum negative for T.B.
7.—M. U. ? Pleurisy seven years ago; slight cough, very little sputum; N.A.P.S.
8.—E. B. ? Hæmoptysis; N.A.P.S.
9.—W. O. Sputum streaked with blood; no evidence of tuberculosis clinically.
10.—A. D. Sent for examination; ? phthisis; no evidence clinically.
11.—B. O. ? Hæmoptysis, probably from throat; N.A.P.S.

Case 22, S. I., undoubtedly had phthisis with T.B. in the sputum a year ago. He now appears perfectly well with no symptoms of abnormal physical signs in chest. I sent this case to Dr. Gosse, with no reference to the result of the C.-F.T., asking his opinion. He replied, "I regard this as a case of arrested pulmonary tuberculosis," which was in agreement with the opinion I myself had formed.

One other case remains for special mention. This was a patient, V. F., who came to hospital complaining of cough, in whose chest I could find no abnormal physical signs. The first routine sputum examination was unexpectedly positive for T.B. The C.-F.T. was negative on two separate occasions. It appeared that this was an error in the test, and some slight error of 1 or 2 per cent. is to be expected in any laboratory test. On endeavouring, however, to confirm the presence of T.B. in the sputum, it was discovered that the patient's cough had cleared up after a week in hospital, and no sputum could be obtained. The possibility, therefore, of an error in the sputum examination cannot be overlooked, and such errors are inevitable. It is certainly very significant that in the only case in which T.B. were said to be present in the sputum which gave a negative result it was impossible to confirm their presence.

A Discrepant Series.

Finally, I should like to draw attention to a series of 50 cases dealt with at the Brompton Hospital in November last. These cases were sent to me by a physician at the Brompton Hospital with numbers only attached to the bloods; the results were returned by me to him, and at a later date I was informed of the clinical diagnosis that had been made. The results of these cases appear to be very contradictory. Of 18 bloods sent to me, and stated to be from patients suffering from phthisis with T.B. in the sputum, 13 were returned as positive and 4 as negative, and 1, three samples of which it appears were sent, was returned once as positive and twice as negative. Three cases gave a positive result in which it was stated there was clinical evidence of tuberculosis. Seventeen cases gave a negative result, in which there was stated to be no clinical evidence of tuberculosis. Eleven cases were returned as positive, in which there was no clinical evidence of tuberculosis.

These results are very different from my previous published results totalling 202 cases, which, though not done under a similar system of numbering the tubes, were nevertheless unknown till after the results had been recorded; and from the present series of 186, which have been done under comparable conditions, as described by Dr. Fleming. Moreover, I have performed the test at the Brompton Hospital upon some 450 other cases, in which the results were emulsions of type 2 (see Table I.) from nut nasgar are agglutinated to the full standard titre in four out of five strains, the fifth one yielding a 50 per cent. agglutination. The type 3 (see Table I.) coccus agglutinated in full. The emulsions from legumen agar gave one-tenth and one-third of standard titre only.

TABLE I.

Strains.	Type.	Media.					
		Nut nasgar (A.-a., 20 %).	Nut nasgar (A.-a., 40 %).	N.N. + buffer salt (A.-a., 40 %).	N.N. + ascitic glucose (A.-a., 40 %).	Legumen agar (A.-a., 21 %).	Legumen agar + blood (A.-a., 21 %).

A.-a., Amino-acid.

Agglutinogenic Capacity.

The differences in the agglutinability of meningococci grown upon varying culture media suggested an inquiry into the agglutinogenic capacity of the several emulsions. Two strains L (type 2) and 6 (type 3) were selected for the purpose. The injections were made into young rabbits weighing 1400, 1400, 1650, and 1750 g. according to the method of Hine.[7] On the first day three intravenous injections of 500 millions meningococci at hourly intervals. The emulsions were previously treated with normal rabbit serum with negative findings. Blood was abstracted from each animal on subsequent occasions. On the tenth day each rabbit received intravenously an additional 4000 millions in one dose. The agglutinations developed are recorded in the accompanying charts A and B.

After injection of type 3 the agglutinations developed from the nut and legumen media, both rose until the sixth day, and fell equally. The serum from the rabbit injected with nut emulsions yielded a higher titre. Similarly, a subsequent injection on the tenth day was followed by a rise, in which the "nut" animal maintained the higher titre. The titre from the "legumen" animal had fallen to zero by the twenty-sixth day; that from the "nut" rabbit was demonstrable up to the fifty-sixth day. Following the injections of type 2 the course of titre was in accordance with precedent, but on a low level, while that from the "nut" animal gave a steep curve, rising to 1000 by the fifteenth day. It had disappeared on the thirty-fifth day. That from the "legumen" animal was just demonstrable up to the fifty-sixth day.

Summary.

1. Variations in culture media are associated with changes in the agglutinability of organisms. Individual strains of meningococci when grown on nut nasgar media become more agglutinable than when they are grown on legumen agar, with or without the addition of blood. The observation may be a possible explanation of some of the "inagglutinable" strains of various bacteria.

2. The agglutinogenic substance in meningococci shows also a relation to the content of nutrient media. It is more active in coccal emulsions prepared from nut nasgar media than those obtained from legumen media. This may have a bearing upon the production of anti-serums.

3. Emulsions of meningococci in normal saline made with freshly distilled water heated to 65° C. for 20 minutes, standardised numerically, and then preserved with 0·5 per cent. phenol, have remained unchanged as to numbers, and sterile for five years. At the end of this period, the agglutinability and agglutinogenic capacity persist practically unaltered.

The expenses of this work have been defrayed by grants from the Medical Research Council and from the Bristol University Research Society.

PROTISTA AND DISEASE:

A Preliminary Note.

BY J. JACKSON CLARKE, M.B. LOND.,
F.R.C.S. ENG.,

SENIOR SURGEON TO THE HAMPSTEAD AND NORTH-WEST LONDON AND ROYAL NATIONAL ORTHOPÆDIC HOSPITALS.

IN "Protozoa and Disease," Part IV., 1915, the chief thesis is that organisms closely akin to Mycetozoa exist in various human pathological states. Last year an amplification of the same view was contained in a new volume of the same series, and I found that I had misinterpreted some objects represented in one of the illustrations. Publication was delayed for me to correct the error, and its elimination left room for fuller notice of biological groups related to the Mycetozoa. The new matter, showing as it does that vegetable protists and not protozoa are the pathogenic agents in the diseases in question, calls for a new title for the work, which is now near completion with the same title as the heading of this article.

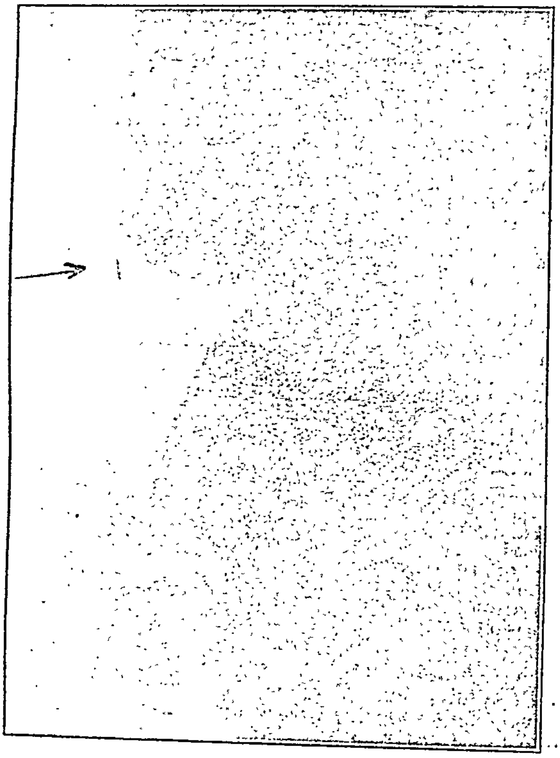
In studying the Chytridians I found that many facts that had arrested my attention in pathology are parallel in this important and interesting group. For instance, Cornu's work[1] on *Olpidiopsis saprolegniæ* showed me that the larger forms of this parasite are almost identical with phases of the parasites known in British pathology as "psorosperms" of cystic ureteritis. There are differences, but the points of accord are such as indicate a close kinship between Cornu's *Olpidiopsis* and Cobbold's psorosperms. Again, in Schroter's paper[2] on *Synchytrium* my attention was arrested by his drawing of interstitial substance between a group of sporangia; this suggested to me an explanation of what I have described as a framework, which appears in molluscum corpuscles in which the protoplasm is in circulation, a phenomenon that occurs about the fourth day in water-cultures.

Synchytrium in a Thistle-Leaf.

Most illuminating of all was the examination of sections of a thistle-leaf infected by a brick-red *Synchytrium*, which I owe to the kindness of Prof. V. H. Blackman and Assistant Prof. R. H. Tabor of the Imperial College of Science and Technology. The sections were made for me by Dr. H. W. Perkins, pathologist to the Hampstead Hospital. The chief features are shown in Fig. 1. The large nucleoli at *d* and *c* have all the characteristics of the intranuclear stage of parasites in the mammary sarcoma, of which a full ocular analysis is given in "Protozoa and Disease," Part II., and the groups of bodies, which in 1895 I demonstrated to the Pathological Society as spores in a secondary syphilitic skin lesion are nearly identical with those seen in this Synchytrian. (Fig. 1 (*i*).)

A wide range of nuclear forms and processes is seen in different species of *Synchytrium*. In 1907 Stevens[3] in three species found nuclear structures, some of which are reproduced in Fig. 2. At *b* and *c* are familiar bird's-eye bodies like those of cancer, and the presence of asters among them agrees with the origin of such bodies as I observed it in the living

She was always able to walk in comfort until August, 1920, when after walking the pain in the knee was much worse, being stabbing in character and deep-seated as though from bone; at the same time she experienced an aching pain in front of the right hip and thigh. The stabbing pain, after resting, became easier, but left the knee aching. The aching pain often kept the patient awake at night, but she never had "starting pains." The aching was worse in damp weather. After sitting in one position for a time the knee became stiff and any movement was very painful. Otherwise the patient was in good health.



X ray photograph of knee-joint, showing broken pointed end of a needle (indicated by arrow) situated apparently on internal border of ligamentum patellæ and posterior to it.

On examination, no swelling of the right knee was detected; no difference in measurement was found on the two sides; no creaking was felt on moving the joint, and both the hip- and knee-joints were freely movable in all directions. On pressure, transversely and laterally, at the lower end of the femur tenderness was elicited.

Drs. C. W. S. Saberton and C. G. Hitchcock X rayed the joint and found the broken pointed end of a needle situated apparently on the internal border of the ligamentum patellæ and posterior to it. The needle was removed by Mr. Gordon Taylor at the Middlesex Hospital in March, 1921. It was found in the extra-synovial fatty tissue round the joint. Since its removal the patient's symptoms have disappeared.

Manchester and Salford Radium Institute.—The institute has just issued its memorandum of association. Amongst other objects are to purchase or otherwise acquire radio-active materials, whether containing radium or mesothorium, or other radio-active substances of any description; to use the radio-active materials so purchased for the treatment of patients, and to supply, lend, or let the same on hire to hospitals, nursing homes, and other similar institutions and to medical practitioners in such form as the institute may determine. The executive will appoint an expert radiologist and a physicist. The scale of charges will be so adjusted as to secure that the undertaking shall be self-supporting.

BRITISH MEDICAL ASSOCIATION.

ANNUAL MEETING AT NEWCASTLE-ON-TYNE.

SECTION OF PREVENTIVE MEDICINE WITH INDUSTRIAL DISEASES.

WEDNESDAY, JULY 20TH.

Sir THOMAS OLIVER, the President, after welcoming the audience, which included non-medical visitors, briefly referred to some of the public health problems of Newcastle as typical of an industrial centre which had been greatly affected by war conditions. He then resigned the chair in favour of Dr. I. G. MODLIN, Vice-President, who urged medical men to take a more lively interest in the municipal work of the towns where they worked.

Capt. WALTER E. ELLIOT, M.P., then read a paper on

The Effect of Health Legislation on the Health of the People.

He opened by remarking that he was more than ever impressed with the value of prevention as against cure, and it appeared that prevention could only be secured by statutory compulsion. He went on to review public health legislation from the time of the first Sanitary Act in England, dealing with removal of nuisances, passed in 1388, up to the creation of the Ministry of Health, suggesting that the great increase in population after the unlocking of the coal-seams in the nineteenth century compelled the passing of sanitary legislation. Medical skill in treatment had not advanced in the same degree as legislation, and he attributed the remarkable decline in infantile mortality and in the deaths from infectious disease largely to Parliamentary action. The expectation of life among individuals of the community had increased by over ten years during the last half century, and that increase was entirely at the useful period of life, for the man of 70 to-day had still the same expectation as a man of the same age 50 years ago. The supply of water, first dirty and later pure, was one of the greatest examples of the effect of legislation on the health of people, for it first enabled them to wash their clothes and get rid of lice and so of typhus, and latterly had led to the almost complete eradication of typhoid. Turning to factory legislation, he said that it was in a large measure due to agitation by laymen, and especially by Lord Shaftesbury, whose deserts had never received due recognition. Reduction in the hours of work and improvements in working conditions were not to be expected to come spontaneously from large employers of labour; the State alone was capable of tackling such problems. The conditions under which the labouring classes were allowed to live in the North compared unfavourably with those in the South of England, and the children demonstrably suffered.

Dealing with the statistics of tuberculosis, Capt. Elliot said that the rapid post-war drop in the number of deaths had never been satisfactorily explained. Some said that the influenza epidemic, which swept the country like a broom, had cleaned out all the weak chests, but the fact remained that non-pulmonary tuberculosis had declined also and to a greater degree. Surely it was, at least in part, a result of the anti-tuberculosis campaign. Turning to the general problems of health legislation, he said that in spite of the great wave of unemployment the vital statistics of the country did not appear to be deteriorating, and therefore the out-of-work "dole" would undoubtedly come under the heading of public health legislation in its broadest sense. Speaking of the men crippled in the war, he hoped that the schemes evolved to train them would be modified and adapted to deal with the casualties of industry in the future. In conclusion, he said that future efforts towards the improvement of the health of people must be devoted to the enlightenment of the public, to the advancement of medical skill, and finally to certain definite compulsory measures, for as yet unplaced in biology. They require a name; and having in view their being a branch of the Chytridiales, hence belonging to the vegetable protists with an affinity to the Mycetozoa; and in view of their being in the plasson state at the initial stage of their intracellular life I suggest the name Plassomyxineæ.

THE VALUE OF THE COMPLEMENT-FIXATION TEST IN PULMONARY TUBERCULOSIS.

A Report to the Medical Research Council from the Institute of Pathology and Research, St. Mary's Hospital.

BY A. LISLE PUNCH, M.B., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE BROMPTON HOSPITAL.

Introductory Note by
ALEXANDER FLEMING, F.R.C.S. Eng.

MY connexion with the experiments which Dr. Punch has detailed in this article has been that of a scrutineer and critic. I have had no part in the performance of the experiments, and no part of the credit that may accrue from this investigation belongs to me. When Dr. Punch began to perform these tests in the laboratories of the Institute of Pathology and Research at St. Mary's Hospital his first care was to convince me that the test was sufficiently good to be worth proceeding with; for this purpose he obtained bloods from a number of patients whom he knew to be suffering from pulmonary tuberculosis. These bloods, some 30 in all, were not disguised in any way, but in every case I saw the tubes at the time the reading was taken, and was thus able to check the results. At the same time these tuberculous bloods were tested there was mixed with them a certain number of normal bloods derived from workers in the laboratories or from patients attending for other diseases. In every one of these cases the result of the test corresponded with the clinical condition.

Having thus satisfied me that the investigation was worth while, Dr. Punch proceeded to deal with a more extensive series of cases, and in this series he had no opportunity of knowing the origin of the blood until the results of the test had been recorded. The procedure adopted was as follows:—

The specimens were collected, some by Dr. Punch, others by workers in this or other institutions. The serum was taken from these specimens and inactivated, the tubes were then handed to me, with a list giving the names and clinical diagnosis (including the information as to whether tubercle bacilli were present in the sputum). I then re-numbered the tubes, sometimes splitting a specimen into two or three parts bearing different numbers, and if there was any possibility of any tube being recognised by some irregularity in size, or by its being cracked, I changed the serum from this tube into another of ordinary appearance. The key to these numbers I retained till the tests were completed, and then I myself recorded on the key the results which Dr. Punch dictated to me, after which I compared the results with the clinical diagnosis with which I had been provided.

I am not here going to enter into any discussion as to the results; they are set forth at length by Dr. Punch. All I wish to vouch for is that Dr. Punch had no means of knowing which blood he was dealing with until he had completed the test, and I had recorded the results which he gave me.

DR. LISLE PUNCH'S REPORT.

The work contained in this paper has been carried out in the laboratories of the Institute of Pathology and Research at St. Mary's Hospital by the kind permission of Sir Almroth Wright. In September, 1920, I published in THE LANCET a method for the performance of the complement-fixation test in pulmonary tuberculosis, and the results of a series of cases upon which the test had been performed. This article consists of an analysis of a second series of cases, and offers further proof of the accuracy of the test when performed by this method. 185 bloods have been tested in this series in the manner described above by Dr. Fleming. On an average 12 sera were tested at each experiment.

Analysis of Cases.

The serum of 185 individuals was examined.

Group I.—C.-F.T. Positive Cases.

71 of the cases gave a positive result.

(A) Cases with tubercle bacilli in the sputum at the time of the performance of the test..	42
(B) Cases in which tubercle bacilli were found in the sputum subsequent to the performance of the test	10
(C) Other cases giving a positive result (these cases are considered in more detail)..	19

Group C.—Case, Initials, and Clinical Condition.

1.—E. J. Crepitations at both apices; a few weeks later a very loud pleural rub over left upper lobe; losing weight rapidly; sputum negative for T.B. on two occasions.

2.—A. L. Complains of cough and loss of weight; no sputum; crepitations at right apex; husband has phthisis, one brother died of phthisis.

3.—A. M. Crepitations both upper lobes; cavitation left upper lobe; tuberculous laryngitis; sputum only examined once as yet; negative for T.B.

4 and 5.—A. M. and D. G. Both apparently healthy save for acne; these and the next case, B.O., are discussed below.

6.—B. O. Gunshot wound of chest.

7.—B. M. G. Cough, no sputum, loss of weight; no abnormal physical signs in chest; father died of phthisis.

8.—B. A. Cough, sputum, hæmoptysis ½ pint two years ago; recent clots; no abnormal physical signs in chest.

9.—O. C. No symptoms or signs; dry pleurisy seven months ago; lost a good deal of weight then, subsequently regained it. Treated in sanatorium.

10.—H. A. Considerable hæmoptysis, no other symptoms; no abnormal physical signs in chest.

11.—L. B. Cough, sputum, crepitations left apex, signs of pleural effusion right base; sputum negative for T.B. on one examination.

12.—E. P. Sputum positive for T.B. in 1915; some cough and sputum at present; weight stationary; no crepitations now in chest; sputum not yet examined.

13.—A. J. Complains of cough, sputum, and loss of weight; sputum streaked with blood two months ago; no abnormal physical signs in chest.

14.—W. H. F. Complains of cough, sputum very slight hæmoptysis; crepitations at right apex.

15.—T. A. Complains of cough and sputum; pyrexia present; crepitations over right lung, especially at base; sputum negative for T.B. on two occasions.

16.—H. P. Cough, no sputum; swinging temperature to 103° every evening; extensive abnormal physical signs in chest.

17.—A. F. Complains of cough and sputum, and loss of strength; crepitations at both apices; sputum negative for T.B. on one examination.

18.—V. D. T.B. in the sputum a year ago; cough and sputum at present; no moist sounds at present in chest; sputum negative for T.B.

19.—L. K. T.B. in sputum a year ago; no symptoms or abnormal physical signs in chest at present.

CASE 4.—A. M. A patient in apparent health, save for some acné on the face; test performed on three separate occasions with three different samples of blood; on each occasion a positive result obtained. What exact interpretation should be put on this case is open to argument. In a series of 100 cases of apparently healthy people, or those suffering from diseases other than tuberculosis, this one (or, if Case 6 is included, two) gave a positive result. This patient may recently have suffered from a small undetected tuberculous lesion, or may be at present suffering from such a lesion, which has not yet given rise to symptoms. In any case it is not surprising that in dealing with so widespread and prevalent a condition as tuberculosis, a positive result should be obtained in a small number (in this series only 1 or 2 per cent.) of apparently healthy people.

CASE 5.—D. G. Also a patient suffering from acne; test performed twice on two different samples of blood; positive result on both occasions. On questioning the patient it was elicited that six months previously she had been treated for enlarged glands in the neck, and on palpation numerous small hard glands could be felt on the right side of the neck.

the statements as to causation of illness made by the patient. These are frequently misleading, as when a post-mortem on a painter certified to have lead colic revealed the presence of a ruptured gastric ulcer.

Dr. **D. W. Inglis** (Hebburn-on-Tyne) was not convinced that the factory door was so closely barred and slammed as had been represented. This opinion was oftener held by those who had not troubled to push against the door, which nearly always gave way if the handle was turned by a combination of tact and bluff. Most factories provided processes which could advantageously be used as sanatoriums for those convalescing from occupational risks, such as lead poisoning. He urged the need of greater knowledge in the profession of the work of the worker.

Prof. **Collis**, in closing a long and interesting discussion, confined himself to maintaining that unhealthy psychology is the outcome of unhealthy physiology, and that the key to industrial unrest lay in health. The medical profession held this key in the hollow of its hand, and owed to the community the service of turning it in the lock.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Thursday, July 21st.

The Section of Obstetrics and Gynæcology met at Armstrong College, Newcastle-on-Tyne, on Thursday and Friday, July 21st and 22nd, at 10 A.M., Prof. **R. P. Ranken Lyle** (Newcastle-on-Tyne), President of the Section, occupied the chair, and in opening the proceedings drew attention to the importance of the subjects selected for discussion. A discussion on the

Rôle of Cæsarean Section in Midwifery

was opened by Prof. **J. M. Munro Kerr** (Glasgow) and Dr. **Eardley Holland** (London).

Prof. **Kerr** observed that his remarks would be confined entirely to a discussion of the indications for Cæsarean section. The question of technique would be considered by Dr. Holland. Apart from, perhaps, the question of toxæmias, there was no subject in obstetric medicine which was more interesting than Cæsarean section. The modern operation dates back to the "eighties," when stitching of the uterus was introduced by Sänger. The name of Murdoch Cameron should also always be remembered in association with this early pioneer work. At that time contracted pelvis and tumours of the uterus and ovaries obstructing the birth canal were the only indications. In 1898 Lawson Tait suggested placenta prævia as an indication, a suggestion which fell almost as a bomb-shell at the time. In later years, grave eclampsia, accidental hæmorrhage, rigidity of the birth canal, prolapse of the cord, and many other conditions have been cited as indications. This is but natural, since the scope of any surgical operation extends as the technique becomes more perfect. He would like to enter a word of caution in this connexion: discretion must be exercised in selecting cases which are suitable. It should be remembered that after the operation the uterus is permanently injured and liable to rupture in subsequent labours. This very fact limits the scope of the operation. Take, for example, the case of the young primipara with eclampsia. Either she must be sterilised at the original operation, or she must run the risk of a ruptured uterus in a later pregnancy. Sterilisation is a crude procedure and not justifiable. Again, there is the case of the elderly primipara where a difficult forceps operation frequently results in the birth of a dead child and much injury to the mother. Cases such as this, where the indication is not absolute but relative, lead one to the conclusion that all obstetric work should be carried out in hospital or nursing home where every facility is available. Personally, the speaker was convinced that the time will come when all primiparæ and many multiparæ will be confined in institutions, as against the present practice. The argument has been put forward that the younger school of obstetricians are too surgically inclined. This he did not believe was the case. In fact it could hardly be so, as every labour was really a surgical operation.

Indications Discussed in Detail.

The speaker then proceeded to discuss in detail the present-day indications for Cæsarean section as shown by the results obtained from an investigation made by Dr. Holland and himself of the work of all practising British obstetricians during the past ten years. Apart from the question of pelvic contraction, which he had left for consideration by Dr. Holland, the indications for Cæsarean section appeared to fall into the following groups: Tumours obstructing the birth canal, eclampsia, placenta prævia, accidental hæmorrhage, malpositions and anomalies of the fœtus, malposition of uterus (post-operative), rigidity of the cervix and vagina, and maternal diseases.

As regards neoplasms, it is generally agreed that if a fibroid or ovarian cystoma produces obstruction to the passage of the child, the only course open is Cæsarean section. The only criticism against this is that occasionally a fibroid which apparently will cause obstruction is drawn up during the early stages of labour, and no difficulty is experienced. The maternal mortality of Cæsarean section under these circumstances is 8 per cent. and the fœtal mortality 19 per cent. The latter is accounted for by prematurity and malformations due to interference in the growth of the fœtus. In the case of ovarian cystomata, the Cæsarean operation is rarely necessary, as the neoplasm is generally removed during pregnancy, or may be displaced from the pelvis during labour. Eclampsia accounted for 236 cases, with a maternal mortality of 30 per cent. The speaker thought that this high maternal mortality might be lowered by operating earlier. The difficulty, however, lies in selecting appropriate cases, as so many recover by ordinary measures. Cæsarean section may be advisable in a few cases, but our practice should be rather to concentrate upon the prevention of eclampsia than to rely upon operation for its treatment. 70 per cent. of the cases are primiparæ and the fœtal mortality is 44 per cent.

With regard to *placenta prævia* Cæsarean section is essentially suitable for central and lateral cases, and should always be selected for central cases in primiparæ. The maternal results are about the same as for version, but the fœtal mortality is much less (15 per cent.). Personally, he had treated six cases of placenta prævia by Cæsarean section with entirely satisfactory results both to mother and child. *Accidental hæmorrhage* occupies an entirely different position from placenta prævia, inasmuch as the child is always dead. The best results are obtained by the treatment advocated by Gordon Ley—viz., rupture of membranes, extract of pituitary, and measures to combat shock. Cæsarean section is required in relatively few cases. In the case of concealed accidental hæmorrhage the maternal mortality of Cæsarean section is 20 per cent. Concerning *malpositions of the uterus*, such as that following *ventral fixation* or the interposition operation for prolapse, Cæsarean section is only occasionally required. It is unjustifiable in the case of *prolapse of the cord*, the fœtal mortality being 75 per cent. With regard to *abnormal conditions of the child*, Dr. Munro Kerr noted the following indications in his series of collected cases: Large fœtus (11), large head (4), occipito-posterior presentation (2), brow presentation (2), impacted breech (3). The total fœtal mortality of these cases amounted to 9 per cent. *Rigidity of the cervix and vagina* is not often considered to be an indication for the Cæsarean operation, but the speaker wondered whether we are correct in taking this view. The severe damage to the birth canal in the case of the mother and the resulting ill-health, together with the high fœtal mortality from forceps trauma, appear to point in favour of Cæsarean section as being a safer alternative. Here again the difficulty is to predict as to what will happen in any individual case.

comparable to my published results, but which I have not had the opportunity to publish.

I am quite unable at present to explain the indifferent results obtained with these cases, but the series which I have detailed in this article has convinced me of the accuracy of my previous published cases, and has also convinced me that the bad results of these 50 cases were dependent upon some fallacy not inherent in the test.

I should like to thank Dr. A. Fleming, Dr. A. H. Gosse, and the medical officers at the St. Marylebone Infirmary for the assistance they have given me in carrying out this work.

Conclusions.

It would appear that the above results are strictly comparable to those obtained by me previously and published, and that the conclusions drawn from the previous results are confirmed by the present series—namely:—

(1) That in the complement-fixation test we have a reliable means for the diagnosis of an active or recently active tuberculous lesion (pulmonary). It must be emphasised that it is the pulmonary form only of the disease that is dealt with in this paper.

(2) That a negative result is as reliable an indication of the absence of such a lesion as a positive is of its presence.

Clinical Notes:
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

TWO PROBABLE CASES OF AMBULATORY ENCEPHALITIS LETHARGICA.

By C. EUSTACE WILLIAMS, M.R.C.S. ENG., L.D.S.

THE following cases of what appeared to me to be encephalitis lethargica of the ambulatory type came under my notice during the early part of this year, and are chiefly interesting because the exact dates of onset of the initial symptoms were obtainable in both cases.

CASE 1.—The patient was a woman, aged 23, recently married. Up to Jan. 8th she felt quite well; on that day, however, she developed a feeling of nausea which lasted for three or four hours. This continued every day until the 21st, when she was attacked by a fairly severe frontal headache. The next day she consulted me and was given a mixture of tinct. gelsemii ℳv., soda bromide gr.v., and water three times a day. On the 25th the patient began to see double; after three days this suddenly passed off, leaving haziness of vision. On the 29th lethargy made its appearance, the patient feeling an overwhelming desire to sleep after tea; she slept each evening for about four hours, during which time it was possible to wake her up, but she would almost immediately go to sleep again. The medicine was now discontinued, and the symptoms continued until Feb. 9th, when the patient was again brought to me. She slept well at night time, was not refreshed on rising, could not remember things as well as formerly, and felt disinclined for work.

Examination gave the following details: Pupils equal and regular, pupillary reflexes slow; no ptosis, no Romberg; pulse, temperature, and respiration normal; no tremors of hands or tongue; no muscular twitching; cerebration slowed, heart and lungs normal. The patient was given hexamine gr.v., acid soda phosphate gr.x., and water three times a day, and instructed to go to bed. During the following week the temperature never rose above normal. The headache, disordered vision, and lethargy improved; on the eighth day patient was allowed to get up, and next day to go out. On the 25th vision again became blurred, and so she was sent to Dr. Fletcher Stiel, ophthalmic surgeon, who reported: "I certainly agree that she is a mild and suppressed case of lethargic encephalitis. Her actual vision is 6/6 in either eye and her fundi are normal, but her extrinsic muscles are entirely without coördination. I have carefully tested each muscle separately and the result is not that of an ordinary heterophoria at all. There is very definite paresis of third nerve on right side and of the sixth on left side."

Blurred vision continued; three weeks later patient complained of a return of intensified headache and said that her left arm jerked at night. The hexamine mixture was dropped and a strychnine and iron tonic recommended. This was continued, and patient made a gradual and uninterrupted recovery.

CASE 2.—The patient was a woman, aged 23, married, with one child. She was suffering from syphilis, and was having her second course of N.A.B. injections when she suddenly ceased attending the V.D. clinic. Shortly after she came to me with the following history: On the morning of Feb. 1st she woke up with a bad frontal headache and a feeling of heaviness behind the eyes. During that day she felt drowsy but did not actually sleep. Next day she complained of "pins and needles" in both arms and legs, and if she concentrated her vision on any object she seemed to go blind. She now found great difficulty in keeping awake, but could be roused to talk or take some food before going off to sleep again. These symptoms continued until she came to see me on the 14th, on which date she developed a feeling of nausea.

On examination patient presented a dull, heavy appearance, with face pale and practically expressionless; cerebration and speech were much slower than usual and she was in a somewhat lethargic condition. Physical examination revealed pupils equal and regular, pupillary reflexes rather sluggish; no strabismus, no nystagmus, no ptosis; pulse, temperature, and respiration normal, no Romberg, paralysis, or obvious paresis; slight tremors of hands and tongue, no skin eruptions, heart and lungs normal. Patient was given a hexamine mixture and sent to bed. Three days later she was feeling much better, so got up. Symptoms gradually passed off, lethargy being last to go, and by the 21st she was carrying on her ordinary household duties. She was now given a tonic, and for the next month, with the exception of occasional attacks of giddiness, was her normal self. She then resumed her treatment for syphilis.

The following note was supplied to me by Dr. W. P. White, medical officer to the V.D. clinics of Grimsby and Lincoln, with reference to Case 2:—

"The patient attended my clinic on Oct. 13th, 1920; her baby was suffering from congenital syphilis; her husband's blood gave a positive Wassermann reaction, and her own also gave a strongly positive reaction. Treatment was at once commenced, intravenous injections of N.A.B. being given once weekly with gr. i. of hydrarg. c̄ cret. by mouth t.d.s. The first course consisted of two injections of 0·15 g. N.A.B. and six of 0·6 g. Patient then had a month's rest, after which her blood again gave a positive reaction. The second course of treatment was then commenced; after the first three injections she ceased attending; this fact I attributed to ordinary slackness. The patient had told my clinic nurse that she found it very difficult to keep awake if she rested for a few minutes from her house-work. A few days later the patient's husband informed me that his wife was suffering from sleepy sickness. Later on I saw Dr. Williams, who informed me that he was attending her for encephalitis lethargica." This would point to the fact that N.A.B. and its allied arsenical compounds are not a cure for so-called sleepy sickness."

I have seen both patients within a few days of date of writing (June 21th); both are quite recovered, showing no trace of their recent indispositions.

A FOREIGN BODY IN THE KNEE-JOINT FOR 13 YEARS.

BY ALFRED C. SHARP, M.D. GLASG.

THE patient was a young woman, aged 20, who visited Harrogate for spa treatment in September, 1920, on account of pain in the right knee and thigh.

She stated that when she was 7 years of age her right knee was painful and swollen, and a splint was applied for three months. She considered the trouble originated with a knock when 6 years old. She was then all right for seven years, at the end of which period the pain and swelling returned. The knee was thereupon kept in plaster of Paris for six months with no improvement. Later the pain came on at intervals, and although she had several different treatments no improvement occurred.

Dr. **Walter Swayne** (Bristol) was of opinion that a collective investigation on the lines of that carried out by Prof. Kerr and Dr. Holland should be made every two years instead of every ten, as views and practice alter rapidly, and many valuable years are wasted whilst opinion is being moulded. In Bristol, contraction of the pelvis is not common, but other complications of pregnancy and labour, especially eclampsia, are very common. Statistics had brought out very clearly, he thought, the importance of antenatal care. At the same time, he considered the present-day practice to fly to Cæsarean section for any complication of labour essentially wrong.

Dr. **R. J. Johnstone** (Belfast) thought that the thanks of the Section were owing to Dr. Holland and Prof. Kerr for the very great amount of trouble they had taken in getting together the statistics upon which their opening papers had been based. He proposed that the expenses of the investigation be defrayed out of the British Medical Association funds set aside for research. The proposition was seconded by Dr. W. Robinson and carried unanimously. The President of the Section undertook to bring the matter to the notice of the Council of the Association. Dr. Johnstone also suggested that forms be supplied to every obstetric surgeon to complete at the time of operation. This would make the statistics more reliable and be easier for individuals. With regard to the points that had been raised in the discussion, he was of opinion that Cæsarean section was quite justifiable in most of the cases in which it was performed. Personally he had never regretted doing the operation, but he had certainly regretted not doing it. He was very interested in the technique described by Dr. Holland, but he could not agree that silk-worm gut or silk were the only sutures to employ. His practice was always to use continuous catgut in three layers, including the decidual layer. He also did not agree with Dr. Holland's remark on the musculature of the uterus, and thought that he was entirely wrong in what he had said about the muscle tending "to pull open" the uterus. Twenty-four hours after labour the consistence of the uterus was the same as that of the non-pregnant organ. The uterus, in other words, had tonus, but not undue contraction.

Mr. **Gordon Ley** (London) supported Dr. Holland's view with regard to the action of the uterine musculature after incision. A wound in the uterus, either made by Cæsarean section or by rupture, always gapes. It most certainly does so at labour and probably this is the tendency afterwards. A ruptured uterus tends, in fact, to herniate through the rupture. With regard to indications for the Cæsarean operation, Mr. Ley quoted a case of post-maturity in which the patient was aged 45 and her husband 72. He had performed Cæsarean section in this case with entirely satisfactory results.

Mr. **Beckwith Whitehouse** (Birmingham) referred to the technique of lower segment Cæsarean section. Subsequently to Prof. Kerr's paper at the Royal Society of Medicine in 1920, he had performed the operation twice, but on each occasion had had some difficulty. At the first operation there was much troublesome venous hæmorrhage. On the second occasion Mr. Whitehouse had had considerable difficulty in extracting the child. Apart from these criticisms, the operation appeared to be based upon sound principles and possibly his early difficulties would disappear with further experience of the method. He was much interested in the change of opinion that had taken place during the past ten years with regard to the treatment of placenta prævia. About ten years ago he was present at a discussion at the Royal Society of Medicine when Dr. Jellett expressed the opinion that although he did not consider the Cæsarean operation wrong for placenta prævia, he could not see the necessity for it. This was the opinion expressed by the majority of speakers at that discussion. To-day the position was reversed, and we were all, quite correctly he thought, advocating Cæsarean section as being the ideal operation for many cases. The difficulty lay in deciding upon the suitable cases for operation. Were all cases to be treated by section, and, if not, what was to be the deciding factor? Personally he limited the operation to cases at and after the eighth month of pregnancy where there was a reasonable chance of saving the child. The important thing for the medical profession to recognise was that version was by no means a safe operation for the mother and was, of course, most fatal to the child. At the Maternity Hospital, Birmingham, statistics over a period of ten years proved that version for placenta prævia was associated with a maternal mortality of over 4 per cent., and a fœtal mortality of over 70 per cent. This was deplorable, and he could not help thinking that Cæsarean section would show very different results. He would like it to go forth from the Section that placenta prævia is a complication of pregnancy which always requires nursing home or hospital treatment, and in which Cæsarean section will very probably be required in order to obtain the best results.

Dr. **J. W. Bride** (Manchester) called attention to the statistics of Manchester cases of Cæsarean section contained in Dr. Holland's report. 642 cases of Cæsarean section had been performed in Manchester in the period under review, with a gross maternal mortality of 7·7 per cent. In eclampsia the mortality had been high and in cases performed for contracted pelvis, 25 deaths had occurred, chiefly due to general peritonitis. The conclusions that obstetric surgeons had arrived at in Manchester were that Cæsarean section could be performed with very little risk to the mother except in infected cases, that it was not a suitable operation for eclampsia, but that it was attended with good results in placenta prævia, especially in primiparæ. Rickets was a very common disease in Manchester, 1000 cases occurring in female infants per annum. This probably accounted for the high proportion of cases of contracted pelvis in the Manchester report.

The **President** expressed the thanks of the Section to the speakers for the valuable discussion, adding that the exchange of views that morning would undoubtedly influence obstetric practice in this country. It was evident, for example, that in eclampsia the indication for operation was very doubtful, as the results were no better if as good as with the older treatment. In placenta prævia, on the other hand, the reverse was the case. One of the most salient facts, he thought, that had issued from the discussion was the importance of conducting obstetric work as far as possible in an institution. Probably in 10 or 15 years all maternity work will be carried out in nursing home or hospital. This, in association with pre-maternity work, will reduce both maternal and fœtal mortality and was the ideal to be aimed at.

Prof. **Kerr**, in reply, wondered if the unfavourable results quoted by Lady Barrett as seen in Vienna were due to the operation of lower segment Cæsarean section being performed for septic cases. This, of course, was the original indication by Thomas. There was an essential difference in advocating the operation for uninfected cases, the indication now being to secure a sounder uterine scar. Mr. Whitehouse had mentioned two difficulties in performing the operation. He quite agreed that difficulty in delivering the child did occur at times, especially if the head was deep in the pelvis. This was one disadvantage of the operation. The other complication of hæmorrhage was not so serious, as it could be controlled, and, furthermore, it occurred also in the classical operation. The point raised by Dr. Johnstone had been answered by Mr. Ley. A wound in the upper segment of the uterus did gape, although perhaps not quite in the graphic manner suggested by Dr. Holland.

Treatment of Advanced Malignant Disease of the Cervix.

Dr. **Arthur Burrows** (Manchester) read a paper upon the treatment of advanced malignant disease of the cervix uteri by means of radium. The speaker, although there was at present a wave of feeling against State interference of any kind, it would be tragic if this blinded the people to the great results of public health legislation in the past.

Discussion.

In the discussion that followed, Dr. T. EUSTACE HILL (C.M.O., Durham) said that whilst it was impossible to legislate in advance of it, he felt that some of our legislators had not felt the pin pricks of public opinion, as evidenced by their failure to get the Milk and Dairies Act put into operation and thus stop the supply of tuberculous milk. He urged the pressing need for reconsidering with a view to codification all the Public Health Acts.—Dr. A. E. COPE (Public Vaccinator, Westminster) said that public health administration was in advance of public opinion; the neglect of vaccination showed the need of education.—Dr. MILLER (C.M.O., Radnor) maintained that there were too many forms to be completed, too much correspondence, and too much "red tape" in connexion with health administration. The least possible interference was desirable.—Dr. D. A. COLES (Gas Light and Coke Co.) drew attention to the neglect of minor injuries in factories, and the lack of means to compel workpeople to use protective appliances.—Dr. DAVID MCKAIL (Glasgow) claimed that municipalities had shown the way to the State rather than the reverse, and contended that the fall in the infantile mortality rate was associated with the decline in the birth-rate.—Dr. W. F. DEARDEN (Port M.O.H., Manchester) thought that legislation had been slow. The medical staff of the Home Office was too small as compared with that of the Ministry of Health.

Capt. ELLIOT, in replying, said that the establishment of the Ministry of Health was too recent for results to be seen. He held that the provision of all funds for health purposes directly from London would be disastrous by discouraging local initiative. He thought that legislation had already done enough to warrant a continuance in the same path.

THURSDAY, JULY 21ST.

Prof. E. L. COLLIS opened a discussion on the *Importance of Industrial Medicine to the Community* in a paper which appears substantially at length in another part of this issue.

Dr. T. M. LEGGE (Home Office) sent a letter in which, while agreeing with the need for and the value to be gained from industrial medicine, he held that the door of the factory must be opened wider to the profession before it can be effectively established. He pointed out that the large sums of money demanded from employers for health insurance, the benefits of which may be a little dubious, may deter them from embarking upon preventive hygiene.

Sir KENNETH GOADBY (Medical Referee for Industrial Poisoning) expressed general agreement with the opinions stated by the opener of the discussion. An expanded version of his remarks appears in our original columns.

Capt. ELLIOT held that coöperation with labour was a necessity for establishing industrial medicine, since the industrial doctor must be a trusted personal friend just as is the family practitioner. He felt dubious as to whether the psychology which expressed itself as labour turnover and laziness was really pathological, rather than being the effect of monotony and specialisation; for the spirit of man revolts against eternal efficiency; man prefers to remain the eternal amateur. Parliament is concerned with big broad issues in labour matters, and he held that the problem of industrial health was a great issue with immediate bearing upon all industrial legislation. One important aspect was that of industrial convalescence; here the work of the Ministry of Pensions carried on for incapacitated soldiers provided the largest medical organisation in the country, with 1,200,000 patients under scientific control. Even so 10 per cent. were unrecoverable—i.e., 120,000 persons needed short-time employment. Thus an experiment on a great scale was in progress of untold value to industry. Industry should profit thereby, and persuade Parliament to maintain and devote to the needs of peace the activities of the Ministry of Pensions; but action must be taken soon or the time will slip past. The influence industrial medicine can exert upon labour unrest cannot be doubted: for the man broken in industry sitting at the rich man's gate provides an appeal, greater perhaps than the individual case justifies, but an appeal which must be heeded.

Dr. DEARDEN pointed out how industrial medicine had become a matter of public interest, and that development was needed. He advocated a medical service on the lines followed by Belgium, where with the reconstruction of industry has advanced pari passu a reconstructed medical organisation with an adequate and independent staff and laboratory facilities for research. We need efficient inspection of adolescents at work carried out by a semi-independent staff. At present the medical staff of the factory department was too small; it required increase and distribution in the industrial centres. In addition, the factory door must be opened to the general practitioner, who cannot give the service he is capable of unless he is acquainted with the industrial risks of his district. Arlidge in the past, and Prosser White to-day, are instances of the value of the general practitioner. He dwelt upon the importance of medical selection for work, instancing the folly of allowing a girl with poor eyesight to become a seamstress, and considered that defective eyesight unnoted was a prolific cause of labour wastage.

Dr. H. KERR (M.O.H., Newcastle) congratulated industry on the development of canteens for supplying operatives with food; but pointed out that, since kitchens were not factories, the industry of cooking was not adequately supervised; it fell between the two stools of factory inspection and the local public health service. He made out a good case for handing over this work to medical officers of health who already have other responsibilities in relation to food.

Dr. MCKAIL felt the need for the factory door to be opened wider to doctors; particularly he considered that examination of young persons for employment without the power of following up was an anomaly. The general practitioner would gain greatly by being brought more into public health work, both in schools and factories. The need for industrial convalescence was great; industry should carry responsibility for those whom it disabled; each worker should be "on the strength" of his industry, and his productivity, even when limited by disability, should be used to its utmost. Education of workers in the risks of occupation was urgently needed to minimise illness and prevent accidents.

Dr. W. DUNCAN (Regional M.O., Stafford) considered that the whole question of industrial medicine was one for the general practitioner. His interest is direct, for the healthier are the panel patients, the less work is there for the panel doctor. He must acquaint himself with the district industries by personal inspection. He must approach employers and get the goodwill of the workers. He must convince both that there is work which he can do which it is to their advantage to have done. The folly of prohibiting light employment needs to be pointed out to friendly societies. Indeed, in this matter the practitioner must act, and act quickly, or he will lose his position.

Dr. MILLER dwelt upon the value of juvenile advisory committees in introducing to work children as they leave school, and asked here for closer coöperation from certifying factory surgeons. He asked, not for the creation of more officials—there were enough already—but for the extension and improvement of the services already in existence.

Sir T. OLIVER was in agreement with extended use of the general practitioner, who to-day does not visit his patients while they are at work, and is not acquainted with their occupational risks. The results are often unfortunate, as he accepts without demur speaker had no belief in fissures and abrasions as being a common cause of dyspareunia. It is frequently nervous in origin, but may be due to an irritating leucorrhœal discharge and is curable by curettage. In the same way pruritus vulvæ, attributed to the nervous system, may often be cured by a thorough sterilisation of the vulva and vagina. Operations such as division of the cutaneous nerves appeared to be unnecessary. *Amenorrhœa* had long been known to be associated with a nervous element or nerve shock, especially in cases of fear of pregnancy, or desire for maternity. The same causes often account for examples of so-called "phantom tumour." It must not be forgotten, however, that enteroptosis may on occasion be the cause of this condition. Prof. Donald observed that he was no believer in the "mechanical cause of disease" as a whole, and quoted the case of large ventral hernias of immense size in patients without a single symptom. *The bladder* is very frequently associated with a train of nervous symptoms and diagnosis may at times be difficult. Incontinence in young women is often nervous in origin and without obvious cause. It is amenable to moral treatment. In middle-aged women, on the other hand, it is more usually due to cystocele. Retention of urine after operation is generally of nervous origin. Frequency of micturition may, on the other hand, be due to nervous causes or to a definite lesion of the bladder, such as cystitis of *B. coli* origin, a deep cervical laceration, or, in elderly women, to atrophic changes in the vagina. The diagnosis between symptoms due to a neurosis and those caused by actual disease must depend upon accurate knowledge gained from experience in bimanual examination. If any gynæcological lesion is discovered the question should be asked, "Will the symptoms be cured by removal of such a lesion?" Also, because a woman is in some respects neurotic, this must not be adduced as a reason for not treating any lesion present actually causing symptoms.

Prof. Donald, in conclusion, called attention to certain points of treatment. The use of specula in the consulting room, he thought, was unnecessary if the sense of touch is developed sufficiently. The uterine sound also in his opinion should be reserved entirely for use in the operating theatre. Pessaries he stigmatised as being useless and generally harmful. Most patients wearing pessaries had, he said, been educated to the use of them and could generally be educated out of them. Vaginal douching was harmful when no actual indication for its employment existed. Tampons also, he thought, had no curative effect. Massage and rest undoubtedly did good in some cases, but many neurotic patients rest too much. Exercise would be more beneficial. With regard to the question of operative treatment, the existence of the neurotic element should make the gynæcologist more guarded in his conduct. Objective symptoms are always more important in providing indications for operation than subjective. These remarks particularly applied to operations performed for fixing various organs. How many of these operations, the speaker asked, were performed without the least relief to the patient's symptoms? In a very large proportion of these women complaining of symptoms of neurotic origin, all that was required was a plain talk. It was often not a pleasant duty and perhaps not one liable to make for popularity, but it must on occasion be done. Prof. Donald observed that he had purposely made no reference to psycho-analysis. He had had no experience of it, and he considered it outside the sphere of gynæcology.

The Neurological View.

Dr. FARQUHAR BUZZARD (London), continuing the discussion, said that he should define neurasthenia as being a disorder of mind whereby the ordinary activities of life were rendered impossible. The normal mechanism controlling this had broken down. This morbid condition had no physical signs, but was nearly always associated with a group of symptoms of which the most important were depression, insomnia. irritability, restlessness, and a loss of the sense of proportion. With these symptoms, owing to the loss of a controlling influence, there was frequently in addition an exuberant growth of certain mental elements. Anxiety, fears, and various obsessions, for example, assumed proportions which on occasion were put down as being the primary cause of the condition. They were in reality but symptoms or disorders of function. This being so, it followed that mistakes of treatment were sure to follow the adoption of such an erroneous view. The gynæcologist, when confronted with a probable case of neurasthenia, must satisfy himself that no actual physical cause exists to explain the train of symptoms. Correct diagnosis must therefore guide his treatment. Some of the most difficult cases of neurasthenia were those in which the patient appeared not to have a care in the world. The cause was a very difficult problem to elucidate. There must, however, be a cause in every case, but it may be as trifling as the blow which in some sensitive individuals produces a large bruise. Many factors might be concerned, psychic, static, endocrinic, &c. The inherent factor was perhaps the most important, and individual differences should not be overlooked. The mental form of a woman differs as does her outward appearance, and every woman and girl is not equipped with the same power of resisting outside influences, pathological and otherwise. This very fact accounts for some of the nervous disorders occurring amongst school-girls, who with our present social system, are all forced to follow the same régime. At puberty and during adolescence the inherent factor occupied considerable dimensions. New instincts were being developed with the assumption of function of the genital organs, and a breakdown was very likely to occur in the combat between these primitive instincts and social ideals. Visceral sensations may and do assume a painful character when the higher powers are upset. There is no such thing as imaginary pain, and much of the so-called ovarian and other pain in women probably had a basis in the facts noted above. Fatigue, quite apart from pain, is often associated with sexual instincts in women, and restoration to health may be effected by rest alone. *Fear* and *fright*, on the other hand, are often the basis of neurasthenia, and so a vicious circle results. Many women from girlhood onwards live in an atmosphere of fear, often unexpressed. The onset of menstruation, sexual intercourse, pregnancy, lactation, and the dread of carcinoma are all factors in a woman's life, and in many cases provide an element of fear. This is often exaggerated from lack of education. It is inconceivable how great at times this lack of knowledge of the ordinary facts of life may be. The element of fear at times prevents a woman from expressing her symptoms to a gynæcologist, in case he should discover signs of serious disease—e.g., carcinoma. Rest in many patients suffering from early neurasthenia is all that is required. The speaker said that he had no sympathy with the surgeon who gets his patients up too soon after operation, or with the obstetrician who places a time-limit on the duration in bed after a confinement.

Dr. Buzzard thought that the habit of attributing nervous symptoms to certain ages, especially the climacteric, was to be deprecated. Many women pass through the so-called "dangerous age" without any troubles whatsoever. 35 to 45 was the commonest age for neurasthenia is women, and in many cases the actual menopause was not near. Both married and single women had individual causes of neurasthenia peculiar to their state. In point of fact civilisation had imposed certain penalties upon women that did not exist in the case of men, and this was probably responsible for the greater incidence of neurasthenia amongst women. The actual menopause may have an influence, but, as often as not, has none. This is confirmed by the absence of neurasthenic symptoms in a patient passing through an artificial menopause, unless a predisposing cause is also present. In conclusion, the speaker said that with regard to the endocrine glands, although a few years ago he had been biased in their favour, he now had no use for them. He could not recall any case of neurasthenia in which ovarian or mammary extracts had proved to be of any value.

The safest procedure is to have the patient in a home or hospital where operative treatment can be adopted at once without risk. Concerning severe *maternal constitutional disease*, the speaker noted 42 cases of cardiac lesions with a maternal mortality of 20 per cent. following Cæsarean section. Two cases of advanced tuberculosis had been treated by the operation with no death. Single cases of diabetic coma and chorea had proved fatal. In conclusion, he observed that it is impossible to lay down rigid and absolute rules in obstetric practice. The wise obstetrician is he who is not prejudiced. One thing was certain, however, and that is that our art is slowly progressing as the years pass by.

Technique and Risks of the Operation.

Dr. **HOLLAND**, continuing the discussion, said that many obstetric surgeons to-day were not satisfied with the classical operation of Cæsarean section and thought that there was an alternative procedure. What was required was to decrease not only the mortality but also the morbidity of the operation and so extend its scope. Forty years ago Cæsarean section had been standardised much as we do it to-day and the classical operation had deservedly stood the test of time. Its mortality had reached a very low level, and consequently its indications had been extended, and as many thought somewhat recklessly. A very striking contrast as regards mortality was evident in the older and more recent figures. Spiegelburg (second edition, 1882) gives a 50 per cent. mortality, with absolute pelvic contraction as being the only indication. In Amand Routh's important monograph statistics were collected over a period of 20 years, from 1891 to 1910, and the following figures were published relating to maternal mortality:—

	Cases.	Maternal mortality per cent.	
Not in labour	245	3·6	2·9
In labour—			
Membranes unruptured	224	2·2	
Membranes ruptured		10·8	
Frequent examinations		34	

Prof. Kerr and he had thought the time opportune for a further investigation relating to mortality and indication. They had been able to collect records of 5000 cases performed by British obstetric surgeons from 1911 to 1920. Of these, 3500 were cases of contracted pelvis. The results regarding mortality were as follows:—

	Cases.	Deaths.	Per cent.
Not in labour	1102	17	1·4
Very early in labour	338	7	1·8
Very long in labour	205	21	10
After forceps	102	27	26

The fœtal mortality after forceps was 27 per cent. due to intracranial injuries. Amongst the causes of death in the "clean" cases were general peritonitis (9), pulmonary embolism (3), paralytic ileus (1), intestinal obstruction (1), chronic bronchitis (1). Personally, Dr. Holland thought that the minimal limit of maternal mortality had been reached.

The disadvantages attaching to the classical operation might be classed under four headings: (*a*) risk of sepsis in infected cases, (*b*) risk of rupture of the uterine scar in subsequent pregnancies, (*c*) risk of intestinal complications from adhesion of intestine to uterine scar, (*d*) risk of general peritoneal adhesions. Rupture of the uterine scar has been shown by statistics to occur in 4 per cent. of all cases. This the speaker attributed to the structure of the uterine wall, the position of the incision in the uterine wall, and the liability to infection of the uterine incision. The uterus is a very powerful muscle and its contractions tend to interfere with subsequent healing of any wound made in its substance. The vertical incision as usually made in the upper segment in Cæsarean section tends to gape transversely and accurate approximation of the cut surfaces is difficult. The chief essential in healing is absolute rest, and this is far from being the case in the upper segment operation owing to contraction and retraction. As regards technique the speaker advocated the avoidance of all hurry. Interrupted sutures taking a wide bite of the uterine wall should be introduced, each suture being tied separately. Closure of the uterine peritoneum was most important, as sepsis arises not so much from infected liquor amnii as from a slow leakage through an infected scar. The uterus should be fully retracted before suturing is attempted. The best material to use is silkworm gut. Silk is the next most suitable. Catgut could not be recommended.

Dr. Holland next proceeded to discuss Cæsarean section performed through the lower uterine segment, an operation which had recently been revived by Prof. Kerr. The technique of the operation was described in detail, the speaker favouring a transverse incision through the uterine wall. He had performed the operation upon nine occasions and was very pleased with the results. The technique is certainly more difficult, but the advantages to the patient quite justify its adoption. The advantages which Dr. Holland and Prof. Kerr claim for the operation are as follows: (1) the uterine wound lies in an inactive area and healing is facilitated; (2) the uterine wall is thinner and suturing is more efficient; (3) the incision lies in a less vascular area and therefore there is less hæmorrhage during the operation; (4) adhesions cannot occur, since the wound in the uterine wall is covered by the bladder; (5) for the same reason infection of the peritoneum is less likely to occur; (6) there is less disturbance of the general abdominal cavity; (7) the uterine scar is in a safer area for a subsequent pregnancy and not so liable to rupture.

Discussion.

Dr. **WILLIAM ROBINSON** (Sunderland) said that the figures brought forward by the openers of the discussion made one thing quite certain, which was that practitioners should, in cases of expected difficulty, call in the services of a consultant before the membranes ruptured. The indications for Cæsarean section mentioned by Prof. Kerr were good, but the difficulty, especially in placenta prævia and eclampsia, lay in the fact that it was not possible to say which patients would recover without operation. Many undoubtedly did so. He quite agreed that all primiparæ should be treated in nursing home or hospital and not in private houses.

Lady **BARRETT** (London) said that the discussion was very useful in that all points of view could be expressed. She was glad that the relation of fibroids to Cæsarean section had been raised. Personally, she had on several occasions performed myomectomy at the fifth month of pregnancy and labour had subsequently been normal. With regard to eclampsia, the point had been raised that if the operation had been performed early the results would have been better. This was not always the case, as in a patient under her care in whom albuminuria and nausea developed with remarkable rapidity. She had performed Cæsarean section and eclamptic convulsions developed post-partum. The patient died, and yet other patients, apparently worse, got better after Cæsarean section. The whole thing was very puzzling. For placenta prævia, especially in primiparæ, Lady Barrett was quite sure that Cæsarean section was the ideal operation, and was of opinion that it is in this group that the mortality rate will be reduced. In the case of accidental hæmorrhage, on the other hand, she thought that Cæsarean section would largely disappear as a means of treatment. The operation may prove, however, to be very useful in the case of pregnancy complicated by severe cardiac disease. The results of this complication were at present very disappointing. With regard to the new technique, she was much interested in the facts put forward by the openers of the discussion. At the same time she had seen lower segment Cæsarean section performed frequently in Vienna before the war and was not impressed with the results. The majority of the cases died from sepsis. As to the question of less liability to rupture of the scar the operation must stand the test of time.

associated with the function of the ovarian internal secretion, and Bond believed the two to be antagonistic. Certainly the uterine secretion is profoundly influenced both in its physical and physiological properties by the presence of the ovary. Menstruation was a natural aid to fertilisation and pregnancy, with a means of control so elaborate that its balance was easily upset and anomalies of function were frequently encountered.

Cessation of Menstrual Hæmorrhage.

The machinery of the factors which normally caused cessation of menstrual flow—factors all-important in the production of pathological hæmorrhage—was undoubtedly complex. If the quantitative theory of ovarian secretion were accepted, it would be understood that when the fixed degree of concentration was reduced the stimulus was removed and the menstrual flow ceased. Similarly, if the ovarian hormone were regarded as a complex body requiring for its physiological action the aid of calcium, a stage must be reached when it became inactive owing to the outpouring of calcium salts by the uterine glands. Furthermore, the thrombokinetic function of the endometrium had to be considered; as soon as the uterine glands stopped secreting, the thrombolytic factor ceased and the endometrial vessels were immediately closed by rapid physiological thrombosis. Finally, the uterine muscular contractions taking place during "menstrual labour" exerted some influence in controlling hæmorrhage by limiting and regulating the supply of blood to the endometrium. Periodicity of the function was probably entirely dependent upon general metabolism, in which the whole "sex complex" took part. It was the product of heredity, evolution, and environment, and was comparable to the age of puberty or of the menopause.

Pathological Uterine Hæmorrhage.

If bleeding occurred at what was normally the active period of the menstrual cycle, the loss was customarily termed menorrhagia, and if during the so-called quiescent period, metrorrhagia. This classification was clinically unsatisfactory; for some time the speaker's practice had been to group cases under one of the following headings:—

1. *Menorrhagia.*—Excessive hæmorrhage relating simply to the quantity of blood lost at a menstrual period.
2. *Menostaxis.*—Excessive menstruation as regards duration of the flow; the loss in this case might not be excessive, but simply a long drawn out period.
3. *Epimenorrhœa* (a term introduced by Blair Bell).—Too frequent menstruation—i.e., alteration of rhythm. When a combination of (1) and (3) exists, Blair Bell had suggested the term "epimenorrhagia."
4. *Metrostaxis.*—Uterine hæmorrhage having no relation with menstrual bleeding, including all hæmorrhages before puberty and after the menopause, and all irregular bleeding during a woman's active sexual life.

This classification he had found very useful in practice. All excessive uterine bleeding was due either to general or local causes; speaking very generally, the former predominated in young patients and the latter in married and elderly women. By far the greatest number of cases of hæmorrhage requiring attention occurred either at the commencement or towards the close of active sexual life; a knowledge of the normal microscopical appearances of the endometrium at different stages of the menstrual cycle was essential, as diagnosis of the cause of pathological bleeding must be based upon abnormal appearances of fragments removed by the curette.

Abnormal States of the Endometrium.

There were three abnormal states of the endometrium which demanded consideration—hypertrophy (diffuse or localised), atrophy, and hyperactivity.

Hypertrophy was not uncommon in minor degrees and gave rise to pure menorrhagia; it was commonly a late result of septic infection of a parous uterus, but also occurred quite independently of this factor. In multiparæ it sometimes supervened upon rapidly repeated pregnancies, and in nulliparæ might be associated with chronic pelvic congestion from various sources and hyper-oöphorism. The diagnosis of hypertrophy was readily made by means of curettage; treatment depended upon the cause underlying it. Sometimes curettage alone effected a cure, at other times the intra-uterine application of radium, partial oöphorectomy, or even hysterectomy was required.

Atrophy produced hæmorrhage because of the absence of endometrial stroma with its associated thrombokinase. Normally, as the blood escaped into the tissues, it was brought into contact with a tissue favouring rapid clotting; if this tissue was deficient clotting was delayed or absent, and very profuse and prolonged hæmorrhage occurred which was liable to continue after the ovarian stimulus was withdrawn. Atrophy was often associated with chronic metritis and fibrosis uteri. Subinvolution, on the other hand, and true uterine hypertrophy, such as occurred in single women about the age of the menopause, were commonly combined with hypertrophy and œdema of the endometrium. The diagnosis of atrophy was confirmed by curettage; if with the curette small shreds of tissue only could be removed and the instrument came down immediately upon hard dense uterine wall, it could be concluded that atrophy was the cause of hæmorrhage. Mere curettage would not suffice to control the bleeding; and steps should be taken at the same sitting to control it permanently either by intra-uterine application of radium or by hysterectomy.

Radium in the Control of Uterine Hæmorrhage.

Radium was a very valuable agent for controlling uterine hæmorrhage due to ovarian and endometrial incoördination; he had so far been entirely satisfied with its effects. As far as the endometrium was concerned, radium appeared to produce atrophy both of glands and stroma, but especially of the former. Hence its great value in checking hæmorrhage due to hypertrophy. As regards the ovaries, radium appeared to destroy the Graafian follicles, but did not interfere with the stroma. This was a point of considerable interest, as it had a bearing, of course, upon the origin of the ovarian hormone.

With regard to hyperactivity, if sections were taken from various parts of a normal menstruating endometrium and examined under the microscope, it was found that all present practically the same appearance, both stroma and glands corresponding to the actual stage of the "period." On the other hand, if curettings are examined from some cases of metrostaxis or prolonged menstruation during active sexual life, it was found that all portions of the endometrium were not affected in the same manner at the same time. To this abnormality he thought the term hyperactivity might be applied; the term was only relative, as the endometrium was the reflector of activity of the ovarian and other hormones. In some cases of uterine hæmorrhage lasting from ten to 14 days the loss was often not severe, but the length of the period alarmed the patient; curettings from such a case showed that part of the endometrium was in the pre-menstrual stage and part in the post-menstrual. There had been a tendency to regard this appearance as a definite lesion of the endometrium, and to call it "endometritis," but there was no evidence of inflammation in the ordinary pathological sense of the word. Curettage would always give the clue to the cause of the bleeding if care were taken to examine several portions of the endometrium.

Endometritis as a Cause of Uterine Hæmorrhage.

In the older teaching much that was normal and a certain amount that was abnormal were grouped together under the term "endometritis." True endometritis—a definite inflammation of the endometrium set up by an infecting agent, bacterial or otherwise—was not so common as generally supposed, and was not necessarily associated with uterine hæmorrhage. The one cardinal symptom of true endometritis was the occurrence of a muco-purulent after drawing attention to the importance of distinguishing between radium emanations and the gas evolved from the element, described the technique he employed in treating cases of carcinoma too advanced for any radical operative treatment. A screen of silver, 1 mm. in thickness, was used. Seven tubes containing radium salt are employed and never less than 150 mg. for 24 hours were used. Fifty mg. of radium element were introduced well into the cervical canal under a general anæsthetic. Three other tubes, screened by brass and in the shape of stilets, were introduced into each broad ligament. The cervical tube was removed in 24 hours, but not the smaller tubes. The vagina was packed and douching employed daily after the removal of all tubes to keep the growth clear and to prevent vaginal adhesions. There is still some doubt as to the amount of radium that is actually necessary; but the results have been encouraging with the doses employed. Extremely advanced cases should not be touched. The prognosis appears to improve with the patient's age, the most unfavourable results being obtained in young patients. Involvement of the bladder is not a contra-indication. The best results are found naturally in those cases just past operability. Recurrences sometimes take as long as two years before appearance, and in one case where the opportunity occurred of examining the tissues post mortem six months after radium treatment, no microscopical recurrence could be detected. This was claimed as a cure. Dr. Burrows gave statistics of cases treated by his method dating from 1916 and covering a period of from 3 to 5 years. Two cases are alive and well 5 years after treatment. Six are well after 3 to 4½ years. Five were well 1 year after treatment but were then lost sight of. Six were rendered operable and radical operation was performed. Thirty-two were not cured but were made more comfortable. Twenty-six died quickly without any noticeable improvement. In other words, 6 per cent. of inoperable cases will probably be alive and well 4½ years after treatment, and 12 per cent. will probably live for 3 to 4 years after radium application.

Dr. W. ROBINSON said that if 12 per cent. of inoperable cases of carcinoma of the cervix were cured or relieved by radium treatment, the method should be adopted. He wondered if the cautery was of value in cases of advanced cervical disease. The results given by Burns in Kelly and Noble's "Gynæcology" seemed to challenge comparison with the extended hysterectomy performed to-day. Extension of uterine carcinoma appears to be by permeation, as not more than 30 per cent. of cases show glandular involvement post mortem.

Dr. CAMERON said that he had not had much experience in treating uterine carcinoma by radium, but it was surprising how rapidly superficial growths disappeared under treatment. He advocated very vigorous treatment, and the employment of from 250 to 350 mg. of radium bromide (150 to 200 mg. of element) at least. Such dosage had made inoperable cases operable. He was of opinion that the best results will be obtained by introducing the tubes directly into the tissues.

Mr. W. E. MILES (London) asked Dr. Burrows his grounds for deciding when a malignant cervix was inoperable. He was of opinion that it was impossible to tell unless the abdomen was opened. Because a uterus is somewhat fixed and a large growth present in the vagina the case is not necessarily inoperable. He thought that radium flattered for a time, but that eventually the growth recurred.

Mr. CECIL ROWNTREE (London) thought that Dr. Burrows was greatly to be congratulated upon the results which he had obtained, which almost equalled those of operative treatment. His experience had, however, been much the same as that of Mr. Ernest Miles, and he thought that although the growths shrunk for a time they were eventually attended by the usual fatal result.

Prof. A. DONALD (Manchester) said that he would like to confirm much that Dr. Burrows had said. As regards the cases described, they had been referred to Dr. Burrows by gynæcologists, and certainly they were inoperable.

Prof. KERR (Glasgow) said that he supported Prof. Donald in what he had said about inoperable cases being rendered operable by means of radium.

Mr. WHITEHOUSE asked if any instances of enteritis or colitis had followed Dr. Burrow's vigorous treatment. He believed that this had been the case with some observers, and certainly one fatal case had been recorded in the continental medical press. He congratulated Dr. Burrows upon the excellent results he had achieved in these inoperable cases.

The PRESIDENT said that his experience of radium therapy in uterine cancer was limited to ten or a dozen cases. The first two or three attempts had impressed him greatly and the growths disappeared as if by a charm. Recurrence occurred after six months. It was possible that if hysterectomy had been performed before recurrence was present, the lives of the patients might have been prolonged. He was convinced that we were working along the right lines, but perhaps we were not yet correct in our application.

Dr. BURROWS, in reply, said that large doses of radium should certainly be employed. He did not select cases himself. The question of operability rested with the surgeons who referred the cases to him. He had had no immediate ill-effects beyond one death from phlebitis amongst his earlier cases. This he attributed to sepsis and not to radium. Enteritis and colitis referred to by some writers had not occurred in his practice. Perhaps he had been fortunate.

FRIDAY, JULY 22ND.

NEURASTHENIC ELEMENT IN GYNÆCOLOGY.

Prof. A. DONALD (Manchester) in opening the discussion said that the subject was a difficult one to discuss on a scientific basis. Neurasthenia or nerve exhaustion was, of course, not limited to women. Cases of true neurasthenia and also hysteria were not often referred to the gynæcologist, but the neurotic woman with gynæcological symptoms was, on the other hand, a common type of patient. Only too often was she treated by the insertion of pessaries, specula, applications to the cervix, and so forth, and the speaker was of opinion that many neurotics were manufactured by such treatment. The periods of a woman's life when a nervous upset was most likely to appear were puberty, menstruation, and at the climacteric. Pregnancy, strangely enough, did not appear to be associated frequently with symptoms of nervous origin. Fear of the dangers and risks which pregnancy involves might reasonably be expected to produce in women symptoms akin to those that men exhibited in face of such stress as war. This in point of fact was not the case.

Prof. Donald then proceeded to discuss the value of certain symptoms and signs in relation to actual disease of the pelvic organs as distinguished from a pure neurosis. *Pain* is the commonest symptom of the neurotic, is generally referred to a wide area, and is unassociated with any organic basis. "Backache," if the only symptom present, is generally of nervous origin. Care must be taken, however, to eliminate such gynæcological causes for back-ache as pelvic peritonitis, metritis, chronic cervical catarrh, and rarely displacements of the uterus. So-called "ovarian pain," the speaker thought, was usually of nervous origin. The ovaries as a general rule do not cause pain. Prof. Donald also referred to right-sided abdominal pain often referred to the appendix. This organ at operation frequently appears to be normal in every way. Pain of a periodic character is usually dysmenorrhœal in type. The dysmenorrhœa of the neurotic, however, is never localised, never intense, and persists throughout the period. *Fatigue* is another symptom attributed frequently to neurasthenia. This may be the case, but it must not be overlooked that toxæmias, degenerating fibroids, and chronic metritis are often associated with profound fatigue. *Tenderness* on pressure, especially if general, is often due to neurosis. *Cutaneous hyperæsthesia* is not often marked, except as a cause of dyspareunia. The

Dr. Campbell, in reply, said that he would be very gratified if he could adopt the views expressed by Prof. Lyle. It would certainly save much trouble. He felt, however, that it was unfair to refuse a patient treatment unless she proclaimed her criminality to the world, and he wondered if the profession was justified in taking up such an attitude.

SECTION OF OPHTHALMOLOGY.

Wednesday, July 20th.

On the first day, Prof. J. D. Wardale, President of the Section, being in the chair, a discussion on the

Causes and Prevention of Blindness

was opened by Mr. N. Bishop Harman (London), based on an analysis of 4288 cases. Mr. Harman's figures came from three sources: (1) a home for blind infants, (2) L.C.C. schools and classes, (3) private case-books. In group 1 the conditions are as follows: out of a total of 63 blind infants, ophthalmia neonatorum is the determining cause in 31; congenital defects account for 19; while the remaining 13 are the result of a variety of diseases. The L.C.C. "myope classes" and schools for the blind (group 2) have furnished in the past 17 years 3300 cases of blind and partly-sighted children. It is not practicable to reproduce in full Mr. Harman's tables, in which he carefully analyses the causes operating to produce blindness or defective vision. Ophthalmia neonatorum is found to account for 299 blind and 68 partly-sighted—a total of 367; interstitial keratitis, due to congenital syphilis, for 362; and interstitial keratitis, in which the evidence of syphilis is not certain, accounts for 24; while disseminated choroiditis of syphilitic origin obtains in 210, together with 19 more in which the evidence of syphilis is not quite complete. This, however, is not the whole tale of syphilis. It appears as a causative agent also in buphthalmia or congenital glaucoma; in defects of the macula; in retinitis pigmentosa; and in irido-cyclitis. Cases of high myopia number 1235. Mr. Harman classifies them according to the mean of the four meridians of the two eyes. The method has obvious disadvantages, as Mr. Harman points out, but a less faulty substitute is difficult to devise. Group 3 consists of persons of all ages met with in private practice, and contains 925 persons. Cataract accounts for 94, and high myopia for 84 cases. Diseases of the uveal tract—iritis, irido-cyclitis, and choroiditis—are responsible for 133 cases; glaucoma for 55; and corneal diseases for 51. In this all-age group the syphilitic cases form the largest section of preventable disease—85, or 9·19 per cent. of the gross total. In infancy congenital defects and purulent conjunctivitis account for nearly all the blindness; amongst school children cases due to congenital syphilis hold first place; but in the all-age group the greater variety of causes operating, many of which mainly or only affect adults, lowers considerably the percentage of cases of blindness for which venereal diseases are responsible. From these returns it is correct to state that 50 per cent. of the blindness of *infancy* is due to ophthalmia neonatorum; that 50 per cent. of the blindness in *school children* is due to parental venereal disease; but the true figures for "*all ages*" are seen to be 2·5 per cent. from gonorrhœa and 9 per cent. from syphilis.

Mr. Harman then discussed prevention. For ophthalmia neonatorum he suggests treatment of the expectant mother combined with, in each convenient area, a mobile unit that could be rushed to every notified case after the manner of a fire brigade.

Dr. J. A. Wilson (Glasgow) considered Mr. Harman's figures not sufficient to gauge the causes of blindness in the general population, and alluded to the results of the inquiry of the Local Government Board in Scotland. He laid stress on the factor of heredity in myopia, and on the importance of seriously grappling with the problem of venereal disease prevention.

Mr. E. H. E. Stack (Bristol) pointed out that there was at present no method available of tackling amblyopia exanopsia. The school age was too late. To get binocular vision treatment should be begun at 3 or 4 years. He recalled that Symes, of Bristol, had drawn attention to the association of phlyctenular keratitis with erythema nodosum. He considered recurrent irido-cyclitis as the most troublesome of all his cases. He agreed with Mr. Harman that goggles should be worn more often by workmen as a protection against accidents, and suggested that light celluloid ones would be more comfortable.

Mr. A. S. Percival (Newcastle-on-Tyne) gave a simple method of preventing steaming of goggles—viz., rubbing the glass well with dry soap and polishing it afterwards. He also showed the tests that he now uses for determining light-sense, and states that the condition of the macula can be satisfactorily ascertained even in cases of cataract, in which the fundus cannot be directly examined. Thus it is possible to prevent the tragedy of a successful cataract extraction, but no resulting improvement in vision owing to Tay's choroiditis or other unsuspected macular condition. An account of his demonstration is given below.

Dr. H. Scurfield (late M.O.H., Sheffield) said that he was interested in ophthalmia neonatorum prevention from the point of view of a medical officer of health. He called attention to Dr. Janet Campbell's statement that ophthalmia neonatorum occurs in nearly 1 per cent. of births in lying-in institutions run by local authorities, and he strongly recommended the appointment of an ophthalmic surgeon to every lying-in hospital. He raised the point—would early skilled treatment always prevent blindness?

Dr. G. Foggin (Newcastle) pointed out that the success of the Créde method depended on the routine disinfection of every eye, and he suggested an association of general practitioners and obstetricians pledged never to attend a birth without disinfecting the baby's eyes. He also deprecated the apathy of education authorities regarding the provision of myope classes.

Mr. W. B. Inglis Pollock (Glasgow) emphasised the amount of preventable blindness due to glaucoma being frequently wrongly diagnosed as cataract.

Mr. J. V. Paterson (Edinburgh) has seen very few cases of ophthalmia neonatorum in private practice during the past 20 years, although he has had many severe cases in hospital practice. He points out how much more serious blindness in youth is than blindness in old age. He considers many lamellar cataracts to be due to syphilis, and that Tay's choroiditis is often progressive, the macular affection later involving the periphery.

Dr. Marion Gilchrist (Glasgow) states that trachoma is very common in Glasgow, possibly owing to a large population of Polish Jews, and preventive measures are urgently required. She emphasised the importance of very careful refraction work in myopia, and said that the prevention of blindness was bound up with the prevention of venereal disease.

Mr. Harman, in replying, said that, apart from the possibility of subsequent blindness, the closing of the eyes for the first three weeks of life on account of ophthalmia neonatorum often leads to non-development of the macula and nystagmus.

Early Operation in Squint.

Mr. Pollock read a paper similar in substance to that which appeared in The Lancet of June 18th.

Prof. Wardale considered occlusion of the good eye theoretically excellent but difficult to get done in practice.

Mr. Stack thought that after occlusion for even one month it is possible to tell whether or no there will be improvement in vision. He pointed out also how a man's prospects in life are improved by straightening a squint.

Mr. Pollock, in his reply, said that he practised tenotomy only in cases of 40° to 45°, and then incompletely and far back from the cornea.

Light-Sense Test.

Mr. Percival gave a demonstration of his light-sense test. This consists of two cardboard discs 9 cm. in diameter, one surface of each being blackened.

Discussion.

Dr. **WILLIAM ROBINSON** (Sunderland) agreed with the views put forward by Prof. Donald. Many diseases previously thought to be neurotic in character—e.g., paralysis agitans—had now been proved to be organic, and it was possible that in the case of hysteria some organic change will eventually be discovered. He hoped that in the future more would be heard of the relationship between neurasthenia and the endocrine glands, and instanced the association of some nervous prostration in Addison's disease and excessive fear in hypothyroidism.

Dr. **R. H. PARAMORE** (Rugby) called attention to the influence of intra-abdominal pressure upon neurasthenia. He did not think that the latter was entirely due to a disorder of mind. Many diseases he was of opinion could only be explained mechanically and were due to diminished pressure. If the heart did not receive sufficient blood the brain would not be nourished. Treatment by rest and abdominal support, he thought, confirmed his views. Dr. Paramore asked if neurasthenia ever occurred during pregnancy. If this was the case it would negative the views he had expressed.

Dr. **HELEN BOYLE** (Brighton) thought that a great difficulty existed in actually defining neurasthenia. Dr. Buzzard's definition was perhaps too wide to be practicable, and she suggested as an alternative the two words "weak nerves." Dr. Boyle asked the opinion of the meeting on the advisability of stopping lactation in the case of a patient exhibiting nervous symptoms. As a general rule, she thought that stopping lactation rather aggravated neurasthenia. She also drew attention to recurring attacks of neurasthenia at menstrual epochs and as a post-operative sequela. Suicidal tendencies may become manifest at the menstrual periods if depression is profound.

Dr. **R. J. JOHNSTONE** (Belfast) wondered if neurasthenia was due largely to lack of occupation. It was certainly more common in the better-class type of patient and must be distinguished from the nervous exhaustion of the poorer classes. Neurasthenia is a general lowering of tone of the whole organism, especially of the neuro-muscular system. For this reason he did not quite agree with the definition which limited it entirely to the nervous system. Dr. Johnstone entered a protest against the practice of fixation of the uterus in the "nervous" type of patient. He also deprecated the custom of attributing pelvic pain so frequently to the ovaries. If the ovaries were as easily examined as the testicles he was of opinion that much less would be heard of "ovarian pain." The mental shock consequent upon an operation is a factor which must not be overlooked as a cause of neurasthenia, and patients should, he thought, be treated as invalids for six months after a severe operation. A bad confinement in the patient's sense of the term falls under the same heading, and for this reason the early use of forceps and chloroform as soon as the os is sufficiently dilated is to be recommended. Dr. Johnstone did not agree with Prof. Donald's remarks regarding the use of specula and applications to the cervix. He thought that many patients were improved, if not actually cured, by "consulting-room treatment."

Dr. **MARY STURGE** (Birmingham) recorded a case of dysmenorrhœa in which nephropexy had been performed, and in her opinion the case had been cured by the operation. Symptoms associated with retroflexion of the uterus were also, from her point of view, often cured by replacement of the uterus by means of a pessary.

Dr. **F. BELL** (Humshaugh) concurred with Dr. Johnstone in the opinion that much of the neurasthenia in women is the result of fear and pain of labour. The early use of chloroform and forceps, and the employment of scopolamine-morphine narcosis will do much to remove it. The employment of midwives, on the other hand, must tend to increase neurasthenia from this cause.

Prof. **RANKEN LYLE** (Newcastle-on-Tyne) moved a cordial vote of thanks to Prof. Donald and Dr. Farquhar Buzzard for their valuable opening papers. The object of the discussion had been to differentiate as far as possible between the physical and the nervous in gynæcology and to define a limit between operative and minor treatment. Twenty years ago minor treatment, such as cauterisation of the cervix, the introduction of pessaries, &c., had a great vogue. It was followed by an era of endless minor operations such as Alexander's operation for backward displacement of the uterus. What was required now was to adjust a proper balance between these two schools. Concerning the points raised by various speakers, he was of opinion that pain in the iliac fossæ is of intestinal origin in all cases and may be verified by the administration of a bismuth meal. In 48 hours the meal will have reached the cæcum and pain will be present. Many of the symptoms in the so-called neurotic patient were actually hallucinations or delusions and, as Dr. Buzzard had said, had a basis in fear.

Prof. **DONALD**, in reply, was in favour of stopping lactation in cases where nervous symptoms were severe. If nervous manifestations follow a surgical operation, he thought that it was usually due to an error of judgment on the part of the surgeon in performing the operation at all. Operations *may* be necessary in patients with the neurotic taint, but should be avoided if possible. With regard to iliac pain, he was of opinion that it was not intestinal in origin but due to some uterine lesion.

Dr. **BUZZARD** said that he was glad exception had been taken to his definition of neurasthenia. It was a good thing that no definition could be found, as it only tended to narrow one's outlook. What we wanted was to widen it. Dr. Sturge had met with a case of cure following nephropexy and thought it wonderful. Of course it occurred. Everybody knew it and naturally there were many such cases. At the same time it did not alter the fundamental principles which he had tried to explain.

Mr. **BECKWITH WHITEHOUSE** (Birmingham) read a paper on

CURETTAGE AND THE TREATMENT OF UTERINE HÆMORRHAGE,

in which he expressed the wish to focus attention upon a few of those conditions where hæmorrhage was an important symptom, and where some difficulty arose in assigning a cause even after curettage had been performed; the problems introduced by pregnancy opened up a field too large for the present discussion. The problems of diagnosis and treatment were greatest in cases where gross physical signs were absent, and where the type of hæmorrhage might almost be termed functional. He had made an inquiry into the subject and had published his results in 1914[1]; since that date additional facts had been forthcoming,[2] but hitherto he had had no reason to alter the opinions then expressed. He regarded the menstrual function in the human female as analogous to the pro-œstrum of animals; it consisted of the products of digestion of minute coagula formed in the endometrium and uterine cavity, and mixed with secretion of the uterine glands. Under normal conditions hæmorrhage from the menstruating endometrium was a slow ooze, there being ample time for the blood to be brought into relation with the stroma cells which contain the thrombotic elements and the secretion of the uterine glands which effected thrombolysis.

The Menstrual Theory.

There was little doubt that the ovary was the prime factor in the production of menstrual hæmorrhage. Evidence was accumulating to show that the endometrium must be regarded as a ductless gland producing its own hormone and having a specific action upon the sexual economy. It was intimately tension be up he does paracentesis and treats ulcers associated with acne rosacea with magnesium sulphate lotion.

---

[1] THE LANCET, Hunterian lecture, 1914, i., 877, 951.

[2] Practitioner's Encyclopædia of Gynæcology, 1921, edited by J. S. Fairbairn, Oxford Med. Publ.

Mr. Paterson replied, pointing out that the value of paracentesis lay in its replacing stale aqueous by fresh fluid rich in antibodies. The reduction of increased tension is important, as the hard cornea sloughs more readily. He considers that antiseptics on mucous membranes are of very little use; their sole value is the reaction they produce. Ulcers with yellow, deeply infiltrated margins need powerful chemical or physical agents. He gives internal drugs very little, and is sceptical of their value, but attention to diet is very important.

Short Papers.

Dr. J. A. Wilson (Glasgow) read a paper on Auto-intoxication in Ophthalmology. Sir Arbuthnot Lane has stated that in cases of intestinal toxæmia the eyes are always affected. In all bacteriæmias the synovial membranes, serous membranes, conjunctivæ, ciliary bodies, and iris become not so much secretory as excretory structures, and long ago Mr. Sydney Stephenson had suggested that toxins were excreted by the ciliary bodies. Dr. Wilson gave several instances of eye disease due to toxæmias arising from suppuration in joints, wounds, &c., and considers most non-suppurative, post-operative failures after cataract extraction to be endogenous in origin. Loss of accommodation due to toxæmia is not uncommon. He draws attention to the importance of studying eye conditions from the point of view of general medicine and approves of Dr. Rayner Batten's suggestion that ophthalmic physicians, as well as ophthalmic surgeons, should be appointed to the staff of every eye hospital.

Mr. E. C. Moore (Gateshead) described a case of Chronic Irido-cyclitis due to Gonorrhœa.

Mr. Percival described a case of Irido-cyclitis Associated with Stricture of the Urethra, which improved within three days after the operation of internal urethrotomy. He suggested the application of radiant heat as a diagnostic test before operating on suspicious cases. Reaction, as indicated by persistent redness, probably denotes occluded sepsis. The application should be repeated until no reaction appears, and then the case is safe to operate upon.

Dr. Traquair considers the difficult cases to be not those associated with venereal disease, but those arising from obscure infections. Morax regards all post-operative infections as exogenous, and keratitis punctata always indicates the presence of micro-organisms within the eye. The fact that one eye only is affected as a rule lends further support to the theory of exogenous origin.

Dr. A. MacRae (Corbridge-on-Tyne) read a paper on Nodular Keratitis of Southern Arabia. This condition is found chiefly in males of middle age or older. A group of nodules is present in the centre of the cornea or its lower half. The nodules are transparent, glassy, covered with normal epithelium, and set close together. There is no opacity, no vascularisation of the cornea or limbus, and the other ocular tissues are healthy or, if diseased, have no causal relationship to the corneal condition. The nodules vary in size; the largest is about 1 mm. in diameter, and projects about the same amount. In a few cases the cornea may be opaque or stain faintly in between the nodules. The group covers a roughly circular or oval area, but a ring form bounding a clear or opaque centre is also found. Dr. MacRae has found this condition in Somalis, Arabs, and Sudanese, whose work is on or by the sea. He has not found it among the inhabitants of the interior. He suggests that the salt-laden winds of the low-lying coast-land is a factor in its causation. The sand is impregnated with minute particles of salt, and is always being blown about in the coastal area. He thinks this condition is found in about one or two of every 200 cases of eye disease seen. Vision is affected considerably, and is better at night.

Reviews and Notices of Books.

The Psychology of Day-dreams.

By Dr. J. Varendonck, formerly Lecturer in the Paidological Faculty of Brussels. London: George Allen and Unwin. 1921. Pp. 367. 18*s*.

Whilst serving as interpreter at the front Dr. Varendonck became acquainted with Freud's writings, and, being already a practical psychologist, turned his attention to the study of his own day-dreams. The day-dream is not, in his usage of the word, the conscious musing which we call "building castles in the air," but is rather the work of that "fore-conscious" which lies just beneath consciousness, and may influence at any moment our thoughts and actions without our being aware of the processes concerned. All transitions are found, "from the fancy of the boy, who, riding his hobby-horse, plays the part of a general, or the poet who abreacts his unhappy passions in a work of art, or changes it into requited love, to the obscure hysterical sufferer or the schizophrenic." The author has trained his power of seizing upon the last link in the day-dream, whether it occurs during distraction or between sleeping and waking, and of following back the links in the chain so as to reconstruct the whole phantasy. This, being a subjective process, can only be fully understood by experience. Dr. Varendonck, after training himself to recall and record his day-dreams, has studied them by the methods that introspective psychologists have applied to conscious mental processes.

Professor Freud, to whose "Psychopathology of every-day Life" and "Interpretation of Dreams" Dr. Varendonck makes frequent reference, writes a short introduction indicating the importance of the work and its results, though he criticises the use of the phrase "fore-conscious thinking," and would prefer to speak of "freely wandering or phantastic thinking" in contrast to the intentionally directed reflection of our conscious life.

In the first half of the book the process of fore-conscious thinking is analysed: it may proceed by recollections, in which one memory recalls another, and each memory is associated with its own affect (i.e., its own emotional tone); in this type the dream is almost entirely visual, and the dreamer is rather a passive spectator than the actor. In a second type the dream is activated by a wish, and then the pictures are used as illustrations of a theme; the affect is associated more with an idea than with a memory, so that, for example, the recollection of being in a shelled village arouses no horror, though a feeling of interest is continually maintained; the "inner self" is too busy with acting to heed the spectacle. The pictures are not pure recollections, but new creations, which, on analysis, are found to be attempts to solve a problem, each new part being a new proposition, a new question, or a new answer. This type provides examples of creative thought directed by affect. Fore-conscious or affective thinking is able to draw upon memories in a way impossible to consciousness; its inventive faculties are active, and, whereas conscious thought involves the use of energy to exclude ideas judged irrelevant or distasteful, the fore-conscious is under no such restraint, and knows no ethical standard. The author frankly illustrates this by a day-dream in which he loses both legs through a shell explosion; this he does not recognise, until a fortnight later, as being activated by a wish to return to civil life and seek a professorial chair. His psychological blindness to this interpretation, which is a fairly obvious one to the psycho-analyst, is identical with the blindness of the hysteric to his own unconscious motives even when they are obvious to the onlooker. One asks—in all seriousness and with a knowledge that the answer would be valuable—why Dr. Varendonck did not develop a hysterical paraplegia.

or purulent discharge. Glandular and atrophic endometritis, as such, did not exist. In 50 cases classed clinically as endometritis by different observers, in which he had examined the curetted material, the following results were obtained: 33 patients gave a history of menorrhagia or menostaxis; 17 gave a history of metrostaxis; 31 showed hypertrophy of endometrium, especially of the glandular elements; 12 showed atrophy of endometrium, with diminution of both glands and stroma; 7 showed marked leucocytic infiltration and plasma cells. In other words, 43 exhibited evidence of those changes which recent investigation had shown to be due to many factors other than inflammation. Endometritis of septic origin did not appear to produce uterine hæmorrhage, with one or two exceptions.

Value of Curettage.

On previous occasions he had more than once entered a protest against the practice of indiscriminate curetting for all cases of obscure uterine hæmorrhage. The operation might do good, but the chances were equally against it if the cause of bleeding was not directly dependent upon pregnancy. As a diagnostic procedure, however, curettage was of paramount importance, especially when the microscopical appearances of the endometrium were considered in relation *to the history of the case and the character of the uterine* discharge. No report was of value unless submitted by a pathologist conversant with gynæcological pathology, and especially with the endometrium in all its phases. As a therapeutic measure, curettage for uterine hæmorrhage depended upon the cause of bleeding. If the latter was due entirely to the uterus, it might be curative; if it was the result of incoördination of various hormones, curettage would be only palliative, or would fail completely. Treatment, to be effective, must depend upon accurate diagnosis. Much disappointment and failure had resulted from reliance upon empirical methods.

Discussion.

Dr. JOHNSTONE expressed his appreciation of the paper and was much interested in the facts that had been brought forward. Mr. Whitehouse had broken a lot of new ground and the paper was one which required careful consideration at leisure.

Dr. W. R. GROVE (St. Ives, Hunts) thought that Mr. Whitehouse was correct in the views that he had expressed, especially as to the rôle that calcium played in the production of normal and abnormal uterine hæmorrhage. He referred to a paper which Dr. Vines and he had read before the Section of Therapeutics upon the relationship which the calcium metabolism had to varicose ulcers. Calcium salts when administered by mouth were not absorbed and practically the whole was recoverable from the fæces. A calcium deficient may, however, be cured by the administration daily of parathyroid (Burroughs, Wellcome and Co.) in doses of one-tenth of a grain. The calcium index becomes normal in the space of one week under this treatment. Thyroid gland itself did not in his experiments appear to have any influence upon the calcium metabolism. Symptomatic hæmorrhage can frequently be relieved by increasing the coagulability of the blood by the injection of calcium chloride into the gluteal muscles in doses of one grain of the salt dissolved in 4 minims of water.

Mr. GORDON LEY was in entire agreement with what Mr. Whitehouse had said, apart from the influence that the ovary had in maintaining menstrual hæmorrhage. He knew of at least half a dozen cases where uterine bleeding had persisted after removal of both ovaries, and did not think that these cases could be explained on the basis that ovarian tissue had been left at the time of operation. He wondered what was the explanation at the root of such cases.

Prof. LYLE expressed the thanks of the Section to Mr. Whitehouse for his valuable contribution to the work of the Section. Like Dr. Johnstone, he would require time to consider all the facts that Mr. Whitehouse had brought forward upon his subject.

POSITION OF THE MEDICAL PRACTITIONER IN CASES OF PROCURED ABORTION.

Dr. JOHN CAMPBELL (Belfast) read a paper upon the position of the medical practitioner called in to attend a case of procured abortion. He said that a doctor in such cases occupies a dual rôle. He has a duty to perform as a citizen in preventing crime in the interest of the community. He also as a doctor must preserve the secrets of his patient. If a patient did not divulge all the facts to her doctor such reticence might be a grave disadvantage to her. On the other hand, it placed the doctor in a difficult position, as he had to choose between his duty as a citizen and his obligation to his patient. When an illegal operation is contemplated a doctor can do nothing, but he thus becomes unwillingly an accessory to the crime. Dr. Campbell gave details of an instance of this kind occurring in his own practice, which very forcibly had brought the matter under his notice. Frequently the performance of an illegal operation is only discovered when a patient in extremis from either hæmorrhage or sepsis divulges the true facts. Under such circumstances he thought that a doctor must honour the confidence of his patient. Should death occur the doctor's obligation ceases and he is at liberty to expose the knowledge previously placed in his hands. The conclusions at which he had arrived were that a doctor must remain silent when an illegal operation is projected or when it has been done, when such knowledge is brought to him in the course of his professional capacity. After death, on the other hand, this obligation ceases. Dr. Campbell was of opinion that in the present position of British law a grave discrepancy existed, in that the abortionist is held to be solely responsible for the crime and punished accordingly, whereas the individuals who introduce the patient for an illegal operation are generally allowed to escape "scot-free," although being the prime movers in the affair.

Dr. W. ROBINSON said that all induced abortions, whether produced by drugs or instruments, were criminal. He did not consider it a doctor's duty to inform the police when such an abortion was produced by the patient herself. In the case of a single girl where an illegal operation had been done, it was a practitioner's duty to inform the parents or a responsible individual as to what had been done. He could recall several instances, however, where information of an illegal operation had been given, in one case to the Home Office, and no steps had been taken. In the case of information demanded by one of His Majesty's judges in court he was of opinion that facts must be divulged. After all it is only custom that has prevented a medical man from not telling, just as it is custom in the case of a Roman Catholic priest. In a court of law custom falls to the ground and a doctor must tell all he knows when asked by a judge.

Dr. J. D. DAVIES (Llanelly) thought that a doctor would be fully justified in giving information of a projected illegal operation and that he is not justified in becoming an accessory to a crime.

Dr. MORRIS (Cardiff) said that the question raised was a very large one, as probably 80 per cent. of the abortions in all married women are induced and so are criminal.

Prof. LYLE differed from the writer of the paper in the views that he had expressed. The duty of a doctor above all things was to guard his own reputation. For this reason he personally would not treat or have anything to do with such a case, unless the patient gave him permission to inform the police. By this refusal suspicion can never be cast upon a medical man. He should, in other words, take every step not to be involved in cases of this type. Only too often the abortionist does the operation and then transfers the case to a doctor. The medical man really therefore works in collusion with the abortionist. In Newcastle they were in the fortunate position that the practice he had advocated was universal. The result was that the abortionist in Newcastle knew that he could never receive any help from the medical profession, and such cases were never encountered.

LA MÉDECINE.

By G. H. ROGER. Paris: Masson and Co. 1920. Pp. 400. Fr.10.

THIS study of the principles of medicine from the standpoint of general biology is opportune, for amid a multitude of detail our conception of medicine as a whole is apt to become confused. The author starts from the text that every vital manifestation, psychic or somatic, normal or pathological, is simply a reaction, immediate or delayed, provoked by an external agent. He describes the evolution of medical science as occurring in three phases—the period of clinical observation, the anatomical period, and the biological period. This is particularly well seen in the history of nervous diseases, and is illustrated by the way that "locomotor ataxy" became "tabes dorsalis" and was finally attributed to a specific parenchymatous degeneration of the lower sensory neuron. His conception of the reaction of the body to disease may be paraphrased thus—an attempt is made to find a new position of equilibrium, which, however, is an inferior one, where the vital processes work with more friction. For if the new position were a better one than that existing in health it would tend to replace it in evolution and to become the normal. Though open to criticism in points of detail, throughout the book the outlook is broad, the exposition lucid, and the grasp of general principles maintained.

X RAY DIAGNOSIS AND THERAPY.

Roentgen Interpretation. A Manual for Students and Practitioners. Second edition. By G. W. HOLMES, M.D., and H. E. RUGGLES, M.D. London: Henry Kimpton. 1921. Pp. 228. 18s.

THAT a rather specialised volume such as this should have reached a second edition within two years shows the steadily increasing desire on the part of medical men for further knowledge and understanding of X ray appearances. It was our pleasure to welcome and recommend the first edition, from which the present one differs in no essential particular. The only changes appear to be the correction of minor errors, the omission of a few illustrations, and the addition of several others. These, with some alteration and rearrangement of the text, improve the volume.

As in most radiological publications at the present time, many of the reproductions of radiographs leave something to be desired. Possibly the collotype reproduction of a smaller number of carefully selected radiographs, and the more free use of diagrams, would enhance the value of the illustrations while keeping the cost of production within practicable limits.

Dosierungstafeln für die Röntgentherapie. By FRIEDRICH VOLTZ, Dr. Phil., Physical Assistant, Radiological Section, University of Munich Gynæcological Clinic. Munich: J. F. Lehmann. 1921. Pp. 94. 5s. 7d.

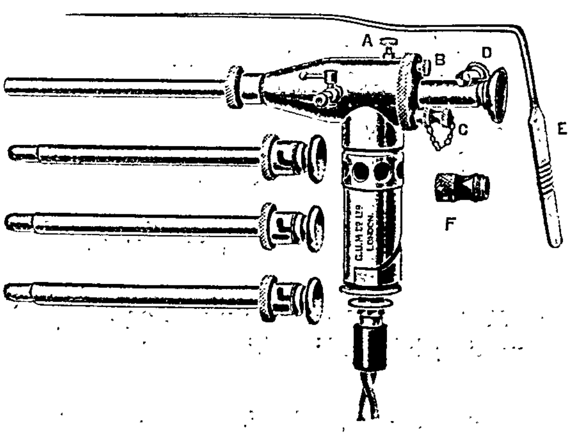
THE author has prepared these tables as a result of a large number of exact measurements and calculations, with the object of enabling a correct dosage in practical X ray work to be obtained without arduous repetition of measurements and calculations in each special case. The tables are based on the Seitz-Wintz system of biological measurement, using X rays filtered through 0·5 mm. of zinc, but they can be used with other systems having a dosage calculated on an exact physical and biological basis. The tables are divided into three groups—(1) dispersion, time and distance factors affecting intensity; (2) absorption, and field activity as influenced by the area irradiated; and (3) appropriate dosage for certain specified conditions. A knowledge of certain physical laws is taken for granted and explanations are given in a form readily understood. If these tables are studied and used by radiologists they will do much to put the subject of X ray dosage on a more scientific and satisfactory basis. A translation is apparently being prepared and will be available at an early date.

New Inventions.

A NEW AERO-URETHROSCOPE.

THIS urethroscope is an improved model of the one I introduced in 1914 (vide THE LANCET, Jan. 10th, p. 114); but the modifications now introduced are numerous and important.

The urethroscope proper consists of two tubes, fixed at right angles to each other, in the form of an inverted letter L (⅂). The vertical limb carries the lamp holder in its lower part, and a bull's eye condenser just below its junction with the horizontal limb. The lamp holder is a short cylindrical fitting, carrying the lamp on its upper and the "flex" from the battery on its lower end. It fits lightly within the vertical tube, and its motion is controlled by a stud which engages in a spiral slot cut in the wall of the tube. This allows the lamp holder to be instantaneously withdrawn for the purpose of inspecting or changing the bulb, and ample play is given for focussing the beam of light. Ventilation is provided just below the position of the condenser to enable the heat generated by the electric bulb to be quickly dissipated. The horizontal tube is tapered to its attachment with the urethral cannula, while its opposite end is closed by means of the "end-plate." It also carries the tap by which air is admitted to distend the urethra.



The end-plate is a flat plate of brass, surrounded by a deep collar, which is threaded internally, and is screwed on to an external thread cut on the horizontal tube. The inner surface of this plate carries a framework which supports the inclined mirror, while its centre is pierced by a hole 1 cm. in diameter. Into this hole the telescope (D) or the plain eye-piece (F) is screwed. The mirror is adjustable both in a vertical and in a horizontal direction; this is necessary because the filaments in the electric bulbs are rarely absolutely central. Vertical movement of the mirror is effected by turning the milled head (B), while horizontal rotation is obtained by loosening the clamping screw (A) and rotating the whole end-plate. The telescope is of the Galilean type, giving a magnification of 2½ diameters.

The operating attachment has been completely re-designed in this instrument. Below the telescope a small nipple (C) projects through the end-plate. This is covered by a perforated screw cap. Between the nipple and the cap is a rubber washer, and the tighter the cap is screwed down, the more the washer is compressed. Usually the hole in the cap is plugged by a metal pin, attached to the urethroscope by means of a chain. When operating, the pin is removed and the instrument is inserted through the hole. It passes below the mirror, the lower part of which is cut away. The shank of the instrument is grasped sufficiently tightly by the rubber washer to prevent air leaking past. This arrangement is similar to that used in catheterising cystoscopes for preventing water leakage along the side of the ureteric catheters. By this means minor operations can easily be carried out under air distension. At present I only use two instruments when operating through this urethroscope, a probe (E) and an electrolysis needle.

The urethroscope, including the telescope, has been made for me by the Genito-Urinary Manufacturing Co., 66, Margaret-street, London, W.

Wimpole-street, W. J. SWIFT JOLY, F.R.C.S. Eng.

On the white surface of one disc sectors of black 1 cm. long are marked, that nearest the centre representing in area 0·08 of the inner ring, the next 0·04 of the intermediate ring, and the outer 0·02 of the outer ring. On rotating the disc on a dissecting needle, three grey rings are seen on a white ground. If the patient sees all three rings his L.D. must be at least 0·02. On the blackened surface there are three similar white sectors, so that on rotation three dark-grey rings are seen. If the patient sees all three his L.M. must be at least 0·02. On the other cardboard disc the sectors are smaller, so that, when rotated, the inner ring denotes an L.D. of 1/50, the intermediate 1/100, and the outer 1/200.

THURSDAY, JULY 21ST.

Treatment of Corneal Ulcers.

The discussion was opened by Mr. PATERSON with some preliminary remarks on the structure and nutrition of the cornea and their influence on the peculiarities of corneal ulceration, after which he considered ulcers under two headings: (*a*) those in which the cause comes from without; (*b*) ulcers in which the state of the patient's health is the main factor. Taking the hypopyon ulcer as a type of class (*a*), he insisted upon the importance of early hospital treatment. The state of the tear passages should be carefully investigated and, in elderly patients particularly, the intra-ocular tension. Early cases readily respond to neutral saline bathing, atropine drops twice a day, and a silver salt such as argyrol, 20 per cent., thrice a day. The eye is never covered with any sort of dressing or shade at this stage, but a little sterile vaseline is applied to the lid margins. If the ulcer be progressing at the end of 24 to 48 hours it is touched with pure carbolic, well rubbed into the spreading margin, or even cauterised if it looks unduly threatening. Mr. Paterson generally uses the hand cautery and makes every application under a stereoscopic magnifier. If the ulcer be spreading actively, and associated with hypopyon when seen for the first time, it is immediately cauterised and the hypopyon afterwards evacuated by paracentesis from below. Mr. Paterson considers the Saemisch section very effective when the cautery has failed to check the spread of the ulcer, particularly in cases of small ulcers with a very purulent infiltration extending deeply into the corneal substance. He further often combines cauterisation with heat obtained by holding the cautery very close to less infiltrated parts of the ulcer. A small proportion of ulcers, generally found in old and somewhat feeble patients, apparently resist all treatment. On the whole, Mr. Paterson prefers the Saemisch section, though it, too, may fail. In Edinburgh it is the custom to leave eyes uncovered until the ulcer clears and re-infection is no longer to be feared. Then a pressure bandage may be useful, especially in cases of perforation with leakage from the anterior chamber. The chief complication in cases where there has been widespread corneal destruction is increased tension and staphyloma. Iridectomy is only of moderate value in reducing the tension in these cases, but trephining has given better results. In hypopyon ulcer in children Mr. Paterson has never used the cautery or carbolic. Atropine and the good hygiene and diet of a hospital ward are usually sufficient.

With regard to class (*b*), Mr. Paterson thinks strumous ulcer of the cornea much less common now than 20 years ago, and only a small fraction are of a really severe type. If the symptoms be acute the children are kept in bed, given a simple purgative, and put on small doses of grey powder or calomel. The chief error of diet seems to be an excess of starchy foods. Atropine is used locally and later in combination with dilute yellow oxide of mercury ointment. He seldom has recourse to tuberculin or other vaccine treatment, but has found it valuable in obstinate cases. Very often surgical treatment of tonsils or tuberculous glands is necessary. Herpetic ulcer of the cornea is treated by the application of absolute alcohol, followed by atropine and a bandage. This treatment is satisfactory also in the case of dendriform ulcer, but should always be made in a fairly drastic fashion. Mooren's ulcer often resists treatment of any sort, and the same is also true of the superficial recurring ulcer associated with rosacea of the face.

Dr. H. M. TRAQUAIR (Edinburgh), who has had considerable experience in the treatment of corneal conditions by ionisation, described the methods he has used. With a galvanometer current of ½ to 1 milliamperes and solid zinc electrodes he has had good results in the milder forms of severe ulceration, but in the very severe cases his results were not better than by other means. He emphasised the importance of fresh air and sunlight in the treatment of the strumous ulcers of children.

Mr. PERCIVAL spoke of the value of quinine drops in hypopyon ulcer. He uses a solution of the bihydrochloride of quinine (gr. viii.–℥i.), usually combined with atropine. The quinine treatment should be continued for at least one week after the cessation of the hypopyon. He pointed out that quinine solution goes through Descemet's membrane and quinine fluorescence can be demonstrated in the anterior chamber. He considers that there is danger of infecting a sterile hypopyon by doing a paracentesis where there has been no perforation.

Dr. D. M. MACKAY (Hull) thought carbolic had no bad permanent effect on healthy cornea, and that it was preferable to the cautery. He uses magnesium sulphate in saturated solution as a fomentation, and is satisfied with the results.

Mr. HARMAN was struck with the recommendation for open treatment, and quoted some Dutch experiments which went to show that the reparative powers of the avascular cornea are at their maximum under the influence of warmth. He thinks silver weakens tissue resistance, and uses hydrogen peroxide. He regards the actual cautery as too destructive, and uses instead phenol-camphor (phenol and camphor equal parts). He uses the cautery, however, to destroy the leash of vessels at the limbus in phlyctenular ulceration—a modified peritomy. He pointed out that Guthrie of Liverpool originated section of the ulcer now associated with the name of Saemisch.

Dr. N. B. B. FLEMING (London) recommended in sloughy ulcers five minutes' immersion in an eye-bath of magnesium sulphate lotion, and the subconjunctival injection of colloidal iodine in wound infections where the ulcer is situated near the limbus.

Mr. T. L. DE COURCY (Liverpool) spoke of the value of stock vaccines of conjunctival organisms in marasmic children. The cautery used close to the cornea, but not in contact with it, gave good results. Dionine, up to 5 per cent., combined with atropine, was useful; the results depend on the amount of reaction.

Mr. J. HERN (Darlington) referred to the treatment of a chronic form of ulcer with a clear base, common in middle age and tending to recur each spring after the depression of winter. He stitches up the lids and keeps the patient in bed. He has a high opinion of the value of the Saemisch section and uses 25 per cent. argyrol in septic cases.

Prof. WARDALE thought that the only virtue argyrol had was that it stimulates the patient or the patient's mother to wash out the eye thoroughly in order to remove all traces of it. Thorough irrigation of the eye is important. He uses a flat-pointed cautery to scorch the ulcer without touching it. To counteract photophobia in children he bandages the good eye, and in phlyctenular keratitis uses dionine in pure powder.

Mr. STACK stated that one group of ulcers gets well in 24 hours after the commencement of atropine treatment; another group, generally with a constitutional basis, is not affected.

Mr. POLLOCK also scorches the ulcer, and thinks paracentesis preferable to the Saemisch section. He lays stress on the importance of keeping down tension; he clears out the teeth of adults if necessary, and stops sweets in children.

Mr. H. P. BENNETT (Newcastle-on-Tyne) never ties up the eye, and uses hot bathing for 20 minutes every two hours and even at night, if necessary. If the

Ophthalmia Neonatorum.

In opening a discussion on the Causes and Prevention of Blindness at the Ophthalmological Section of the Newcastle meeting, Mr. N. Bishop Harman made some trenchant remarks on the prevalence of ophthalmia neonatorum. We entirely agree with him that more might be done to prevent damage to sight from this cause in spite of the optimism of the Ministry of Health, as shown in a recently issued report of the Principal Medical Officer:—

> "The good results reported, the large proportion of total cures (due in part to the number of slight or doubtful cases notified), the almost complete absence of total blindness, and the relatively few cases of damaged vision, speak well for the care with which the disease is treated and nursed."

The reference is to the reports of health officers for the year 1919, but the reports for 1920 tell a different story. Fortunately, if we may say so, the blinded infants in many cases do not survive. Even should local authorities be too optimistic, there is an army of child welfare workers in the field to remind them of the real position. And it may be added that the Second English-Speaking Conference on Child Welfare, held in London in July, unanimously passed a resolution drawing the attention of the Ministry of Health to the inadequate methods of prevention and treatment at present prevailing.

There are only three possible lines of defence: (1) treatment of the vaginal disease of the mother; (2) treatment of the eyes of the infant at birth; (3) early skilled treatment of the disease. Mr. Harman dealt with the first and the third of these, saying: "Prevention of the disease can be secured by the treatment of the vaginal disease of the expectant mother: this is the one and only certain means of prevention and it is within our power to accomplish this desirable end." It is no easy matter, however, to get hold of the expectant mothers for treatment; it may become easier as the work of antenatal clinics grows. Most ophthalmic surgeons pin their faith to the treatment of the infant's eyes at birth with a colloidal silver solution. At the Conference already referred to, Dr. Janet Campbell, senior medical officer for child welfare of the Ministry, gave figures for 50 unselected maternity homes which showed 74 cases of ophthalmia among about 9000 births, a highly unsatisfactory percentage. American representatives stated that systematic treatment of the infant's eyes had, practically speaking, abolished ophthalmia in certain districts of the United States, and it would be well that the procedure adopted should be made known in plain language and promptly. Mr. Harman's remarks on the third line of defence deserve special attention. "What is now needed," he said, "is the establishment of such medical arrangements that diagnosis and treatment can be made as swiftly as the fire-brigade can be brought in when there is an outbreak of fire in our homes." He would like to see established in the centre of every convenient area an ophthalmia unit. Prompt removal to hospital of mother and child is already a fact in Liverpool, while in London the benefits of hospital treatment are almost nullified by tardiness of removal.

This question of delay is crucial. Medical officers of health and ophthalmic surgeons know full well that there is frequent failure to secure skilled treatment at once. The case often reaches the ophthalmic surgeon after a spell of inefficient treatment during which irreparable damage to the eye has been done. The birth attendant may see so little of these cases as not to notice the danger signal or to recognise the need for a "fire-brigade." To some extent the medical schools and hospitals are at fault. The Ophthalmological Section at Newcastle passed a resolution in favour of the appointment of ophthalmic surgeons to all lying-in hospitals. If this suggestion be acted upon a great step forward will have been taken in the education of medical students and midwives on the serious nature of this disease; the means to be adopted for its prevention and the need for its prompt treatment in the event of a breakdown of the first two lines of defence will become apparent.

◆

The Combined Treatment of Malignant Disease.

The Council of the British Association for the Advancement of Radiology and Physiotherapy, of which Dr. Robert Knox is president, Dr. Alastair MacGregor and Dr. F. Hernaman-Johnson joint hon. secretaries, has taken up the reconsideration of the situation in regard to the treatment of internal cancer, suggested by a leading article in The Lancet of July 2nd. Earlier in the year we drew attention to the remarkable work on deep X ray treatment of uterine carcinoma at the Frauenklinik in Erlangen, work which for one reason or another had not attracted in this country the attention which it merited. Admittedly no new principle was involved, but Prof. L. Seitz and Prof. H. Wintz had been successful in applying to the diseased uterus quantities of X rays of a higher degree of penetration than those hitherto employed and in devising a careful system of measuring the dosage. The Council of the B.A.A.R.P. is in full agreement with us that this constitutes a real contribution to progress on the part of the Erlangen school.

But whilst thus agreeing with our statement of the merits of the Erlangen technique, the Association takes us to task for what it regards as an ill-advised pronouncement and disagrees with emphasis with the conclusions there expressed. "The time has *not* yet come," so runs the statement issued to the lay press, "when radiotherapy may be regarded as the first choice in the treatment of the majority of cases of cancer." We never said that it had, as any careful reader of the article in question may see for himself. Assuming the claims for the irradiation of malignant cases to be substantiated, the advantages to be gained will be readily appreciated. Cases would come under observation at an earlier stage. These were the actual words we used, and the statistics relating to the treatment of cancer by excision, whether or not supplemented by radiation, are not so rosy as to exclude the need for carefully exploring other paths. In a survey of these statistics given in the current number of *Medical Science*, over the initials of Mr. W. G. Spencer and Dr. C. Lillingston, it is stated that excision in cancer of the breast fails to cure in more than half the cases, while the plea that failure is attributable to the excision being done too late is suggested to be untenable in many cases. Statistical evidence in regard to the value of radiation is singularly wanting. Writing in 1919, Mr. Sampson Handley admitted that for the 14 preceding years every case of breast cancer upon which he had operated had received a prophylactic course of X rays, and he presumed that the rays were calculated to arrest the permeation of the disease through lymphatic

Affective thinking is incoherent and uncritical and often loses its end; its defects can be noted in some orators, and, the author might have added, in those psychasthenics—typified by Mrs. Nickleby—who lose conscious control of the verbal stream. In directed thinking we may commit mistakes, but they are criticised and corrected with a conscious aim in view. Distraction results when the fore-conscious wish is censored; but if the fore-conscious wish and the conscious aim are in agreement then affective and directed thinking are united for the fulfilment of the wish. We become aware of the end-result, but not of the preceding chain, and this end-result we call intuition or inspiration. Memory can be considered apart from awareness, and this allows the author to attribute memory to creatures near the bottom of the animal scale; there the affect rules, but in man the intellectual aspect has been so developed that we are able to act and think voluntarily by control of the affect. The primitive process, however, still goes on within us, and is manifested through absent-mindedness and distraction, in errors and mistakes of our daily life, as well as in hysteria and neuroses; inspiration borrows its mechanisms and it explains our behaviour whenever emotions prove stronger than our will.

It is difficult to estimate the amount of originality in this work; some of the material is a presentation of old facts under a new aspect, and some consists of re-statements of old observations. Dr. Varendonck, in assuming that "perception" has hitherto been used only in terms of consciousness, seems unaware that psycho-analysts have for long regarded the fore-conscious as having the power to perceive and retain on its own account. In a modest introduction the author says that he addresses himself to English readers because they, of all nations, show the greatest interest in psycho-analysis. He forgoes any literary claims, but he may be congratulated on his mastery of idiom and meaning; his sentences, however, are often awkward and involved, and a free excision of redundant phrases would help the reader. Other criticisms might be made, but the book is a record of spade-work carried out with honesty and insight, and should rank as an important contribution to psycho-analytical literature.

HUMAN PHYSIOLOGY.

By Prof. LUIGI LUCIANI, Director of the Physiological Institute of the Royal University of Rome. With a Preface by Prof. J. N. LANGLEY, F.R.S. Edited by M. S. PEMBREY, M.A., M.D., Professor of Physiology, University of London. Vol. V. London: Macmillan and Co., Ltd. Pp. 422. 30*s*.

THIS is the last and concluding volume of Luciani's *magnum opus* "Fisilogia dell' Uomo," the first volume of which in English garb appeared in 1911. The first volume of the second Italian edition was published in 1904. This volume deals with metabolism, temperature, reproduction, and so forth. Prof. Luciani also enters the no-man's land between physiology, psychology, and philosophy in the stages of life and death, dealing with maturity, virility, senility, the critical age, personality in the aged, and the author's theory of death. He distinguishes between the *primum moriens* and the *ultimum moriens*—the latter phrase aptly used by Oliver Wendell Holmes in referring to the decayed and decaying tall hat, when tall hats were the fashion, as the "*ultimum moriens* of human respectability." The last chapter of nearly 70 pages on "the human races" is really an appendix, written by Luciani's assistant, Prof. S. Baglioni, and deals with ethnology and anthropology in relation to physiology. In the chapter on "Exchange of Material," besides giving much more than the usual information, Prof. Luciani adds an account of "authenticated fasts."[1] Of vitamins in the Italian text there is no mention, but the British editor adds a note referring the reader to the special report (No. 38) on this subject issued by the Medical Research Council in 1919.

Prof. Luciani discusses in some detail the thermic economy of the organism and human nutrition. The generative system of the female, pregnancy, parturition, and puerperium, are dealt with at length on familiar lines, but in the section dealing with male organs no account is given of any work done since 1910, when F. H. A. Marshall's "The Physiology of Reproduction" was published. The observation on the condition of the epiphyseal cartilages in a castrated man as shown by the X rays ascribed to Lannois and Roy should read Launois and Roy, and the term "nucleus of Blecard" is unfamiliar to us. In dealing with old age, while mentioning Aristotle, Cicero, Camerario, Bacon, Charcot and several others, the work of Humphry of Cambridge seems to have escaped the author's wide outlook.

Throughout the work is written in the fascinating style of which Luciani was a master, and is illuminated by copious references to general literature. We are indebted to the editor, translator, and publisher for the opportunity of studying human physiology as expounded by one of its most eloquent and successful advocates, even though we had to wait a decade between the issue of the first and last volume.

REGIONAL ANATOMY.

By T. B. JOHNSTON, M.B., Ch.B. Students' Synopsis Series. London: J. and A. Churchill. 1921. Pp. 438. 12*s*. 6*d*.

Prof. Johnston has provided, in this little book, an excellent member of this well-known series of students' manuals. It is intended for use with the dissected parts, the object being to refresh the reader's memory rather than to fill him up with a mass of "examination" detail. Thus the volume cannot justly be described as a "cram-book." The descriptions are clear and good, if short in some cases. Prof. Johnston points out that he is writing for the average student, who will become the average practitioner, and therefore leaves out unnecessary details. We might disagree with him as to which details were unnecessary, but few would dispute the wisdom of including in this class the fissures of the cerebellum; we are therefore glad to see that, in the short and clear account of the central nervous system, no more space than is absolutely necessary is taken up by this at present sterile subject.

DISEASES OF THE LUNGS.

Lehrbuch der Lungenkrankheiten. Second edition. By ADOLF BACMEISTER, *Professor of Medicine at the University of Freiburg i.B., Superintendent of St. Blasien Sanatorium in the Black Forest.* Leipzig: George Thieme. 1921. With 103 illustrations and 3 coloured plates. Pp. 339.

Prof. Bacmeister's book on diseases of the lungs begins with an account of the anatomy and physiology of the chest, and the various methods for its examination. A single chapter is devoted to tracheitis, bronchitis, and broncho-pneumonia, and another to chronic bronchitis, bronchiectasis, and emphysema. Pulmonary tuberculosis is allotted three long chapters, and such important diseases as asthma and pneumonia are given the ample space they deserve. The author has arranged his material in so orderly a fashion that in spite of the size of his book it is easy to find any particular information that may be required. Thus the reader interested in little but the therapeutic aspects of disease will find all the information on this score tidily appended to each chapter.

Rightly or wrongly, German works of science labour under a reputation for turgidity and redundance. Prof. Bacmeister's book is a pleasure to read, not only on account of its intrinsic merits, but also because of his crisp and incisive language. Not a word is wasted, and yet sentence follows sentence with an easy fluency seldom found united with parsimony of words.

Annotations.

"Ne quid nimis."

THE OPIUM TRAFFIC AND THE LEAGUE OF NATIONS.

IN THE LANCET of April 30th reference was made to the position in which the effectuation of the Opium Convention of 1912 then stood, both in regard to our own national undertaking in the matter of legislation and also, what is not less essential, the international aspect of the question. The regulations made by the Home Office under the Dangerous Drugs Act, 1920, as now revised, came into force on Sept. 1st. The report of the Advisory Committee of the League of Nations which met in May has been approved by the Council of that body, and will be laid before the Assembly which meets at Geneva this month. The official *Monthly Summary of the League of Nations*, issued from Geneva on June 1st, purported to give an account of the work so far accomplished towards putting the Opium Convention into force. It is there naively remarked: "Thus it seemed to the Committee that the Hague Convention had not been put into practice everywhere, and that, moreover, its recent application did not permit serious conclusions to be drawn as to its efficacy. While certain Governments had enacted rigorous measures of control, others had not yet adopted the Hague Convention." A questionnaire has been circulated to all the Powers with a view to ascertain what really has been done towards restricting the use and stopping the abuse of opium, morphia, cocaine, and other dangerous drugs. The replies, when received, will probably show that the statement that the Convention "had not been put into practice everywhere" might more correctly have been rendered, "the Convention has not been effectively put in force anywhere." We read of increase of acreage under poppy cultivation in recent years in China and India; of tons of British-made morphia being exported to the Far East; of the wholesale smuggling of morphia from Japan into China, as well as the manufacture of large quantities of morphia in Japan from Indian, Korean, and Japanese opium.

In THE LANCET of May 29th, 1920, we urged the need for "control at the source of the fabrication of these drugs," and pointed out that "over-production must inevitably lead to illicit consumption with its attendant social and moral degradation." We are accordingly glad to learn from the *Monthly Summary* for July that the Council has taken a step in advance of the Advisory Committee's report towards reducing production of these drugs to what is required for "strictly medicinal and scientific purposes," and to this end has invited the Committee to determine what amounts of opium, &c., are required for these legitimate uses. We further note in the August *Monthly Summary* that the delegate of India on the Advisory Committee seems to interpret the Convention as placing no restrictions on raw and "prepared" opium like those placed upon traffic in morphia, &c. He admits that the eventual "suppression" of the fabrication of and traffic in opium "prepared" for smoking was contemplated by the Convention, and that "medicinal opium" is to be restricted to "medical and legitimate purposes." The same restriction is apparently to apply to all preparations of opium containing more than 0·2 per cent. of morphia. It is not clear, therefore, whether the contention really is that, notwithstanding these restrictions on the derivatives of opium, no restriction is to be applied to the cultivation of the poppy in India or the raising from it of "raw opium."

On Nov. 25th, 1920, it was stated in the House of Commons that "exports of opium, morphia, and cocaine, and their preparations" to certain countries were only licensed "on production of a certificate signed on behalf of the Government concerned that the consignment is required exclusively for legitimate scientific or medical purposes," and that the extension of similar procedure to other countries was being negotiated. It will be interesting to know how far this system is now in effective operation, whether it applies to exports of opium from India, and what results have been achieved as indicated by the figures of exports and imports of these dangerous drugs compiled by the Board of Trade. Meanwhile it is satisfactory to learn that under the Postal Union Convention, recently signed at Madrid, it is prohibited to send by letter mails any of the narcotic drugs in question; and the parties to the Convention have bound themselves to propose to their respective legislatures to enact measures to inflict punishments for infringement of this regulation.

FIXATION OF COMPLEMENT IN TUBERCULOSIS.

A HANDY test for active tubercle would be a great boon to medicine and it is largely for this reason that, of the many interesting questions which centre around fixation of complement in tuberculosis, those which relate to its behaviour in diseases other than tuberculosis are the most practical. Before the war Besredka and Inman showed that with the antigen prepared by the former cross-fixation with syphilitic serums was liable to occur. Subsequent researches have now enlarged the issue and two separate questions are, in reality, involved: (1) Will the serums of patients suffering from diseases other than tuberculosis give positive reactions, and if so, what diseases? (2) Will other antigens give a positive reaction with tuberculous serums, and if so, what antigens? These questions have arisen in the past with regard to the Wassermann reaction and, inasmuch as bacterial infections are commoner in this country than are protozoal, they may be more difficult to answer in tubercle than in syphilis. Fixation in diseases other than tuberculosis has engaged particular attention in America, where large series of cases have been dealt with; and now the second question, that of the non-tuberculous antigen, is being raised. Urbain and Fried,[1] working in Besredka's laboratory, took known tuberculous serums and tested them against various bacillary antigens, including streptococcus, staphylococcus, pneumococcus, *B. anthracis*, *B. subtilis*, *B. diphtheriæ*, and members of the enterica group. One serum, that of an immunised horse giving a positive reaction with Besredka's antigen, gave uniformly negative results with these various bacillary antigens, whilst the serums from 20 tuberculous patients gave positive results in three instances with the antigen of *B. diphtheriæ* and in two instances with that of *B. subtilis*. In the next group Urbain and Fried used Besredka's tuberculous antigen and antiserums of horses immunised against various bacterial diseases, such as plague, tetanus, anthrax, and diphtheria. Antidiphtheritic serum was the only one which gave a positive result. In the third group Besredka's antigen was tested against human serums from patients suffering from various bacterial (enteric, erysipelas, osteomyelitis, diphtheria, &c.) and non-bacterial diseases (carcinoma, sarcoma, mental diseases, &c.). Significantly enough, the only serums to give positives in this third group were those of four cases of diphtheria, all of whom had recently had antidiphtheritic serum administered. In all instances, however, the positive results obtained do not appear to have been so strongly positive as the true fixation result with a tuberculous antigen and tuberculous antibody.

We print in our present issue a further report to the Medical Research Council by Dr. A. Lisle Punch, in which he records the results of complement-fixation tests made with the special technique described by him in THE LANCET last year (1920, ii., 647).

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 3, 1921.

Industrial Medicine.

During the last 150 years universal changes in our mode of living have been the direct outcome of inventions and of their application in industries. Meanwhile, the environment of those industrially employed has undergone modification; and the study of how the human frame reacts to these changes of environment has arrived. This study, which constitutes industrial medicine, is entrancing, because industry frequently presents an unintended human experiment upon a large scale which can be seen and observed. Contrasts abound: from the hot humid atmosphere of tin-mines to the dry cold of food-storage chambers; from radiant heat emanating from molten metal, with its tendency to cause posterior cortical cataract, to the intense darkness of coal-mines with its attendant nystagmus; from the overcrowded workshop of the tailor, who experiences an excess of phthisis, to the open-air life of the farm labourer; from exaggerated atmospheric pressures, with risk of caisson disease if decompression is too rapid, to diminished atmospheric pressures in aviation, with cardiac, respiratory, and mental disturbances. Here the hearing of a boiler-maker is impaired; there, as in writer's cramp, neuro-muscular coördination has broken down; or some mason working in sandstone succumbs to tuberculous silicosis, while his fellow-worker in limestone escapes unaffected. Or maybe it is the skin which fails to withstand the action of fat solvents or of dehydrating substances; or the liver which undergoes atrophy under the influence of tetrachlorethane or trinitrotoluene. Ramazzini, the Paduan, were he still alive, would revel in the opportunities modern occupations present of investigating the occurrence and elucidating the causation of disease. Sir Arbuthnot Lane, discussing recently the influence exerted by our surroundings, maintained that the bony system of some labourers, in response to the needs of their occupations, differs more from the normal than does the normal from the skeleton of the higher ape. If physical strain can in this way modify the skeleton, exposure to the widely varying conditions enumerated above must assuredly modify the function of the more easily influenced organs of the body.

Considerations such as these more than justify the existence of a special section of the British Medical Association devoted to Industrial Hygiene. This section does not come together annually, but seized the opportunity of holding a meeting when the Association was gathered together in the industrial centre of Newcastle, and we report the consequent proceedings at length in our present issue. The President, Sir Thomas Oliver, whose activities in the field of occupational diseases have earned world-wide recognition, reviewed a century of legislation aimed at ameliorating the health of workers. He pointed to the wholesale reduction in lead poisoning and to the abolition of phosphorus necrosis. He called for further research into such subjects as industrial fatigue and its relation to ill-health, and into the chronic effects of carbon monoxide upon which he has himself already embarked. He stressed the need for the general practitioner to acquaint himself with industrial hygiene on account of his duties in connexion with compensation cases and to enable him to advise his patients and also their employers as to the effect of occupation upon the health of the worker. A notable point in the proceedings was the unanimity expressed and reiterated by Sir T. Oliver, Capt. W. E. Elliot, M.P., Prof. E. L. Collis, and Sir Kenneth Goadby in their papers, and by those who took part in the discussions, on the need for industrial convalescence. All agreed that the work carried out by the Ministry of Pensions on behalf of those incapacitated in the field of war should be continued for those disabled in the field of industry. Prof. Collis estimated that at any time there must be 58,000 limbless civilians needing occupational re-education; while a far larger number, still possessing some earning capacity, are precluded from full-time employment on account of different forms of ill-health and disability. These workers are for the most part ready to work so far as in them lies, and would willingly escape from the industrial scrap-heap to which they are relegated; they feel the ignominy of being a burden upon others and often upon the rates.

Prof. Collis presented, in the form of debit and credit, the value of medical services to industry. His argument is conclusive; but we suspect that he presents the case in this way rather to attract attention than with implicit reliance upon "the few short sums in arithmetic" which are given. The point is clear that employers of labour must not look upon their contributions to national health insurance as other than an expensive effort at patching up those who have broken down in health, and in no way as relieving them from the more directly paying proposition of maintaining in health and efficiency those upon whose productivity they rely. Sir Kenneth Goadby carried the discussion into one particular realm of industrial medicine, which is at present provoking considerable controversy—viz., the question as to whether the continued use of lead compounds in paints should be prohibited. Apart from its controversial aspect, his contribution is of value in disclosing the important part played by the volatile constituents of paints in causing ill-health among painters. The argument is probably sound that, if some non-poisonous material were substituted for lead compounds as the body of paints, this form of ill-health would persist; but Sir Kenneth Goadby does not consider the possibility of small doses of lead accentuating the action of these volatile constituents. There is a further point; if white lead were no longer used in paints, the manufacture of white lead itself would almost cease with its attendant dangers, and there would be some reduction in the amount of lead smelted. The consequent reduction in risk of plumbism in these industries, quite apart from the effect upon painters, is a matter of moment. Occupational hygiene will be benefited by the reliance of industrial managers upon expert statistical and medical advice. Few can doubt that health and contentment are closely correlated and that labour unrest is but the psychological expression of abnormal physiological functions. When once captains of industry perceive that the medical profession holds the key to labour unrest a demand for its services must arise which there are far too few trained to-day to meet.

in. At the height of the disease the Eustachian tubes were impermeable even on vigorous inflation. It was a remarkable fact that none of the patients had recently suffered from a cold in the head or a sore throat. Examination in some cases showed a slight chronic rhinitis, but no signs of acute inflammation or much swelling of the mucous membrane. On the other hand, purulent catarrh, with or without swelling of the adenoid tissue in the nasopharynx, as well as redness and swelling of the opening of the Eustachian tube, were frequently observed. Dr. Amersbach seems to have been discouraged from making any bacteriological examination by the fact that investigations of the kind undertaken by ophthalmologists on swimming-bath conjunctivitis had been inconclusive. He suggests that the involvement of the Eustachian tubes in swimming-bath tubal catarrh may occur in one of two ways—namely, either by infected lacrymal secretion reaching the tubes as the result of blowing the nose or swallowing, or directly by infection of the pharynx by the bath water. The affection is most frequent in young persons, but older individuals are not immune, as three of the cases were over 36 years of age. Treatment consisted in the application of the usual methods for dealing with catarrh of the Eustachian tubes.

THE VISCERAL SENSORY NERVOUS SYSTEM.

MORE attention has been given by investigators to the efferent nerve paths through which impulses reach the viscera from the central nervous system than to the afferent sensory paths from viscera, and to the consequent remarkable reflex effects that one viscus may exert on one or more of the other visceral organs. A recent systematic study[1] from the University of Chicago fills in this gap to some extent. In it A. J. Carlson and A. B. Luckhardt record a series of observations on several classes of vertebrates, beginning with amphibians and reptiles. Starting from the fact that in man strong contractions of the empty stomach can produce reflex effects on the cardiac and vasomotor centres, the authors propose to determine the effects which the afferent visceral system exerts on the skeletal muscles, the respiratory, intestinal, and urinary systems, and on the heart and blood-vessels. In frogs, *Rana pipiens* and *catesbiana*, tonus is well marked, and under certain circumstances rhythmical contractions may occur, and even the entire lung be emptied of its air. Section of the sympathetic nerve alone has no effect on the lung tonus, but section of the vagus caused sustained hypertonus of the corresponding lung, and on electrical stimulation of the peripheral end of the vagus the tonus is inhibited and the lung returns temporarily to the normal condition, the rhythmical contractions disappearing. The authors conclude that in the frog the inhibitory fibres in the pulmonary branches of the vagi are in continuous or tonic activity, and thus limit the peripheral motor lung automatism; for, if these influences are cut off, the lung falls into a state of sustained or continued tetanus or hypertonus. Stimuli of all kinds influence this pulmonary mechanism; reflex contraction of the lung can be brought about by stimulation of the skin of the upper jaw, slight mechanical stimulation of the anterior nares, the urinary bladder and cloaca, by electrical stimulation of the urinary bladder, mesentery, œsophagus, pyloric end of the stomach (but not the fundus end), and duodenum, and of the central end of the brachial nerve; indeed, stimulation of almost every sensory nerve is followed by contraction of the lungs. After section of the vagi nicotine causes the lung tonus to disappear for a moment owing to primary stimulation of the inhibitory mechanism. Large doses of nicotine, however, cause contraction, probably due to direct muscular stimulation. Atropin even in large doses scarcely, if at all, paralyses the inhibitory fibres, adrenalin at once arrests the rapid rhythmical contractions and the increased tonus.

The lung automatism and reflexes were then studied in the salamanders—Necturus and Axolotl. These, besides larger gills—their chief respiratory organs—possess two long muscular sacs or "lungs" which communicate by means of a small aperture with the pharynx. The results obtained correspond closely to those obtained with the frog. It is known that the lungs of reptiles respond to direct stimulation and that the lung musculature is under the influence of the vagus; indeed, one vagus may, in some species, influence both lungs, and rhythmical contractions of the lung have been observed as long as the vagi and bulb were intact, while in turtles the isolated lung may exhibit rhythmical activity. The authors investigated two varieties of turtles and one species of snake. Section of the vagus at once abolishes the normal contractions of the lung on the same side, but those on the opposite lung only temporarily, due to the fact that the connexion with the bulb on that side is still maintained. Strong stimulation of the peripheral end of the vagus in turtles causes contraction or even complete tetanus. The lung-vagus contains both motor and inhibitory fibres, so that stimuli affecting the lung may cause one or other effect. Stimulation of peripheral sensory nerves of the skin, intestinal canal, and urogenital system always causes increase, never inhibition, of the contractions of the lung, while the skeletal musculature involved in the respiratory act is often inhibited by the same stimuli. Much the same results were obtained in the snake investigated—*Eutenia elegans.*

Taken broadly, the influence of the central nervous system on the reptilian lung is chiefly motor, in the frog chiefly inhibitory, but also motor, whilst in the salamander it is exclusively inhibitory. In frogs and salamanders there is such a well-developed automatism of the lung that when the central inhibition is suppressed (vagotomy or destruction of the bulb) the lungs pass into a tetanic condition, while in reptiles lung automatism primarily depends on the motor impulses passing in the vagus, so that after decerebration or vagotomy the lungs are flaccid and quiet. The methods used are fully described in the text, and we look forward with interest to the results obtained in other classes of vertebrates.

FAMINE IN RUSSIA: AN INTERNATIONAL CONFERENCE.

Mr. Lloyd George described the famine in Russia as the most terrible visitation that had afflicted Europe for centuries. At the conference called by the joint council of the International Red Cross and the League of Red Cross Societies, which met in Geneva on August 15th and 16th, twenty governments and Red Cross societies were represented, in addition to several international bodies, leading relief agencies, such as the League of Nations, the International Labour Bureau, the Friends' War Victims and Relief Committee, the Imperial War Relief Fund, the Save the Children Fund, and the Parliamentary Relief Committee. The chair was taken by Mr. Gustave Ador, who was supported by Sir Claude Hill, the acting-director of the League of Red Cross Societies. The most interesting speeches came from the delegates representing the famine stricken countries. Mr. Chavichvily, the delegate of the Georgian Red Cross, painted a lurid picture of the sufferings of his country since the Bolshevist invasion. A population of over three millions is practically without food, people are dying in the street, and there cannot be found the means to bury all the dead. Suicide and epidemic disease swell the total of these. Among the first victims of cholera must be counted the Catholicos, the head of the Georgian Church. Dr. Bagotzky, the representative of the Soviet Red Cross at Berne, was present on the second day and transmitted a report through Mr. Paul Birukoff, at one time secretary of Leo Tolstoy and his official biographer, who represented at the conference the Pan-Russian spaces in areas immediately outside that of the excision, but up to the present time no statistical publication of results obtained in this country and extending over years is available. F. BLUMENTHAL's analysis of results at the Charité in Berlin did not show in 1919 an advance in the success of radiation over that obtained in 1915, and on the whole are not appreciably better than some series of results attained by excision alone. At the Surgical Section of the annual session of the American Medical Association held at Boston last June it was agreed that only 25 to 50 per cent. of patients survive excision of the breast for cancer more than three to five years.

---

[1] American Journal of Physiology, vols. liv. and lv., 1920–21.

Hasty opinions on medical matters should certainly never be given wide publicity, and cancer, unfortunately, is a field in which public disappointment at unfulfilled promises may readily bring discredit on promising fields of treatment. But it is no good closing our eyes to the fact of a relative want of success in our surgical methods of dealing with a disease of increasing dimensions. A week or two ago we called attention to the picture drawn from the *Bulletin* of the League of Red Cross Societies of cancer as it really is. Radium may do something sometimes, morphia may help a little at the end, but knowledge, if it is given to the people in time, can save these lives and all this suffering. Our aim in publishing these articles was twofold: first to insist on the sufferer from cancer coming under medical observation at the earliest possible stage in the malady; and secondly, to ensure a thorough exploration of all the resources of medicine in dealing with the disease. Between the surgeon and the radiologist coöperation should be of the most intimate kind. Obviously the slightest antagonism would disadvantage medicine as well as the patient. Advancement of radiology, as the Association has clearly seen, is part and parcel of advance in medicine as a whole.

◆

The Census of 1921.

THE preliminary report on the census taken last June has been issued with commendable promptitude, and although only the simplest elements are yet available—enumerations by sex and area without distinction of age or civil state—the figures require some comment. The population of England and Wales enumerated in June, 1921, exceeds that of April, 1911, by 1,814,750 persons, corresponding to a decennial rate of increase of 4·93 per cent., the lowest rate yet recorded, less than half that of the previous decennium and not a third of the maximum increase which took place between 1811 and 1821. This rate of increase is, however, far greater than that of France, whose population, including that of Alsace and Lorraine, has diminished 5·5 per cent., and greater than that of Switzerland (an addition of 3·4 per cent.) but less than that of Sweden (an addition of 8·7 per cent., and a greater rate than in the previous decennium). The figures for three of our daughter States, the Australian Commonwealth, New Zealand, and the Union of South Africa, are available, and each shows a percentage increase of some five times the mother country's rate (Australia 21·8, New Zealand 20·8, Union of South Africa 19·2—in each case aborigines are excluded).

The war has, of course, been mainly responsible for the great slackening in the rate of increase, although, apart from the war, the declining birth-rate would have had an effect. The excess of births over deaths fell from just over 4 millions to just over 3 millions, and this is more due to a decline of births than to an increase of deaths; the former diminished by 1,015,233, the latter increased by only 21,135. The direct losses of the war fall, for the most part, under another heading, which, with perfect accuracy but to the lay reader with a grim humour, runs: "Loss representing balance of outward over inward passenger movement," and amounts to 1,193,750. We know whither the great majority of those outward moving passengers journeyed. The distribution of the population does not differ in broad categories from that of ten years since. In 1911 78·1 per cent. were enumerated in urban and 21·9 per cent. in rural districts; in 1921 the figures are 79·3 and 20·7. The report says that "the present rural district population is slightly less numerically than the similar 1911 population. The increase within the existing rural areas, however, is not seriously below the mean for the whole country, and indicates that the actual diminution is due merely to the normal growth of urban centres and not to any serious migration from country to town, such as that which took place during the latter half of the last century and which is reflected in the intercensal changes shown for the decennia between 1881 and 1901." This statement may ultimately need qualification if we give to the word "country" a less technical meaning. For instance, in the Administrative County of Essex the rural districts which return an increase of population are, with the possible exception of Billericay, either within the spheres of influence of industrial centres or, like Epping, outer suburbs of London. The strictly agricultural districts, such as Belchamp and Bumpstead, have declined.

The enumerated population of the Administrative County of London is less by 38,436 persons than in 1911, but Greater London has increased by 3·1 per cent. and now includes 7,476,168 persons. Amongst the great towns with smaller populations than in 1911 are, rather surprisingly, six manufacturing cities in Lancashire, Blackburn, Bury, Burnley, Oldham, Bolton and Rochdale; the reporters find it difficult not to associate these decreases with the prodigious increases found in Blackpool (64 per cent.) and neighbouring holiday resorts. A result of the war is an acceleration of the change in ratio of females to males, which was 1055 in 1881, 1064 in 1891, 1068 in both 1901 and 1911, 1095 in 1921. Sussex and Surrey return the highest (1273 and 1187), and Glamorgan and Monmouth the lowest (964 and 939) proportions of females. These are, perhaps, the most striking of the preliminary results. It would be idle to speculate upon the hygienic consequences of what has occurred in the absence of details which the subsequent reports will reveal. In particular, we refrain from either pessimistic or optimistic comments upon the increase. Much of the copious "literature" upon "race suicide" and "birth control" has no scientific value.

CANCER RATES IN EDINBURGH AND MANCHESTER.—The medical officer of health of Edinburgh, dealing with the city death-rates from cancer for every year since 1898, has shown that an incidence of 0·88 per 1000 of population for that year rose to 1·10 per 1000 in 1908, to 1·35 per 1000 in 1918, and to 1·39 per 1000 in 1920. Edinburgh is not peculiar in this respect. In an industrial district like Manchester 4 per cent. is almost exactly the annual rate of increase. In the country cancer is much more rare. The proportion of men to women sufferers is now 1 to 1·3, and in Manchester at present is 405 men to 403 women. Between 1899 and 1919 the death-rate in Manchester increased by 91 per cent., but there are certain factors which somewhat mitigate the disproportion.

boys. Cooks, bakers, stewards, and the barber had a daily bath by order. Such ratings as these got a short spell of physical drill daily. Dentists (contract) were coming in; the province Schleswig subscribed a fund which enabled a dentist to be hired to deal with the teeth of men in the *Schleswig*. This was very practical charity, and the principle might well be followed in this country. Suppose the city of Dublin annually sent money to the captain of H.M.S. *Dublin* to buy papers for the men and to help, for example, a man who had lost teeth, by an accident not attributable to the service, to get a new set. At Tsingtau crews of ships under refit were lodged in barracks ashore, an improvement often asked for on this side of the North Sea, and carried out at Bombay and Trincomalee. Latrine paper was served out for the use of diarrhœa cases which were, or might be, infectious, and a bucket of cresol solution was put near their closet for hand disinfection. *Scharnhorst* in hot weather gave her men two baths a day, and her stokers at Tsingtau got eight days' special leave by watches in a barracks up country for the good of their health. Bugs and cockroaches were being energetically pursued.

1913-14: Newspaper reading and smoking in the water closets made it necessary that the seats should be altered and made less comfortable. Some of the men paid to have their teeth put right and bought tooth powder from the canteen. A formalin disinfector was fitted in all flagships. Hand washing after work and before meals and cleaning of teeth were officially pressed on the men. Atropin was found useful for sea-sickness. Men's blankets were enclosed in washable covers to keep them clean. Amongst the drinks provided to win the men away from beer *Loreley* issued yoghourt, Bulgarian bacillus milk. This should have prevented indigestion; it was introduced by the medical officer—it is a pity the result is not stated.

RAT DESTRUCTION AND PLAGUE IN INDIA.

The epidemics of plague in India, for all practical purposes, may be said to be entirely dependent on epizoötic plague in rats. Measures for the eradication of this malady have therefore to be directed mainly to reduction of the rat population, either indirectly, by limiting their shelter and food and by fostering their natural enemies, or directly, by destruction of these rodents by means of traps, poison-baits, and the like. To produce the greatest results the methods of rat destruction should be applied in the plague "off-season," that is, in the interval between the decline of one outbreak and the commencement of another. The measures are particularly urgent in villages and in quarters of towns where there is reason to believe that epizoötic plague will persist during the off-season. For some years Major J. C. G. Kunhardt, I.M.S., and Assistant-Surgeon G. D. Chitre have been engaged in carrying out work of an experimental kind on the rat question in Poona and adjacent districts. Of late they have devoted attention particularly to effecting improvements in the methods employed for destroying rats and changes in the composition of poison-baits and their relative values. The results of these experiments, so far as they have gone, have been recently published in the *Indian Journal of Medical Research* (Vol. VIII., No. 3). It was demonstrated by these experts that rat-traps varied in efficiency, but by a judicious selection of material for baiting the traps their utility could be further increased. Experiments were carried out with various poisonous substances, including hydrocyanic acid gas. As regards the latter, it is pointed out that its use for fumigation purposes will not be found satisfactory until some method is discovered for rendering Indian houses more air-tight while they are being fumigated. Much time was occupied in experimenting with the various poisons, the material used for making up the baits, and with the different patent preparations advertised as efficient rat-killers, including "Rough on Rats," the "Common Sense Rat-Exterminator," the "Punjab Rat-Exterminator" (a phosphorus compound), and others. But after prolonged experiments it was demonstrated that the best rat-killer was barium carbonate, three grains of which will kill a rat of any size. In comparison with the 'Punjab' rat-exterminator it was found to be twice as poisonous, while it killed in a shorter time. The cost of the minimum lethal dose of the Punjab rat-exterminator is at least 60 times greater than the cost of the minimum lethal dose of barium carbonate. When this poison cannot be obtained the most suitable substitute is arsenious acid, if not otherwise contra-indicated. Like barium carbonate it appears to be tasteless. It is cheap and easily obtainable in India, but it has its drawbacks, and its use is not without certain dangers. Its lethal dose for an average-sized Poona *Mus rattus* is half a grain, but probably one grain would kill a rat of any size. The rat, being a sagacious as well as a suspicious animal, some ingenuity and care are needed in the preparation and laying of the poison-baits. By experiment the best material for making up poison-baits was found to be bajri (spiked millet) dough, this vehicle being six times more popular with rats than wheat, which formerly was commonly used for the purpose. The employment of sugar as an additional attraction to the bait, as was usually recommended, was found not only to be a useless extravagance but actually to diminish the amount of the bait consumed by about 50 per cent. Unfortunately these baits, made of three grains of barium carbonate and 12 grains of bajri dough, deteriorate rapidly and are practically useless on the second day. A dry mixture of barium carbonate and bajri flour, though less popular with the rats than the wet dough, does not deteriorate so rapidly. A rat when starving will probably eat anything from which nutriment may be extracted. In "go-downs," food stores, and such places rats are generally abundant and far from being underfed; to prevent the spread of plague by them it is urgent that these rats should be destroyed, and in such circumstances their powers of discrimination as to poison-baits require very careful consideration. It is believed that the use of the poison-bait described above will prove to be of higher efficiency in rat destruction than those formerly employed; and it is suggested that the real rate of efficiency in favour of the new bait may well be even greater in nature than it has been shown to be in the laboratory experiments. Finally, Major Kunhardt and Assistant-Surgeon Chitre express the opinion that the failure to eradicate plague in villages and towns at previous attempts was attributable to a large extent to the inadequacy of the measures employed for the destruction of rats.

THE PERIL OF THE AIR.

The airship disaster last week at Kingston-on-Hull has saddened two continents, and has drawn together the whole populations of America and England in a common bond of sympathy for the relatives of the 46 brave and distinguished men of the R 38 who perished by burning or drowning. Pioneers in a new enterprise are not prone to count their risk too exactly, or to set a price upon their lives, provided that the task is worthy of the risk. In this case no one except a few doctrinaires doubts the worthiness of the human aim to gain the mastery of the air by ships of light weight. Fragile and expensive they must needs be, but the onlooker is fain to ask whether the gas that supports the balloon need be capable of burning and exploding at all, and whether the oil that drives the machines need flash into flame at the slightest spark. Light petroleum has long been eliminated from ordinary household economy on account of its danger, and the heavier oils are already in use in certain forms of internal combustion engine. Of the group of inert gases discovered by Rayleigh and Ramsay, helium has an atomic weight of only 4, and the gas being monatomic is barely twice as heavy as hydrogen, and three times

Every laboratory worker will appreciate the difficulties encountered by Dr. Punch in devising a test containing five variables in such a way that the interpretation shall be unambiguous. Antigen, patient's serum with its varying anticomplementary power, guinea-pig's complement, hæmolytic serum, sheep's corpuscles—all of these possess complicated colloidal properties about which we, as yet, know little. Dr. Punch's present paper raises another group of questions—namely, the nature and right employment of controls. He records two separate groups of cases. In one series of 50 cases a colleague at Brompton made the clinical diagnosis, the author himself performing the laboratory test. In the other series of 185 cases the author again made the complement-fixation test, but the clinical investigator is not stated. The results in the two series are very different, and Dr. Punch himself offers no explanation of the divergence. If identical laboratory technique was used in both cases, presumably the explanation must be sought on the clinical side of the investigation. Should the same person make both the clinical and the laboratory tests he is faced with the possibility of subconscious bias in favour of one or of the other. Dr. Punch has eliminated what may briefly be called laboratory bias by asking Dr. A. Fleming to number the serums and retain the key to the numbering until the test was complete, so that he was unaware while estimating the complement fixation of the provenance of the serum. But he does not state what precautions were taken on the clinical side in this series of 185 cases, especially in regard to those in which the diagnosis of tubercle was considered doubtful. In a disease of such protean manifestations and ubiquitous distribution as pulmonary tuberculosis it is on the clinical side that difficulty in interpretation might be expected. The evolution of a test such as this is obviously expedited by placing both clinical and laboratory records in the hands of an assessor with a philosophic turn of mind.

DENTAL DECAY IN THE YOUNG.

IN another part of this issue we survey the main chapters in the report for 1920 of the School Medical Officer for the County of London. An important section in this report treats of dental decay in school children, a matter of urgent interest when we consider the far-reaching effects of this disease in after life. Dr. Hamer refers to the suggestion made by Dr. James Wheatley, of Shrewsbury, that the compulsory change in diet during the war—namely, the halving of the sugar ration, the partial elimination of sweets, the addition of offal to the flour, and the increased mastication of crusts and staler bread—produced a notable alteration in the condition of the teeth of the Shropshire school entrants, regretfully adding that the London figures lent no support to Dr. Wheatley's suggestion. Six months ago Dr. Wheatley himself, as the result of further investigation, admitted that the improvement fell far short of what his original figures indicated, although he still can trace some improvement, partly, he believes, resulting from the war conditions referred to, and partly owing to an educational campaign undertaken in the county.

Without trying to adjudicate whether or no Dr. Wheatley was over-sanguine, it is relevant to, discuss whether the plan of campaign conducted by Dr. Wheatley and Dr. Sim Wallace is on the right lines, and; if it is not, to formulate a better one. All of us, according to Dr. Hamer, hold dental decay to be a preventable disease, though there is no corresponding unanimity in respect of the methods to be used. We all recognise its evil effect on the physique of the nation, and the absurdity of establishing innumerable costly centres for treating, at the best, a fraction of the trouble. We are indeed almost forced into the position either of ceasing to talk about dental decay as preventable, or of formulating a complete campaign to prevent it. In an interesting paper read before the Central Counties Branch of the British Dental Association in June, 1920, Dr. Wheatley assumed general agreement on certain broad issues. His first two points were as follows: 1. That decay of teeth in its initial stages is caused by acid decomposition of carbohydrate food in contact with the teeth, and in no other way. 2. That vigorous exercise of the jaws is necessary for the proper development of the jaws, and consequently for the regular arrangement of the teeth. His fifth point was that there is reason to think that the development of the jaws and the enamel of the teeth is to some extent dependent upon the presence in the food of vitamin A, or something associated with it. Difference of opinion on the fifth point is not of vital importance, for babies ought to be breast-fed, and the breast-fed baby naturally gets its proper supply of vitamin and the vigorous sucking exercise necessary for the development of the jaw. Further, the weanling needs the right kind of fat to avoid rickets and other developmental disorders.

The campaign in Shropshire, which has been conducted by the Education Committee since 1911, has been founded chiefly on Dr. Wheatley's first two points. The main theme of the leaflet issued is that if starchy or sugary food can be prevented from sticking to the teeth there will be no decay, and the advice is on the following lines: 1. The giving of food to the weanling and little child that will need mastication; the avoidance of pappy foods, and of drinking between mouthfuls of food. 2. Sweets never to be given between meals, or as the last food of a meal. 3. Each meal, especially the last of the day, to be finished with a tooth-cleansing food. A list of starchy, sugary and tooth-cleansing foods is given at the foot of the leaflet. The Derbyshire Education Committee issues similar advice in the form of a card. In the paper already mentioned Dr. Wheatley makes a strong plea for the Ministry of Health to lead a national campaign against dental decay founded on our present knowledge, and to place the cause and prevention of dental caries in the forefront of its scheme of research work in order to clear up points of doubt.

Let no one think the campaign will be a small affair. It sounds simple—to keep our teeth free from starch and sugar between meals, and so get rid of perhaps the greatest cause of ill-health and inefficiency, but we shall be up against ingrained habits and pleasures. Anyone whose recollections go back 40 or 50 years knows how enormously the habit of sucking sweets has grown during that time. It may be argued that a habit which has increased so rapidly may decline as rapidly if good reasons can be given against it: but the reasons must be good ones, the Ministry of Health will have to give an effective lead, and medical practitioners and dentists present a united front.

THE SWIMMING BATH AND CATARRHAL OTITIS.

DR. K. Amersbach,[1] director of the University clinic for diseases of the ear, nose, and throat at Freiburg in Breisgau, remarks that though swimming-bath conjunctivitis was described as long ago as 1899 no connexion has hitherto been suspected between this condition and disease of the ear. Recently, however, during an outbreak of swimming-bath conjunctivitis at Freiburg numerous cases of catarrh of the Eustachian tube were seen at the out-patient department of the clinic. The patients chiefly belonged to a swimming club, and most of them were also suffering from conjunctivitis. The most striking feature about the tubal catarrh was its obstinate character and tendency to relapse. In almost all the cases the ear trouble developed about a fortnight after the onset of the conjunctivitis. The patients complained of a feeling of pressure in the ear, tinnitus of varying degree, autophony, and more or less impairment of hearing. The drum-membrane, which was otherwise quite normal in every case, was drawn

HEALTH OF LONDON SCHOOL CHILDREN:

REPORT FOR 1920 OF THE SCHOOL MEDICAL OFFICER, L.C.C.

VOLUME III. of the annual report of the London County Council, which has just appeared, may be obtained from P. S. King and Son, Ltd. (No. 2104. Price 2*s.* 6*d.*). It contains in two parts the public health reports of Dr. W. H. Hamer, County M.O.H. and S.M.O., the second and longer part being headed "Education." It is this chapter which is here briefly summarised. The report, it may be remarked, has high literary merit and contains dissertations and digressions of a technical nature which add greatly to its interest.

General Progress.

Dr. Hamer opens with the statement that the results obtained during 1920, so far as school medical work is concerned, were favourable beyond all expectation. The figure of 76·9 per cent. of children found satisfactorily dealt with up to the time of the second re-inspection is the highest on record since the Council undertook to provide treatment for ailing children. In respect of physical conditions the great gains claimed during the year are those accruing from (*a*) medical oversight of continuation school young persons and of children coming within the scope of the new by-laws as to employment; (*b*) extended medical treatment scheme affecting elementary school children, secondary school children, and any young persons unable to obtain treatment save under the Council's scheme; and (*c*) materially improved methods of cleansing now being put into operation throughout London.

Tonsils and Adenoids.

An interesting event was the opening of a centre in Woolwich at which children operated upon for enlarged tonsils and adenoids are kept for two days subsequent to operation. After discharge from this special centre each child returns to the local centre for breathing exercises under the supervision of his own surgeon until finally discharged as cured. This is a great advance, as the results of these operations in out-patient departments without after-care have been unsatisfactory. It would be interesting to learn what interval usually elapses between the operation and the final discharge as cured, and whether the patients discharged as cured are able to breathe comfortably through their noses both when awake and asleep.

Nutrition, Cleanliness, Teeth.

Medical inspection during 1920 revealed a slight improvement in clothing, a continuation of the deterioration in nutrition which was noted in 1919 (following the war years during which there was a notable improvement), and a continual steady improvement in cleanliness. There has been, Dr. Hamer writes, a 30 per cent. improvement in seven years in verminous conditions, and this improvement has been accelerated during the last three years, during which a great forward campaign against infestation by vermin has been going on since the Council made addition for the purpose to the personnel of the school nursing staff.

Slight ground is said to have been gained as regards dental conditions. The report recognises the immense problem that remains to be solved. Forty-six dental centres have been provided and are working at full pressure, and although the numbers of children at the older ages with serious dental caries have been halved since provision for treatment began to be made, yet 40 per cent. of the children leaving school still have obvious dental caries. "Now," Dr. Hamer writes, "dental decay is held by all to be a preventable disease, and it is clear that in order to cope with this great mass of trouble all the aid that can be given by education and the practice of hygiene must be pressed into the service. Not by treatment of the worst cases, but by prevention at the outset, will success finally be achieved." No practical suggestion is offered in regard to prevention, and the report possibly does not mean us to infer that there is general agreement as to how dental decay is to be prevented.

Open-Air Education.

A hopeful account is given of the treatment of suppurating ears by ionisation. Satisfactory results are reported from the classes for stammering children. The difficulties encountered in following up children suffering from defects are set out at some length. Some interesting notes by Dr. C. T. Thomas on the medical examination of school children employed in entertainments are given. Definite progress has been made during the year in the provision for open-air education. During 1920, 2700 boys were admitted to the King's Canadian Camp School, Bushy Park (opened in August, 1919), with satisfactory results. Wanstead House Camp School, accommodating 64 girls, was opened in August. Of the 2000 places in open-air day schools estimated to be required in London for non-tuberculous children, 410 places have been provided and 600 are proposed; of the 2000 places needed for tuberculous children 290 have been provided and 100 are proposed.

We agree with Dr. Hamer that these open-air schools should not be closed for the summer holidays, "just at the time when the maximum benefit is being received by the children." In addition to the open-air schools, much good work has been done for ailing children by the establishment of open-air classes in connexion with elementary schools.

Physical Culture.

A noteworthy event of the year has been the establishment of a College of Physical Education for London teachers. Facilities for attendance at the College have been offered to teachers in the service and accepted by large numbers, so that ere long the effect of the College will show itself in improved physical training at the Council's schools. Special classes in physical exercises for children suffering from incipient deformities have given good results during the last few years, and it is hoped to increase the number of such daily classes to 100 during the coming year. An experiment is recorded at Vauxhall Street School, where the head teacher has endeavoured to found all the educational activities of the school upon a basis of physical training. The effects were shown by increased attendance and by the physical, moral, and mental improvement of the scholars.

There has been a considerable increase in the provision of meals as compared with the previous year. Thus in the last 12 school weeks of 1920, 191,514 elementary school children were fed, as compared with 113,747 during the corresponding period of 1919.

Dr. A. G. Wells deals with the difficulty of "diphtheria carriers," and is inclined to favour the view that the rules as to their exclusion from school may have to be relaxed. Other matters of interest dealt with are "School Holidays in Relation to the Spread of Scarlet Fever and Diphtheria," "Scarlet Fever and Diphtheria in Relation to Flea Prevalence," and "Diagnosis of Mental Defect."

The report is a record of useful work and progress during a year in which the general death-rate and infant mortality of London were lower than ever before.

WATER-SUPPLY FOR CARAVANNERS.—A Cheshire farmer was summoned at Birkenhead last week for failing to provide a sufficient supply of wholesome water to a caravanner who was renting a field from him. The obligation rests on a by-law made by the Ministry of Health under the Housing of the Working Classes Act, 1885. As it was the first case of the kind the farmer was let off with the payment of costs.

Committee organised in Paris. According to these statistics, the situation, especially as regards epidemic diseases, would appear to be less serious than some reports have stated. Officially there are 36,000 cases of cholera, of which 60 per cent. are in the towns. The typhus incidence has continued to fall throughout the summer, though it may be expected to rise again next winter. Although plague is rife in Persia, a strong sanitary cordon has up to the present preserved the immunity of Russia. As regards the famine it is stated that the annual excess of production of corn over the need in the Volga district amounting normally to 60 million poods, has this year been converted into a deficiency of the same amount; 120 million poods are therefore needed to meet the famine requirements. 150,000 people have left their homes. Of these 50,000 have been "repatriated" into Siberia and are now stabilised. The remainder will be "repatriated" into the less necessitous districts.

The resolutions adopted by the Geneva conference provide for the creation of a relief commission to coördinate the action of the official and voluntary relief agencies. In view of the magnitude of the task, emphasised by Sir Claude Hill, who has had experience of two serious famines in India, the coöperation of all governments was considered essential. The commission will therefore consist of delegates from governments as well as from Red Cross societies and voluntary associations. Dr. Nansen, Mr. Hoover, and a representative of Mr. Hoover nominated by him, were appointed high commissioners, with full authority to make the necessary preliminary agreement with the Soviet Government concerning the administration of relief. Dr. Nansen has already telegraphed his acceptance of this post. The Commissioners are instructed to work in close coöperation with the Russian Government and Russian voluntary organisations.

LATE EFFECTS OF GASSING OR TUBERCULOSIS?

Dr. J. B. Hawes has an important article on this subject in the *Boston Medical and Surgical Journal.* He points out that while we know a great deal of the immediate effects of the gases used in the late war, we know little of the late effects. We know that they have irritative and escharotic effects on the respiratory tract, and that contraction of the cicatricial tissue produced often leads to serious mechanical difficulties, both in the ingress and egress of air and in the pulmonary circulation. We also know that the gases have a certain selective action. Mustard gas affects chiefly the upper air passages; chlorine injures the entire respiratory tract; phosgene, though least severe in its immediate effect, often leads to serious injury of the lung tissue. The basis of the changes produced by the gases is a proliferative fibrosis, which destroys to a greater or lesser extent the protective powers of the bronchi, and leads to invasion by organisms. While tuberculosis may play a part in the invasion it is, in Dr. Hawes's opinion, a very minor one. The X rays show a characteristic picture—increase in the tissues round the hilus, especially peribronchial, extending towards but rarely into the parenchyma of the lung, and more towards the bases than upwards. The apices are usually clear. There are often localised areas of fibrosis. The signs and symptoms form two groups—pulmonary and constitutional. Among the first are cough, expectoration, hæmorrhage, pain, or a sense of constriction of the chest; dullness, usually at the bases and due to thickened pleura; diminished voice and breath sounds; râles of every variety. Among the second are loss of strength, shortness of breath, and a psycho-neurosis (a tendency to exaggerate symptoms with increased reflexes). Fever, wasting, anæmia, and other symptoms characteristic of tuberculosis are absent. Yet in Dr. Hawes's experience the majority of the cases are diagnosed as tuberculous. Another characteristic of these cases is sudden acute febrile attacks, often without cough or sputum, which disappear as suddenly, leaving intense lassitude for a considerable time. Out of 35 men definitely diagnosed as tuberculous, or suspected to be so, Dr. Hawes could confirm the diagnosis in only 8. Localised dullness with or without sticky râles at the bases of the lungs was the striking feature of physical examination. Additional evidence against tuberculosis was that the sputum was constantly negative for the bacillus. The treatment does not differ much from that of pulmonary tuberculosis, except that the patients should not be sent to a sanatorium or hospital. Dr. Hawes recommends rest away from a medical atmosphere, and sympathy and encouragement. These bring about the best results.

GERMAN NAVAL HYGIENE.

BEFORE the war the publication of the annual health report of the German Navy was quite an event for students of naval hygiene, as it always had an article stating the more important hygienic advances made during the year in the ships, and no other such article was published elsewhere. These reports were always published late, not, like those of the British Admiralty, shortly after the end of the period, and the books for 1911–14 have only recently come to hand; but they still have interest. In 1911–12 officers were again being accommodated aft in ships. Ozonisation of the air continued to give satisfaction. Low-pressure steam was preferred for heating, and radiators were being fitted that could be easily cleaned, to avoid the scorching of adhering dust, which causes smell. Electric heating was only employed in U-boats and in the Kaiser's suite in the new *Kaiser* battleship. Ice machines were being installed, and more refrigerating chambers permitted the men's food to be oftener fresh. When biscuit had to be issued it was made into puddings. Bakeries were to be on the upper deck in future. Men of the High Sea Fleet at sea usually drank 5 oz. of beer, each of them, daily. Other drinks like lemonade, Maggi's consommés, and cocoa were offered them in the canteen to wean them from beer. The widespread but evil habit of cigarette-smoking had spread so far that men took up on an average two cigarettes each per day, besides what they brought on board, but canteens sold chocolate, sweets, and buns cheap, which reduced tobacco sales. Nearly every man had a wash-hand basin of his own which he kept in his locker, consequently boils were fewer. Seamen used the stokers' bathroom one day a week, and the canvas bath was constantly rigged on deck. Permanganate solution was regularly issued as a mouth-wash; water was replacing oil in the sparge pipes of urinals. A second X ray apparatus was intended to be sent afloat, the first, in *Deutschland*, having been a success. U-boat crews got four weeks leave in the year (others probably only a fortnight). On hot stations men were allowed to sleep on deck, but they must wear night clothing with cummerbunds, and fruit was rarely allowed on board unless it could be dipped first in boiling water to sterilise its exterior. Extra closets were being fitted in ships with dysentery cases to secure isolation and lessen infection. At Tsingtau vessels under refit were disinfected, cleaned, and aired. At the Litsun dispensary at Tsingtau there attended 4254 Chinese out-patients.

In 1912–13 attention was being given to protect cabins and sick bays against heat and noise. Sick bays were to have a system of ventilation of their own, with supply and exhaust, independent of the ship's system, to keep them sweet though ports are closed in a sea-way. Metal filament lamps were being used to improve lighting. In the *Kaiser* class fresh water was piped to kitchens, bakeries, lavatories, and sick bays; individual wash-basins were being further issued, and tiles for bathrooms were approved. The canvas bath was constantly used. One ship fitted a steam hose, and in so doing was able to begin swimming instruction in the bath in May and taught far more tuberculosis may have a 33 per cent. chance of recovery, maintained for several years, if his artificial pneumothorax is big enough. But, as Dr. Saxtorph's figures suggest, a small, partial pneumothorax may even do more harm than good by keeping diseased foci in the lungs in a state of tension.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Treatment of Encephalitis with Pregl's Solution of Iodine.

AT a recent meeting of the Vienna Medical Society Dr. Dattner reported on the results obtained by the administration of the new iodine combination worked out by Professor Pregl, of Graz. This solution was said to give off pure iodine in tissues pathologically changed. The results obtained in other places had been so satisfactory that the Vienna Clinic for Neurology was prompted to test the substance on cases of encephalitis lethargica; the cases were all of the acute type, and the effect was observed very shortly after the injection. The treatment consists of intravenous injection of large doses—100 to 300 c.cm. —up to a total of 1500 c.cm. of the liquid. Some of the cases had been treated without effect with urotropin and methylene-blue. The changes produced by the injections were: disappearance of the drowsy condition, of the Kernig's symptom, and gradual restitution of normal health. In chronic cases the disease (e.g., of the trophic centres) was of too long standing for much benefit to be obtained. In one case the patient was up and about again after 24 hours. The disadvantages of the injection are sometimes slight pain and urticaria, and sometimes thrombosis of the veins. It is advisable to use a large needle and syringe, as the liquid is rather viscous. The investigations suggest that the solution is, if employed early, a useful remedy against encephalitis. At the same meeting Dr. Hauer was able to report on the value of the same solution in dental work, for which it was originally intended. He used it in alveolar pyorrhœa, in implantations and re-implantations of teeth, and in operations on the maxillary antrum, with regular success as regards rapidity of healing.

The Results of Famine Relief amongst Children.

The chief officer of the Vienna Board of Health, Dr. Böhn, reported recently to the Medical Society on the results of the public feeding of children in this city. Of 195,000 children attending the public schools, no less than 171,000 were examined. Only 15 per cent. were found in January, 1920, to be normal in physical development, 40 per cent. showed more or less marked deficiency in weight and body measurement, whilst 45 per cent. were classified as severely underfed and lacking in development of bones. By the work of an excellent organisation, which ensured that each child really got the meal intended for it and really partook of it, the general condition of the prospective candidates for tuberculosis was so altered that they could overcome the latent tuberculosis from which the majority of them were presumably already suffering. The enterprise of English and American philanthropists has saved thousands of children in Central Europe from starvation. A few figures will help to show the actual situation: In 1912, the number of deaths in Vienna was 32.141; in 1918 it rose to 51,497. In 1919 it fell to 40,932, and in 1920 there was a further drop to 34,197. The drop is chiefly due to the saving of life in the age-periods from 5 to 15 years. Deaths from tuberculosis numbered 6358 in 1912, 9809 in 1918, and 7132 in 1920. The rapid recovery in general health, evidenced by the falling mortality figures, is ascribed mainly to the improvement in their nourishment aided by the temporary expatriation of so many children under the care of English, American, and Dutch committees. In 1920 42,000 children at a time were boarded out in Holland, Switzerland, Italy, and England. Institutes for the care of rachitic and tuberculous children were substantially aided by grants and gifts from abroad. At the height of the relief activity 29 central kitchens were engaged in the preparation of the 150,000 portions of meals required daily. Each portion contained the food value of 500 nem for infants, 1000 nem for school children, and 1500 nem for juveniles up to 16 years. The places of distribution numbered 534 in Vienna; throughout Austria 400,000 portions were distributed daily. The children were subject to repeated examinations, the last one taken in the winter 1920–21 comprising all the children fed by the famine fund. The increase in weight and length was on an average 5 per cent., but in many cases was as much as 12 per cent. The number of children to be classified as underfed has dropped to 22 per cent., whilst the number of well-fed has gone up to 35 per cent. of the total; the remainder are described as approximately normal—in short, an excellent result. Similar investigation of juveniles (14 to 16 years) is now going on, and the results will be published.

Unveiling of Tablet to Politzer.

On the anniversary of Prof. Politzer's death—the famous otologist was indirectly a victim of the deplorable conditions prevailing last year in our public life—a commemorative tablet was unveiled, in the presence of many of his friends and former pupils, in the lecture-room of the Vienna Otologic Clinic. Representatives of many German and American learned societies testified to the esteem which the deceased had commanded all over the world. Docent Dr. Ruttin formally accepted the tablet on behalf of the clinic.

Appointment of Prof. Kermauner.

With the appointment of Prof. Kermauner to direct the second gynæcological clinic (Prof. Peham is the head of the first clinic) an unsatisfactory state of affairs has been terminated. For more than a year students of gynæcology and obstetrics have had no instruction from a fully recognised first-class teacher; during Prof. Wertheim's illness both clinics lacked responsible guidance.

Drought and the Water-supply.

For some weeks the city of Vienna has enjoyed not only the benefits of a tropical heat but also an abundant supply of excellent water. The result is that the public health reports show a marked drop in the incidence of disease and in mortality. Catarrhal conditions of the respiratory organs are practically unknown at present, deaths from tuberculosis are comparatively few, and even the gastro-enteric conditions so often associated with summer heat are not as bad as in former years. It seems that the continuous sunshine has destroyed or weakened the toxicity of the microbic infection, whilst the wholesome water-supply increases the resistance of the individual. The water is obtained from the Alps, at a distance of some 150 miles; for each person in Vienna 100 litres a day is provided. Vienna is now perhaps the best supplied large city in the world as regards the purity and temperature of its water-supply. The only drawback of the heat wave is the fact that a large proportion of the milk arrives in a sour condition. Lately over 40 per cent. of the milk-supply was sour, and condensed milk had to be widely distributed amongst weanlings.

August 12th.

IN response to an appeal by the chairman of the board of the Bradford Royal Infirmary, a donation of £1000 has been sent by Mr. W. H. Shaw, of Bradford, for the purchase of an X ray plant for the treatment of internal malignant disease.

as light as ordinary coal gas. Helium is very widely distributed in nature, it is present in minute proportion in the atmosphere, and occurs to the extent of 1·5 per cent. or more in the natural gas of Kansas. It is vastly safe as a buoyant agent, for it is not only non-inflammable, but it has hitherto resisted every effort to make it combine with other elements. The terrible disaster will not sound the knell of the airship or prevent men from risking their lives in its further development, but it should and must turn the minds of our rulers to insist on every avenue of safety being explored, even if helium has to be fetched from America and new engines designed to consume heavier fuel.

SYPHILIS IN THE NEGRO.

Dr. Ernest L. Zimmermann,[1] of Baltimore, has undertaken a comparative study of syphilis in whites and negroes for the purpose of emphasising inherited racial differences in response to syphilitic infection. The paper is based on the study of 1843 cases in the Johns Hopkins Dispensary, a charitable clinic in which approximately 60 per cent. coloured and 40 per cent. white patients are treated. The race and sex distribution of the cases was as follows: 596 white males, 521 coloured males, 297 white females, and 429 coloured females. It was found that in negroes a much greater number of infections occur before the twentieth year than in whites. Over 50 per cent. of the female patients become infected before their twenty-first year, a fact explained by their early indulgence in promiscuous sexual intercourse, the greater frequency of syphilis in the negro race, and the sexual indulgence of the negro male in spite of the presence of primary or secondary lesions. No differences were noted in the character of the chancre in the two races, the more pronounced induration described by Morrison in the negro not being observed. Dr. Zimmermann's experience confirms that of other writers as to the rarity of extragenital chancres in the negro, only 5 out of 27 such chancres in this series being found in coloured patients. Secondary syphilis in the negro was characterised by marked polyadenitis, frequent and severe osteoarthritic symptoms, by the frequency of iritis, and by the high incidence of follicular and pustular syphilides. Though secondary lesions of the mouth and pharynx exclusive of diffuse erythema were commoner among the white patients, moist papules and condylomata were much commoner in the coloured race, especially in the female. The annular papular syphilide first described by Atkinson in 1882 under the name of syphiloderma papulatum circinatum was unusually frequent in the negro. Tertiary syphilis in the black race was characterised by the predominance of osseous lesions which were twice as frequent as in white patients in whom neurosyphilis was much commoner, and constituted about half of the late manifestations. Cardio-vascular syphilis, as had also been found by Osler and Janeway at the Johns Hopkins Hospital, was relatively more frequent in Dr. Zimmermann's negro patients with an incidence of two to one in coloured and white males respectively. Cerebro-spinal syphilis, including both the meningitic and endarteritic forms, was approximately of equal frequency in both races. Cerebral endarteritis was particularly frequent in black patients, being observed in 20 negroes and in only 9 whites. Tabes was diagnosed in 94 white and in 14 coloured patients, and general paresis in 24 white and only 4 coloured patients. Dr. Zimmermann concludes that there are inherited biological differences between white and negro patients as regards syphilitic infection. The negro develops intense reactions in the cutaneous and osseous structures, and is relatively free from tabes and paresis. In white patients absence of, or only slight development of, skin manifestations is more frequent than in the negro, but there is a greater tendency to tabes and general paresis.

---

THE MAUDSLEY HOSPITAL.

THE third course of instruction for the diploma in psychological medicine opens at the Maudsley Hospital on Monday, Oct. 3rd. On that day, at 2.30 P.M., Sir Frederick Mott gives the first of a series of six lectures on the Pathology of Mental Diseases, and at 5 P.M. Dr. Bernard Hart delivers the first of eight lectures on the Psychoneuroses. On Wednesday, Oct. 5th, at 2.30 P.M., Dr. F. C. Shrubsall lectures on the Practical Aspect of Mental Deficiency, and at 4.30 P.M., Dr. W. C. Sullivan commences a series on Crime and Insanity. On Thursday, Oct. 6th, at 2.30 P.M., Dr. C. H. Bond takes up the Differential Diagnosis and Treatment of Mental Disorders, and at 4.30 P.M. Dr. E. Mapother lectures on the Symptoms of Mental Disease. Six clinical demonstrations will be given on Tuesdays, 2.30 P.M., at the Maida Vale Hospital for Paralysis and Epilepsy, by Dr. F. Golla, commencing Oct. 4th, Sir F. Mott continuing the series. It should hardly be necessary to call attention to the importance of the Maudsley Hospital as a school of psychological medicine. In line as it is with the forward movement in mental medicine on its preventive side, this institution cannot be allowed to fall a victim to the very natural spirit of economy at present prevailing at the London County Council. Medical men in London will lose no opportunity of making their opinion effectively known in this regard.

EXPERIMENTS ON LIVING ANIMALS.[1]

UNDER this title a return has been issued over the signatures of Sir George Thane for England and Scotland, and of Dr. M. C. McKenna for Ireland. Full details are tabulated of the places registered for vivisection, of the licensees with their qualifications, and of the number and nature of the experiments performed. Sir George Thane in his report makes it clear that the utmost precautions must be taken by investigators to avoid pain and sepsis, not only in the interests of the animals, but in order to ensure successful results. It is unnecessary here to set out the limitations imposed on licensees working under the various certificates issued, as medical men are well aware of the strict supervision of all biological research. Most workers will have received unexpected visits from inspectors, and the tribute paid to licensees for their attention, not only to the actual requirements of the Act but to the suitable lodging and general well-being of the animals, will be received with satisfaction. Seven technical irregularities only are noted, six due to inadvertence or misapprehension, and in the seventh case only, where experiments needing Certificate B were performed by a licensee holding only Certificate A, was the outstanding application for the required certificate refused. Distortion of the true facts relating to experimental medicine can best be refuted by reference to official statements, and an accessible copy of the current report might well be on the medical man's bookshelf.

Sir Walter Fletcher will preside over the Section of Physiology of the British Association to be held at Edinburgh next week and will speak on the part played by physiology in the war.

---

[1] H.M. Stationery Office. Price 6d.

RADCLIFFE INFIRMARY, OXFORD.—The successful post-graduate course held in October last year is being repeated this year from Oct. 3rd–8th. The subjects for discussion include the Cause of Diseases of Joints (Sir A. Garrod), Modern Views of Heart Disease (Dr. W. Collier), Some Cases in the Later Stages of Syphilis (Dr. E. Mallam), while the surgeons will operate at stated times, and demonstrations will be given in the wards and special departments. Dinner in Queen's College Hall on Saturday evening completes the week. Further information from Dr. Hugh Whitelocke, Secretary to the Committee, 6, Banbury-road, Oxford.

Public Health Services.

Size of Panel Lists.

THE prevalent notion that the average number of insured persons on a panel practitioner's list runs into thousands is dispelled by the figures given in the Health Minister's report. The regulations now, of course, impose a limit of 3000 as the absolute maximum for a doctor working single-handed. In one-third of the English areas the maximum is fixed at 2500 or under. On Jan. 1st, 1921, about 34 per cent. of insurance practitioners had less than 600 names on their lists, another 30 per cent. had between 600 and 1200, 22 per cent. had between 1200 and 2000, and only the remaining 14 per cent. (numbering some 300 doctors) had upwards of 2000 names. In the last group in many cases an assistant is employed.

Consultant Service in Wales.

Generally speaking rural areas are badly served with consultant advice, and the memorandum prepared by Dr. Ewen J. Maclean on the position of Wales in this respect is of interest at this juncture. The note appears as an appendix to the second report of the Welsh Consultative Council, to some aspects of which we have already called attention. In a mixed urban and industrial area, Dr. Maclean estimates that there may be 2000 inhabitants to one general practitioner, and 45,000 inhabitants to one consultant, using the term to include specialists as well as physicians and general surgeons in practice as such. He traces the natural history of the consultant, recording his own opinion that the competitive element in his career is of advantage alike to himself and to his patients. The number of consultants is necessarily proportionate to the number of status-giving hospitals, general and special, and the number of hospitals is grievously deficient in Wales, apart from Cardiff and Swansea. Facts brought to public notice by the School Medical Service, and by the Naval and Army Services during the war, have, in Dr. Maclean's opinion, produced a popular demand for extended preventive and curative treatment and therewith for more consultants. Under present circumstances therefore the customary long waiting period and its associated struggle for existence might with advantage be curtailed or eliminated. The cost of adequate whole-time salaries for all consultants is regarded as prohibitive, even if desirable, and remuneration is suggested on a part-time basis, with extra fees for special visits and certain operations. The memorandum has a close bearing on the National Health Institute and the four Central Institutes—namely, at Bangor, Wrexham, Swansea, and Newport—suggested as part of a complete scheme of medical and allied services for the Principality.

Canal Boat Hygiene.

The second annual report of the Ministry of Health has little fault to find with the habits of canal boat dwellers, a class not generally associated with any particular regard for hygiene. On the occasion of more than 19,000 inspections by Mr. Owen J. Llewellyn during 1920, boats were found without infringement of the Canal Boats Acts. In the same period 2182 delinquencies were found on 1602 out of a total of about 6000 boats, most of these of a trivial or formal character. Very few cases of overcrowding were found or of imperfect partition of cabin accommodation between the sexes. In a year's time, when the recommendation of the Departmental Committee to prohibit children of school age from living aboard during term-time comes into force, any occasion for overcrowding will be still further diminished.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Dewsbury.

Dr. O. M. Holden gives the Registrar-General's estimate of the population as 55,080. The birth-rate has gone up from 19·0 in 1919 to 23·07 in 1920. The death-rate was 14·23, "the lowest recorded since amalgamation." The infantile mortality, 110, is "still high," 69 of the 140 infant deaths occurred in the first four weeks of life; there were 56 stillbirths, being 4·2 per cent. of the total births. The maternal mortality in connexion with childbirth seems to have been high during the last six years. Dr. Holden reports a serious dearth of properly trained women to act as midwives in the borough; doctors are compelled to fall back upon the antiquated and unsatisfactory method of "handywomen" help. During 1920 the qualified midwives only attended 460 out of 1271 births, or a little more than one-third. In most industrial towns the proportion is more like two-thirds. "The chief occupations (of Dewsbury) are those connected with heavy woollen goods, coal, rags and rag flock, glass blowing, &c." Of 14,060 dwelling-houses, 4450, or 31·65 per cent., are "back-to-back" houses. Dr. Holden, of course, condemns the privy-middens and large ashpits. There are still 2374 privies. The number converted in 1920 was 102. It is to be hoped that the rate of progress will be increased in subsequent years.

Eighty-six observations of smoke emissions from mill chimneys were made, and 24 statutory notices served, but no mention is made of proceedings. Anything beyond a minute or two in the hour of black smoke from a mill chimney is quite inexcusable and a vigorous anti-smoke campaign is urgently needed in these mill districts.

The tuberculosis death-rate was not high, 0·671 for pulmonary tubercle and 0·255 for "other forms," giving a total of 0·92. The rates from 1911 to 1920 indicate that there was no war increase of tuberculosis in Dewsbury (though there has been a decrease since the Armistice). Is this because the war work of Dewsbury was its ordinary work, which included coal-mining, an industry little liable to tuberculosis?

Twenty-one cases of ophthalmia neonatorum were notified. One case died while the eyes were under treatment, in another the right eye was damaged, the eyes of the other 19 cases were ultimately found to be quite clear. Dr. Holden reports a considerable shortage of houses of the smaller type suitable for the average labouring class family. Owing to unemployment, families which applied for corporation houses a year or so ago now find themselves unable to afford them. Owing to high prices war arrears of repairs have not yet been made good. Dr. Holden wants legislation to strengthen the hands of sanitary authorities against careless and dirty tenants.

Tottenham.

The population of Tottenham Urban District in 1920 was estimated to be 156,020, the birth-rate was 26·04, the death-rate 9·3, the infant mortality rate 61·0, and the phthisis death-rate 0·85. Dr. David C. Kirkhope tells us that the infant mortality rate is the lowest on record. He also says: "At the end of the year the housing scheme, both at the Coombes Croft site and the Devonshire Hill site, had been commenced. So many inhabited houses had, during the war, fallen into a condition of serious disrepair, and even dilapidation, that arrears of sanitary reform have by no means been made up . . . ." and "The methods employed in Tottenham for the disposal of refuse leave much to be desired and it is to be hoped that the problem will receive early consideration and be met with an adequate solution." Under the heading ophthalmia neonatorum, we read: "Thirty-two cases were recorded during the year. These were promptly followed up. In one case, notwithstanding that the child was under medical care, the sight of both eyes was lost. This is the only instance of permanent injury resulting from ophthalmia neonatorum during the year." We should like to italicise "only," because if every population of 150,000 produced one blind child, the toll of damage from ophthalmia neonatorum throughout the country would be terrible.

The medical officer of health receives the notifications of tuberculosis, but the care of the tuberculous rests

TUBERCULOSIS.

The German Tuberculosis Congress at Bad Elster.

THE reports to hand of the German Tuberculosis Congress, held on May 19th to 21st inclusive at Elster, show that it was well attended, German and foreign visitors numbering about 700. The chief fault found with this congress was the omnipresence of the multiple tautologist. For lack of adequate rationing of these congress pests several delegates with messages to give were crowded out and received no hearing. Congress logorrhœa is a cosmopolitan evil which bids fair to smother medical meetings and to keep away speakers with something new and interesting to say. This state of affairs is the more deplorable as there are certain remedies open to the organisers of congresses animated by the ambition to suppress the congress bore.

In his opening address Kirchner, of Berlin, discussed the influence of the war on tuberculosis, showing how it affected different areas and different age-groups. In an interesting lecture on the part played by domestic animals in the spread of tuberculosis, Prof. Lydia Rabinówitsch referred to studies she had carried out on dogs and cats. Of 19 strains of tubercle bacilli cultivated from dogs, as many as 16 had been found to belong to the human type; only one belonged to the bovine type, and the two remaining strains were of a transitional type. Of five strains of tubercle bacilli cultivated from cats, three belonged to the human and two to the bovine type. Prof. Rabinowitsch was inclined to regard domestic animals as a fairly important source of infection of tuberculosis to man. Papers by Wassermann and Neufeld on immunity in tuberculosis were in a sense discouraging; neither believed in the existence of remedies which attacked the tubercle bacilli in the body, the only remedies which were effective being such as acted on the resistance of the tissues. Friedmann's turtle vaccine did not figure on the programme of the congress, but Klopstock interjected some comments on this remedy, which he had found to be useless in advanced cases and so uncertain in its action in early cases that the results achieved did not bear out the puffs of its promoters. Wassermann referred to it as not only useless but dangerous. Another remedy discussed in unflattering terms was the Deycke-Much partial antigen treatment. Neufeld declared that no experimental evidence had yet been produced in favour of the claim that Much's preparations were superior to other tuberculins, and his "partial antigen laws" were, in Neufeld's opinion, quite "up in the air" and bereft of any scientific foundation. Prof. Uhlenhuth's advice was to the effect that research in chemotherapy should be pursued, as he believed in the possibilities of destroying the tubercle bacillus in vivo by chemical agents. On the other hand, the most authoritative speakers adopted a sceptical attitude towards the possibilities of destroying the tubercle bacillus in the body by immunobiological methods. Perhaps the most useful function of this congress was the opportunity it gave leaders of the medical profession in Germany to chart for the benefit of their colleagues the blind alleys of the problems of tuberculosis.

Annual Report of the Trudeau Sanatorium.

The thirty-sixth annual report for the year ending Oct. 31st, 1920, is, like its predecessors, stimulating and hopeful without being heady. More and better work has been done than heretofore, an endeavour has been made to employ more exact methods in treatment and diagnosis, and every advance in clinical or laboratory work has been weighed carefully in its potential relations to the patient. By keeping up to date with the study of tuberculosis research all over the world the medical officers of the sanatorium are able to correlate their own investigations with research elsewhere, and by their system of coöperative and collective study they have rendered the diagnosis of tuberculosis untenable in an increasing number of cases. "The diagnosis of pulmonary tuberculosis, curiously enough, grows more instead of less difficult as time goes on." At the Trudeau laboratory, S. A. Petroff has nearly completed his researches into the distinctive features of different groups of the human tubercle bacillus, and he is also engaged in studies in iso-agglutination of the blood and the clinical value of the complement-fixation test. The value of acriflavine has been studied experimentally, and while found to prevent growth in the test-tube, it apparently hastened the death of the animals. Extensive studies have also been carried out on the value of vitamins in the tuberculosis of rats, and experiments have shown that the bovine tubercle bacillus grows best with vitamin B, the human type with vitamin A. Healing of tuberculosis being in part due to the deposit of lime salts about the tubercles, the laws governing such a deposit have been studied, many patients have been treated with an excess of lime salts in the form of calcium lactate, and the results obtained are shortly to be published. Equipment has recently been provided for a study of the basal metabolism in tuberculosis and for complete chemical examinations of the blood. Since the recent introduction of diagnosis of intestinal tuberculosis by the X rays, more than 700 cases have thus been investigated, and 5 or 6 per cent., some without clinical evidence of intestinal tuberculosis, have been found to suffer from this complication. "Our methods were studied to see if we could dispense with the X ray work in the diagnosis of this condition, but it was found impossible to make a definite diagnosis without it." Since the Trudeau Sanatorium was opened in 1884, 5586 patients have been admitted, and for the past 18 years an attempt has been made to communicate with each discharged patient each year. In 1920 only 5·5 per cent. of all the patients ever admitted to the sanatorium remained unaccounted for, and an analysis of 4975 patients, treated up to Oct. 31st, 1919, showed that 2240 were alive and well, 578 were alive but ill, 1894 were dead, and 263 could not be traced. The moral of this report is that a sanatorium which is inspired by restlessly dynamic forces can not only treat tuberculosis successfully, but may also advance our knowledge of the genesis of this disease.

Late Results of Pneumothorax Treatment.

Two of the most common and plausible objections to pneumothorax treatment are that its benefits are only palliative and evanescent, and that while it may be recommended to the "idle rich," it is unsuited to the working-class patient whose survival depends on his ability to support himself. In a recent paper Dr. S. M. Saxtorph[1] of the Danish Nationalforenings Sanatorium at Nakkebollefjord has attempted to meet these two objections by showing that, even several years after discharge, a considerable proportion of working-class patients treated by artificial pneumothorax may still be fit for work. This treatment has been adopted at Dr. Saxtorph's sanatorium for over ten years, and his paper deals with 200 patients whose disease qualified them for pneumothorax treatment. They were classified according as (1) a pneumothorax could not be induced, 58 cases; (2) only a partial pneumothorax could be induced, 34 cases; and (3) a complete pneumothorax could be induced, 108 cases. Two years or more after the discharge of these patients it was found that of the 58 in the first class 47 were dead, 6 were alive but unwell, and only 5 were fit for work. Of the 34 patients in the second class only 3 survived, and of these only 2 were fit for work. But of the 108 patients in the third class, in which the pneumothorax was comparatively large and unlimited by other than slight apical adhesions, 34 were alive and for the most part fit for work two to six years after discharge. It appears from these figures that a working-class patient in the third stage of pulmonary

---

VITAL STATISTICS OF LONDON, JULY, 1921.

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 10·3 per 1000 of the population, estimated at 4,531,971 persons in the middle of 1920; in the three preceding months the rates had been 8·7, 9·6, and 9·4 per 1000. Among the metropolitan boroughs the lowest rates from these diseases were recorded in Paddington, Chelsea, St. Marylebone, Hampstead, Holborn, and Wandsworth; and the highest in Stoke Newington, Finsbury, Shoreditch, Stepney, Bermondsey, and Woolwich. The prevalence of enteric fever was somewhat greater than in the two preceding months; of the 32 cases notified during the four weeks ended July 30th, 5 cases belonged to St. Pancras and 4 to Wandsworth. There were 27 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 10, 18, and 23 at the end of the three preceding months; the weekly admissions averaged 5, against 2, 5, and 4 in the three preceding months. The prevalence of scarlet fever was about 12 per cent. greater than in the preceding month; this disease was proportionally most prevalent in Stoke Newington, Finsbury, Shoreditch, Stepney, Bermondsey, and Woolwich. The Metropolitan Asylums Hospitals contained 3722 scarlet fever patients at the end of the month, against 3217, 3375, and 3621 at the end of the three preceding months; the weekly admissions averaged 567, against 411, 507, and 506 in the three preceding months. The prevalence of diphtheria was slightly greater than in the preceding month; the greatest proportional prevalence of this disease occurred in Hackney, Finsbury, Shoreditch, Bermondsey, Battersea, and Greenwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 2129, 2121, and 1896 at the end of the three preceding months, numbered 1969 at the end of July; the weekly admissions averaged 250, against 261, 241, and 235 in the three preceding months. Erysipelas was proportionally most prevalent in Hammersmith, Fulham, Finsbury, the City of London, Shoreditch, Southwark, and Deptford. Nine cases of encephalitis lethargica were notified during the month, against 77, 56, 24, 14, and 18 in the preceding months of the year; of these, 2 belonged to Southwark. The notified cases of cerebro-spinal fever numbered 7, against 12, 11, and 5 in the three preceding months; of these, 2 belonged to Lambeth. The 30 cases of puerperal fever included 6 in Islington, 3 in Fulham, and 3 in Stepney.

The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ended July 30th the deaths of 3394 London residents were registered, equal to an annual rate of 9·8 per 1000; in the preceding months the rates had been 12·6, 11·2, and 9·4 per 1000. The death-rates ranged from 6·6 in Hampstead, 7·1 in Fulham, 7·4 in Wandsworth, 7·9 in Hackney, and 8·1 in Battersea, to 11·7 in Finsbury, 12·1 in Stoke Newington, 12·3 in Shoreditch, 12·5 in Kensington, and 13·2 in Stepney. The 3394 deaths from all causes included 247 which were referred to the principal infectious diseases; of these, 3 resulted from enteric fever, 12 from measles, 15 from scarlet fever, 40 from whooping-cough, 53 from diphtheria, and 124 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded in Chelsea or in the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Fulham, the City of Westminster, St. Marylebone, Holborn, Finsbury, and Battersea; and the highest in Hammersmith, Stepney, Poplar, and Bermondsey. The three fatal cases of enteric fever were 2 fewer than the average in the corresponding period of the five preceding years. The 12 deaths from measles were one-fifth of the average; of these, 3 belonged to Stepney, 2 to Islington, 2 to Poplar, and 2 to Southwark. The 15 fatal cases of scarlet fever exceeded the average by 4; of these, 4 belonged to Bermondsey, 2 to Stepney, and 2 to Camberwell. The 40 deaths from whooping-cough were one below the average; of these, 6 belonged to Camberwell, 4 to Islington, and 3 to each of the boroughs of Fulham, St. Pancras, Lambeth, and Wandsworth. The 53 fatal cases of diphtheria were 15 in excess of the average; the greatest proportional mortality from this disease occurred in St. Pancras, Islington, Stoke Newington, Poplar, Bermondsey, Greenwich, and Lewisham. The 124 deaths from infantile diarrhœa exceeded the average by 66; this disease was proportionally most fatal in Hammersmith, Shoreditch, Stepney, Poplar, Deptford.

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING JULY, 1921.

ROUMANIA.

(FROM OUR OWN CORRESPONDENT.)

Anthrax among Animals.

OWING to the uncommon drought this year, and to the consequent insufficient feeding of animals, the number of cases of anthrax is much greater than in corresponding periods of other years. In some parts of the country there is absolutely no grass or water. If the animals do not die of thirst their resistance is so reduced that they readily develop diseases, of which the most prevalent is anthrax. According to Roumanian sanitary law animals suffering from anthrax must not be treated at all, but immediately slaughtered and buried; but the peasants, in order to decrease their losses, take off the hide of the animals, for which they get almost as much as for the animal itself. Many recent cases of anthrax have resulted from this practice. Severe penalties have now been instituted for the infringement of these laws. In one village, near Satu Mare, five animals suffering from anthrax were buried, and the gipsies near the village exhumed the beasts, and ate meat cut from them. Naturally all were taken ill, three of them died, and the rest are being treated in the county hospital.

The late Prof. Genersich.

Dr. Gustav Genersich, professor of pediatrics at the University of Klausenburg (now Cluj), died on July 23rd in his fifty-sixth year. The chair of pediatrics at Cluj was his creation; his name and works are familiar wherever the diseases of children are studied. Prof. Genersich came of a medical family; his great-grandfather was a professor at the University of Vienna, his grandfather a very celebrated practitioner in Hungary, and his father was for more than a generation professor of pathology at the University of Budapest. He himself studied pediatrics at Vienna, Paris, and London. Among his more notable works were the following: "Hereditary Dilation and Hypertrophy of the Colon in Infants"; "Bacteriological Researches on So-called Septic Diphtheritis"; "Remarks on the Practice of Intubation"; "The Influence of the Cradle upon the Development of the Skull"; "On Infantilism"; "On the Spiritual Life of Small Children"; "The Relation of Tuberculosis to School"; and "Official Researches on the Fate of Illegitimate Children." He founded a school for mothers and created an association for the protection of children. During and after the war he turned all his activity towards the care of war orphans, and the considerable decrease of infant mortality in Transylvania is largely attributable to his efforts.

The Unimportance of a Negative Wassermann Reaction.

Dr. Ferencz Veress, professor of venerology at the University of Cluj, says in an article on the above subject that most unfortunate consequences attend the practice of attaching importance to a negative serum reaction. It is still worse if a patient goes directly to a laboratory and not to a specialist. Basing his statement on details of several thousands of cases, he asserts that a positive reaction is the sign of active syphilis, necessitating energetic treatment, but he is emphatic in warning against the drastic treatment of old latent cases of lues, where reaction should be gradually induced by means of mild treatment with mercury or iodine. A negative W.R. alone means nothing at all—the disease may be either non-existent or latent. The reaction can be negative in all stages of syphilis, whether mild or severe. In the estimation of cures clinical symptoms are to be relied upon, but not the negative W.R. It may be necessary to give a course of treatment even when the reaction is negative.

Enuresis and Organotherapy.

Dr. Konradi, specialist in diseases of children, has studied the treatment of enuresis for more than two decades. In 1910 he experimented with organotherapy, employing thyroidin, recommended by Williams, and the testicular extract recommended by Serralach, but was not satisfied with the results, and continued experiments to obtain a reliable cure. He came to the conclusion that the real cause of the disease was insufficiency of the blood-forming organs and endocrine glands, and introduced the application of thymus extract as advised by Ruhra in Baltimore and Firth in London. His results of combined treatment with thyroidin, testicular and thymus extracts leave little to be desired; children suffering from enuresis are given one tablet every day of each, thyroidin, thymus, and testiculin, with rapid and excellent results. Konradi maintains that this effect is a specific one. He had had no case where the three extracts combined did not give good results. In girls, instead of testiculin, ovarial extract is administered. He quotes a case in which a man wanted to divorce his wife on account of her enuresis; by means of his combined treatment Konradi cured the woman and removed all grounds for divorce.

Bucharest, August 18th.

THE HORSLEY MEMORIAL.

THE organisation formed in November, 1920, to secure in permanent form the recognition of the life and work of Sir Victor Horsley has now published a further list of subscriptions, promised and received, as follows:—

	£	s.	d.
Donald Armour, C.M.G., Dr. Ernest Clarke, Colonel Littlewood, C.M.G., W. Rushton Parker, Dr. C. E. Reynolds (Los Angeles), G. E. Twynam .. each	5	5	0
Sir N. M. A. Abbot-Anderson, M.V.O., C. S. Handley each	3	3	0
Dr. C. Bolton, Herbert H. Brown, Captain L. F. Hine, Dr. A. Jones, Edward F. Maynard, Dr. A. McCormick (Sydney), Dr. J. J. A. Neil .. each	2	2	0
Dr. J. Blamey, Dr. C. E. Evans, Dr. J. Lockhart Gibson (Brisbane), Dr. E. G. Goffe, F. P. Mackey, Dr. Nabarro, Prof. J. T. Wilson .. .. each	1	1	0
Dr. L. de Zilwa (Ceylon)	1	0	0
J. W. Papillon	0	7	0
National Hospital (Queen-square)	2	6	5

The total acknowledged in previous lists is £818; these lists appeared in THE LANCET, 1921, Jan. 1st, p. 46, Feb. 19th, p. 407, and May 7th, p. 988.

Further subscriptions, and those promised and still unpaid, will be gratefully received by either of the hon. treasurers, Sir Frederick Mott, K.B.E., Maudsley Neurological Hospital, Denmark-hill, S.E. 5, and Dr. H. H. Tooth, C.B., C.M.G., 34, Harley-street, W. 1, or the hon. secretaries, Sir W. Arbuthnot Lane, Bart., C.B., 21, Cavendish-square, W. 1, and Mr. Edward J. Domville, O.B.E., Symondsbury, Bridport.

JAMES WATSON ALLAN, M.B., F.R.F.P.S. Glasg., lately physician superintendent of the City of Glasgow Sanatorium at Bellefield, Lanark, was recently entertained by the staff of the Public Health Department, who presented him with a silver rose-bowl. Dr. A. K. Chalmers spoke warmly of Dr. Allan's work in building up Glasgow's first great fever hospital.

DEVONSHIRE HOSPITAL AND BUXTON BATH CHARITY.—At the annual meeting an appeal was made for increased financial support, it being pointed out that the total income for the past year was £22,985, or £775 0s. 0d. less than the previous year. Dr. C. W. Buckley, hon. physician to the hospital, called attention to the valuable research work done by the institution in regard to rheumatism. No other hospital in the world anywhere near the size of Devonshire Hospital, he said, was devoted to the work of rheumatic disease; there any method at all worth a trial was tried and tried carefully. The best method of all was the proper use of the Buxton mineral waters, but the literature on the treatment of rheumatism made little mention of the use of the Buxton waters. The work of such institutions as the Devonshire Hospital ought to be better known, and the results of the research work carried out should be widely disseminated among medical men.

Obituary.

HERBERT EDMUND CUFF, O.B.E., M.D. LOND., F.R.C.S. ENG.,

PRINCIPAL MEDICAL OFFICER, METROPOLITAN ASYLUMS BOARD.

A FORTNIGHT ago we briefly recorded the tragic death, at the age of 57 years, of Dr. H. E. Cuff. On the afternoon of August 16th, in an endeavour to save his daughters, aged 15 and 12 respectively, who had got into difficulties while bathing at Burnham Overy on the Norfolk coast, Dr. Cuff was drowned and his children with him.

Dr. Cuff received his medical education at Guy's Hospital, graduated M.B., B.S. Lond. in 1888, took the F.R.C.S. Eng. two years later, and the M.D. Lond. in 1891. After holding resident appointments at Guy's Hospital and at the Leeds General Infirmary, he entered the service of the Metropolitan Asylums Board, and in 1897 was appointed medical superintendent of the North-Eastern Fever Hospital, relinquishing that post eight years later on becoming a member of the head office staff. He became principal medical officer to the Board, devoting his whole time to his office, except for a period during the war when he was resident head of the Belgian Refugee Camp at Alexandra Palace; for this service he was awarded the O.B.E. Dr. Cuff was the author of a number of useful books for nurses, including his reprinted "Lectures on Medicine to Nurses," and he contributed a section on Infectious Diseases to Whiting's "Aids to Medical Diagnosis."

Dr. Lauriston Shaw, one of the medical members of the Metropolitan Asylums Board, writes as follows:—

> In the last few years I have seen a good deal of Dr. Cuff's work as principal medical officer of the Board. Having known him as a student at Guy's I expected to find him able and hard working. But the Board requires other qualities besides these in its P.M.O. In his dealings with the Board itself, its immense staff, both lay and medical, and its numerous and varied types of institution, this officer requires large stores of sympathy, tact, and common-sense, besides technical knowledge of many branches of his profession; all these Cuff had. His earlier work for the Board was carried out solely in the infectious fever service, but this did not prevent him from acquiring practical knowledge of, and maintaining a keen interest in, the various other departments of medical work—mental diseases, eye diseases, tuberculosis, venereal diseases, &c., which have been gradually added to the Board's activities. It was characteristic of Cuff's energy that when the Board was first entrusted with the administration of institutions for the treatment of tuberculosis he spent some portion of his well-earned vacation as locum tenens superintendent of a sanatorium in order to familiarise himself with the special medical and administrative problems of these institutions. It is therefore natural that the Board placed implicit reliance on Dr. Cuff's judgment in the advice he gave it with regard to the constantly recurring medical problems that arose in the course of its ever-extending work. His relations with his professional colleagues administering the institutions and treating the patients therein were as happy as those which subsisted between him and the members of the managing subcommittees. Each section knew that Cuff's advice would be inspired with a whole-hearted desire to do what was best for the afflicted persons entrusted to the Board's care. Though he was always busy he was at all times accessible to those needing his advice or assistance.

Dr. Cuff's sudden and tragic death at the height of his usefulness comes as a severe blow to many beside his associates at the Metropolitan Asylums Board. He leaves a widow whose terrible loss has elicited widespread sympathy.

JOHN WARRINGTON HAWARD, F.R.C.S. ENG.,

CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

WE regret to announce the death in his eightieth year of Mr. John Warrington Haward, consulting surgeon to St. George's Hospital, which occurred on Aug. 20th, at his residence, Manor End, Berkhamsted.

John Warrington Haward was born in 1841, the youngest of the ten children of Mr. James Haward, of Great Baddow, Essex, and entered St. George's Hospital as a student in 1860, when Cæsar Henry Hawkins Prescott Hewett, and George Pollock were the leading surgeons of the institution, and when the demonstrator of anatomy was Henry Gray, whose death occurred from small-pox before he was elected to the staff. Haward was a successful student, being William Brown Exhibitioner in medicine and surgery, and on qualification proceeded to hold the office of house surgeon at Westminster Hospital, and later was resident surgical officer at the Great Ormond-street Children's Hospital. Here, after taking the F.R.C.S., he was elected assistant surgeon in 1870, and his experiences among children dictated his special line of surgical work as far as specialism was then carried in surgery. From 1871 to 1874 Haward discharged the duties of surgical registrar, curator of the museum, and demonstrator of morbid anatomy at St. George's Hospital, and in 1875, on the retirement of Sir Prescott Hewett, whose clinical clerk he had been, he was elected assistant surgeon to St. George's Hospital. He became full surgeon five years later, and he maintained his connexion with the hospital as surgeon, and later as consulting surgeon, until the day of his death.

During this long association with St. George's Hospital Haward gained the respect and affection of generations of medical students by unvarying kindness and courtesy, by the clearness and simplicity of his teaching, and by the high standard of conduct which he manifested—without talking about it. He was ever for essentials in surgery and he arrived on the scene as a hospital surgeon when the essentials themselves were in doubt, and when it was necessary for the teacher both to keep an open mind and to maintain authority; for the year in which he was appointed assistant surgeon to St. George's Hospital marked some of the keenest discussions as to the new antiseptic doctrines. Haward approached the situation from the point of view that caution was the best guarantee for real advancement in learning, and while pleading for the scientific use of the imagination and for the free play of the speculative as well as of the critical faculties, he was never tired of pointing out that the limits and criteria of authority must be considered. This attitude of mind lent to his teaching an old-fashioned flavour which in reality it did not possess; for other of his favourite themes were the value of prevention and the need for early diagnosis, and he advocated these things in words which might express the teaching of to-day. In the operating theatre he was quick to learn the lessons which Lister's discoveries were bringing home to the medical profession, and that he was no mere follower of tradition was shown by his treatise on orthopædic surgery, in which, while declaring that there could be no good reason for the separate practice of orthopædic surgery, he showed that the general body of the profession at his date were not well-equipped in the treatment of many simple cases of deformity.

Haward was a notable figure in the charitable world. He made few public appearances save in the cause of charity, but the esteem in which he was held by his own profession may be estimated by the fact that he had been a Hunterian Professor of the Royal College of Surgeons of England, and President of the Royal Medical and Chirurgical Society, as well as President of the Section of Surgery of the Royal Society of Medicine. He was on the Committee of the Charity Organisation Society, of the Mansion House Council on the Dwellings of the Poor, and of the Invalid Children's Association—of this body he had been president—while he was for a long time Treasurer of the Society for the Relief of Widows and Orphans of Medical Men. Sir Dyce Duckworth, in a letter to us regretting the loss of a life-long friend, alludes to Haward's "skill, wisdom, and high-mindedness," and in those three characteristics sums up the man.

Mr. Warrington Haward married the daughter of the late Dr. James Nicholls, F.R.C.S., of St. Columb, and leaves a widow and two sons. A son who was intended for the medical profession died young.

with the Middlesex County Council, a very unsatisfactory arrangement for a community of the size of Tottenham. The analysis of the infant deaths shows that 112 out of 248, or nearly half, occurred during the first month of life and brings out the fact that, as in other districts with low infant mortality rates, the neo-natal mortality is untouched and the reduction has been in the later months. Dr. Kirkhope draws attention to the need for further accommodation for the dental service and its extension to mothers—expectant and nursing—and to children under 5 years of age.

In his school medical service report Dr. Kirkhope says: "The impression gained by the examination of school children in this area is that the strain of war has left its mark on the 8–9 years age-group. These children appear to be smaller and less weighty than those your medical officers have been accustomed to inspect in previous years." Dr. Kirkhope puts forward as a probable explanation the lack of such foods as butter, eggs, and milk. The need for a skilled aurist to deal with cases of otorrhœa is mentioned. A method of dealing with verminous heads has been developed by which the worst cases of pediculosis capitis can be remedied in half an hour (provided there are no sores on the scalp) without cutting or damaging the hair. School medical officers who are interested should write to Dr. Kirkhope for details. The usual Table V. shows that a satisfactory percentage of treatment is being secured except for dental defects. The report of the newly-appointed dentist, Mr. Sainty, shows that the work was in arrears and also that the percentage of acceptances of treatment is low, seldom more than 45 per cent. for any school. Much propaganda work among parents is evidently required in Tottenham as elsewhere with regard to the importance of dental care and early treatment.

Chelsea.

The estimated population of this metropolitan borough for 1920 is given as 68,500; the birth-rate was 20·3, which is 7·0 greater than in 1919; the infant mortality rate was 52, the lowest ever recorded. Dr. Louis C. Parkes tells us that the maternity and child welfare work grows. The medical staff has been increased. A "home help" was appointed by the Council in October at a wage of £2 for a 44-hour week (with outdoor uniform). The Chelsea Red Cross Nursing Home for Babies, Edith-terrace, was opened in January and is intended for cases of malnutrition, wasting, &c., which are not usually admitted to ordinary children's hospitals. The general death-rate in Chelsea during 1920 was 11·3. The deaths from pulmonary tuberculosis numbered 73 (41 males and 32 females) and of these no less than 71 per cent. died in institutions. Seventeen cases of ophthalmia neonatorum were notified and 3 additional cases of eye trouble in infants were visited. "Of the total 20 cases, 18 made complete recoveries, 1 made incomplete recovery, and 1 infant remained blind of one eye."

Llanelly.

Dr. Laurence W. Pole tells us that Llanelly, the largest town in Carmarthenshire, is mostly situated on low-lying land on both sides of the river Lliedi, which flows into the Loughor estuary forming the southern boundary of the town. The river is polluted before it reaches Llanelly and the tidal estuary is polluted by the sewage and works of the borough. "The country surrounding Llanelly is mainly agricultural and is very beautiful where it has not been defaced by the sinking of coal pits or the erection of factories . . . . The chief occupation of the inhabitants is the manufacture of tinplate." Other industries are iron founding, copper smelting, tin stamping and enamelling, galvanising and de-tinning.

The estimated population for 1920 was 38,776. The death-rate was 12·9 and the birth-rate 21·8. The infant mortality rate was high—viz., 110. The tuberculosis death-rate was also high—viz., 1·23, which is to be compared with 0·88 for 1919. During the last six years there have been more female than male deaths from pulmonary tuberculosis—an unusual occurrence for a town. As in some other towns influenza was prevalent during March and April and 45 deaths were attributed to it during the year. "During the year 1920 20 houses were erected (compared with none in 1919, 2 in 1918, 9 in 1917, and 234 in 1913, the maximum)." Dr. Pole confirms the recommendation of his predecessor, Dr. Francis, as to the great need for a maternity home.

Dr. Pole's report as school medical officer shows that the education committee provide no treatment. Such treatment as is given is provided by the general practitioners of the district in return for monthly payments by the workmen. Table V. shows that 270 out of 318 minor ailments were treated and only 137 out of 261 defects of nose and throat; that 180 visual defects and 702 other defects were apparently left untouched; and that no action whatever seems to have been taken with regard to dental defects. Dr. Pole only took over his duties on Nov. 22nd, 1920, and no doubt hopes to report next year that the arrangements made for treating the defects found by medical inspection have been greatly improved.

SCHOOL MEDICAL INSPECTION.

Warrington.

In his report on School Hygiene in the County Borough of Warrington, for 1919, Dr. G. W. N. Joseph, the medical officer of health and school medical officer, classifies the elementary schools in the borough under four heads: four of them are modern, up-to-date schools; nine Church schools of an older type are fairly satisfactory; in eight schools, also of an older type, certain defects of lighting, heating, ventilation, &c., might be remedied; while three old schools, accommodating 1259 children, are "badly constructed, defective from a sanitary point of view, and should be replaced as soon as possible." Most of the schools need redecorating, and it is hoped that the worst will be dealt with "during the coming year." (The report is not dated.) There are still ten schools heated by close stoves, which are objectionable on several grounds. Measles (860 cases), mumps (1225), scarlet fever (96) and diphtheria (71) were the chief diseases prevalent during the year. The number of children examined at the routine inspections of the code groups was 4237, of whom 1783, or 42·08 per cent., were referred for treatment; in addition, 5873 children were examined as "special cases," either in school, or at the inspection clinics. The most numerous defects found in the systematic inspections were want of cleanliness (360), enlarged tonsils, or adenoids, or both (291), and defective vision (207). There were only five cases of organic heart disease, and only 11 of tuberculosis. With regard to nutrition, only 0·8 per cent. were found to be markedly defective, and a further 3·2 per cent. below normal. Of the 2532 children whose eyesight was tested, only 8·1 per cent. were considered to require treatment, but 12·2 per cent. were passed as having "fair vision, not less than $\frac{6}{12}$, and without eye-strain." Only 10 cases of pulmonary or other forms of tuberculosis were diagnosed among the code-group children examined, but as many as 218 school children are known to be suffering from the disease in one form or another, of whom 159 are attending school. Dr. Joseph remarks that "the need for a special institution for treating and educating many of these cases is fully recognised, and will have to be faced in the near future." At present there is no open-air school, nor are there any open-air class-rooms, though playgrounds and sheds are used in fine weather during the summer. With regard to physical training, there is no "organiser," and no special instructors have been appointed, but many of the male teachers have had special training in the army. It is to be hoped that these requirements in regard to open-air education and physical training may receive early attention.

remaining, though naturally, under such circumstances, it would be better to deal also with the physical side of the question. In the second place, and more important still, the question whether a psychic stimulus may not affect the sympathetic system and the glandular secretions to a much larger extent than is at present believed still requires more investigation. We know that under suitable psychic stimuli the salivary and gastric glands vary their secretions; that the same applies to secretions of the genital organs; that the emotion of fear will delay or prevent menstruation; and recently I have found that an artificially produced emotion of fear under hypnosis will raise the blood pressure and that such pressure will remain raised for a considerable period after all other signs or feelings of fear have disappeared in the patient.

Such facts as these are suggestive on the positive side; on the other side it is difficult to see how on Dr. Golla's theory a physical disturbance of mechanism constitutes the primary factor in all functional diseases when we consider some of the minor and commonplace examples. For instance, what physical disturbance can be suggested that should cause a woman to have a fear, amounting to horror, of birds when that same woman is not even afraid of rats or mice? Numerous other examples of minor phobias and minor obsessions might be given and I see no reason to doubt a similar cause for these as for major cases. On this side also one must not be dogmatic, and one should be prepared to examine the facts whether they are obtained in the laboratory or by psycho-analytic investigation. One cannot, however, too strongly emphasise the necessity of avoiding premature conclusions that psychical phenomena must have physical causes, and vice versa.

I am, Sir, yours faithfully,

PAUL BOUSFIELD,

Physician to the London Neurological Clinic.

August 21st, 1921.

Medical News.

UNIVERSITY OF MANCHESTER.—The Manchester Education Committee has awarded to Mr. Joseph Parness and Miss Muriel M. Edwards University Scholarships in the Faculty of Medicine of the value of £60 per annum for five years.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL. The Goldsmid Entrance Exhibitions of 112 guineas each have been awarded to A. E. Blake Pritchard, King's College, Cambridge; and N. L. White, St. John's College, Cambridge.

University College Hospital: Annual Dinner.—The annual dinner of Old Students of University College Hospital will be held at the Imperial Restaurant, Regent-street, London, on Thursday, Oct. 6th, at 7.30 P.M. The chair will be taken by Dr. Henry D. Waugh. The secretaries are Dr. A. M. H. Gray and Mr. Gwynne Williams.

"OUR DAY."—An appeal is being made by the Joint Council of the Order of St. John and the British Red Cross Society for flag-sellers on "Our Day," which this year will be on Oct. 1st. Ladies willing to sell flags are asked to send their names to 19, Berkeley-street, W. 1, as soon as possible, indicating the district which they prefer.

THE NEW HARWICH-ZEEBRUGGE ROUTE.—The thrice-weekly service opened this month between London and Zeebrugge via Harwich affords a comfortable and expeditious way of reaching the Belgian watering-places and the Flanders battlefield, as well as a starting-point for continental travel. The twin-screw steamship *Roulers* (late *Vienna*) leaves Harwich on Monday, Wednesday, and Saturday about midnight, returning from Zeebrugge on Tuesday, Thursday, and Sunday nights. Travellers can sleep six hours or more in two- or four-berth cabins and breakfast on board at the Belgian end of the journey if not pressed to catch the early train. It is possible by this route to leave Liverpool-street at 8.40 P.M. on Saturday, spend 18 hours in Belgium, visiting Blankenbergh, Ostend, and Bruges, reaching London again at 8 A.M. on Monday morning. No passport is now required by British subjects travelling by these week-end excursions. The only hardship is the stuffiness of the cabins, which apparently the most up-to-date navigation is unable to mitigate.

Sir Charles Bedford has been appointed honorary adviser to the Secretary of State for the Colonies on questions relating to power and industrial alcohol in the colonies and protectorates.

TRAINING FOR DISABLED NURSES.—The Ministry of Labour announces Oct. 31st as the closing date for applications under the training scheme. This scheme allows for the payment of training fees and maintenance allowance in addition to pension for nurses who, by reason of any disablement due to war service, are unable to return to their pre-war occupation. Applications for consideration must reach the Controller, Women's Training Branch, Ministry of Labour, St. Ermin's, Caxton-street, London, S.W. 1, on or before the closing date, except that nurses who may be demobilised after that date may apply within three months of demobilisation, and nurses who on that date are in attendance at a convalescent centre of the Ministry of Pensions, or as in-patients at a hospital of the War Office or Ministry of Pensions, may apply within three months of their discharge.

HEALTH WEEK.—The object of health week, which is to be held from Oct. 9th to 15th, is to focus public attention for one week in the year on matters of health, and to arouse that sense of personal responsibility for health without which all public work must fall far short of its aims. The chairman of the movement is the Lord Mayor of London, the vice-chairman is Prof. H. R. Kenwood, and Prof. A. Bostock Hill is chairman of the executive committee. The celebration of health week was instituted in 1912, and in 1914, at the request of a meeting of local authorities, the Royal Sanitary Institute appointed a committee to undertake the central organisation; but local celebrations in each centre are controlled by local committees. The programme is left in the hands of the local committees, which may take up a general health campaign or may attempt to concentrate public attention on some particular problem. Questions of a controversial nature are avoided, and stress is laid not on disease processes, but on the benefit to be derived from regard to the laws of health, and the saving of life and comparative immunity from disease which result from an efficient health administration and personal regard for health. Further information may be obtained from the Secretary, Mr. E. White Wallis, 90, Buckingham Palace-road, London, S.W.

DONATIONS AND BEQUESTS.—Mr. Sydney Webb, pharmaceutical chemist, Macclesfield, left £6578, and bequeathed £1000 to St. Dunstan's Hostel for the Blind, £300 to Macclesfield General Infirmary, and £200 to the Benevolent Fund of the Pharmaceutical Society of Great Britain.—The late Mr. Alfred Pointon, J.P., of Birmingham, has left by will £1250 to the Children's Hospital, Birmingham, to endow a bed in memory of his daughter; £2500 to the General Hospital, Birmingham; and £2500 to Queen's Hospital, Birmingham, for similar purposes; £1750 each to the Women's Hospital, Birmingham; the Orthopædic and Spinal Hospital, Birmingham; the Blind Institution, Birmingham; Eye Hospital, Birmingham; Ear and Throat Hospital, and the Skin and Urinary Hospital, Birmingham; £2000 to Middlemore's Homes, Birmingham; £1750 to the Deaf and Dumb Institution, Birmingham; £2000 to the Birmingham and District Crippled Children's Union; £1000 to Dr. Stephenson's National Children's Home; and £500 to the Birmingham Dispensary.—Mr. William Sutcliffe, a Manchester merchant, bequeathed over £12,000 for Manchester institutions, including amongst others £1000 to each of the following: Royal Infirmary, Salford Royal Hospital, Ancoats Hospital, and St. Mary's Hospitals for Women and Children; £500 to each of the following: St. Dunstan's Hospital for the Blind, Heywood Blind Aid Society, Northern Counties Hospital for Incurables; £300 each to Northern Hospital for Women and Children, Manchester Victoria Memorial Jewish Hospital; £250 to Manchester Children's Hospital; £200 each to Manchester and Salford Hospital for Skin Diseases, Royal Albert Asylum, Lancaster, National Library for the Blind, Christie Hospital (Cancer Home), Royal Schools for Deaf and Dumb; £100 each to St. John's Hospital for the Ear, the Ear Hospital, Adult Deaf and Dumb Institution. The board of management of St. Mary's Hospitals, Manchester, has received £1152 from the Hospital Sunday Fund.—The board of management of the Royal Infirmary, Manchester, acknowledges the endowment of two cots by the "A" and "D" Divisions of the City Police Force; the endowment in each case is provided by an annual subscription of 50 guineas.

WHOOPING-COUGH EPIDEMIC AT ST. KILDA.—Dr. Shearer, who visited St. Kilda on August 23rd to inquire into an outbreak of whooping-cough reported by wireless on August 19th, has forwarded his report to the Scottish Board of Health. He found that cases of whooping-cough had been occurring on the island from the end of

Greenwich, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London during July from these principal infectious diseases was 14 per cent. above the average in the corresponding period of the five preceding years. The deaths from influenza in London during July numbered 15, against 149, 77, and 30 in the three preceding months; these deaths were less than a tenth of the average in the corresponding period of the five preceding years.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments have been made:—Surg. Comdrs.—C. V. Griffiths to the *Delhi*, as Senior Medical Officer and Squadron Medical Officer; and G. O. M. Dickenson to the *Victory*, addl., for Haslar Hospital. Surg. Lieut.-Comdrs.—F. J. D. Twigg to the *Pembroke* for R.N. Hospital, Chatham; and M. S. Moore to the *President*, addl., for Cambridge Naval School. Surg. Lieut.—T. Madill to the *Cornflower*. Surg. Comdrs. T. R. Shaw to the *Vivid* for R.N. Barracks (temp.); L. O. Rowan-Robinson to the *Blake*; E. T. Burton to the *Malabar*, addl., for H.M. Dockyard, Bermuda; and T. W. Myles to the *New Zealand* (temp.); P. F. Alderson to R.N. Hospital, Plymouth, for general duties and as Medical Transport Officer, Devonport; and C. R. Rickard to the *Lowestoft* as Senior Medical Officer and Fleet Medical Officer. Surg.-Lieut. J. W. Tighe to the *Espiegle*.

Surg. Lieut-Comdr. F. C. Alton and Surg. Lieut. A. G. Bee placed on Emergency List.

ROYAL ARMY MEDICAL CORPS.

Maj. J. S. Dunne relinquishes the acting rank of Lt.-Col.

W. L. Cowardin (Surg. Lieut.-Comdr., R.N., ret.) to be temp. Maj.

Temp. Capt. W. M. M. Jackson to be temp. Maj. whilst specially employed as D.A.D. of Hygiene.

Temp. Maj. N. H. Oliver relinquishes his commn. and retains the rank of Maj.

Capt. G. T. Baker resigns his commn.

Temp. Capt. E. E. Chipp relinquishes the acting rank of Maj.

Temp. Hon. Capt. D. E. Carter relinquishes his commn. and retains the hon. rank of Capt.

S. H. Woods, late temp. Capt., to be temp. Capt. whilst employed as a Dental Surg.

The undermentioned Capts. to be temp. Majs. whilst specially employed as D.A.D.'s of Hygiene: H. S. Milne and R. W. Galloway.

Capt. H. Bedingfield retires, receiving a gratuity, and is granted the rank of Maj.

The undermentioned temp. Capts. relinquish their commns. and retain the rank of Capt.: C. B. Dyson, S. H. Scott, and R. B. Jenkins.

Maj. E. McK. Williams, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

ARMY DENTAL CORPS.

Temp. Capt. J. Duguid, Dental Surg., from Gen. List, to be Capt.

Temp. Capt. P. P. Hogan, Dental Surg., from Spec. List, to be Lieut., with the temp. rank of Capt., but without the pay or allowances of that rank.

Flight-Lieut. J. Wren, from R.A.F., Dental Branch, to be Lieut.

SPECIAL RESERVE OF OFFICERS.

Capt. T. Patterson relinquishes his commn. and retains the rank of Capt.

TERRITORIAL FORCE.

Lt.-Col. H. G. Smeeth having attained the age limit is retired and retains the rank of Lt.-Col. with permission to wear the prescribed uniform.

Capt. (Bt. Maj.) J. L. Joyce resigns his commn. and retains his rank.

Capt. A. W. Clarke resigns his commn. and retains the rank of Capt.

Maj. E. L. Gowlland to be Lt.-Col., and to command the 4th London Field Ambulance.

Capt. H. D. Davis to be Maj.

Capt. A. H. D. Smith (late R.A.M.C.) to be Capt.

Capt. F. A. E. Crew to be Maj., and command the Med. unit of the Edinburgh Univ. O.T.C.

Capt. S. S. Greaves vacates the appt. of D.A.D.M.S., W. Rid. Div.

Capts. C. G. Meade and W. Goldie resign their commns. and retain the rank of Capt.

Lieut. L. R. G. de Glanville to be Capt.

3rd Southern Gen. Hosp.—Capt. W. B. Secretan resigns his commn. and retains the rank of Capt.

TERRITORIAL FORCE RESERVE.

Lt.-Col. E. B. Dowsett from Gen. List, R.A.M.C., T.F., to be Col.

Maj. C. H. Welch, from R.A.M.C. (T.F.), to be Maj.

Capt. H. Foxton from R.A.M.C., T.F., to be Maj.

Capt. C. M. Smith from 1st Lond. (C. of L.) San. Co. to be Capt.

INDIA AND THE INDIAN MEDICAL SERVICE.

Lt.-Cols. G. H. Bowle-Evans and F. Wall to be Cols.

Bt.-Col. (now Col.) W. H. Ogilvie to be acting Col. while holding the appt. of A.D.M.S., 7th Ind. Bn., Mesopotamia and Egyptian Expeditionary Forces.

Maj. W. W. Jeudwine to be acting Lieut-Col. while commanding the Lucknow Casualty Clearing Station in France.

Temp. Capt. H. R. Shahane to be acting Lieut.-Col. while commanding a Combined Field Amb.

The King has approved the retirement of Lieut.-Col. de V. Condon, in consequence of ill-health.

Major J. McCoy, civil surgeon, Darrang, has been granted a year's leave. The services of Major P. S. Mills have been placed temporarily at the disposal of the Government of Bihar and Orissa. Dr. A. L. Mackenzie, of the Women's Medical Service, has taken over charge of the Bettiah Raj Dufferin Hospital. Major R. D. Saigol, ophthalmic surgeon, General Hospital, Rangoon, has been appointed temporarily to act as Lecturer in Materia Medica in the Burma Government Medical School. Capts. H. S. Anand and K. C. Dube have been appointed Deputy Sanitary Commissioners in the United Provinces. Lt.-Col. R. M. Carter, C.B., of Mesopotamian fame, has proceeded on leave, and during his absence an Indian graduate acts as Professor of Pathology and Morbid Anatomy and Curator of the Pathological Museum, and Major B. Higham as Dean, Grant Medical College, Bombay. Major Anderson, Agency Surgeon, has proceeded on leave. Major J. A. S. Phillips is transferred permanently and Capt. H. S. Anand temporarily to the Sanitary Department of the United Provinces. Lt.-Col. J. B. Christian acts as Surgeon Superintendent, St. George's Hospital, Bombay, vice Lt.-Col. A. Street who has proceeded on leave. Hon. Lt.-Col. R. Row, O.B.E., acts as First Physician and Professor of Medicine and Therapeutics, Grant Medical College, Bombay. Major M. J. Holgate has been appointed to Jail Department, Madras. Major J. H. Horne has been posted to Bombay Bacteriological Laboratory. Major C. H. Barber, civil surgeon, Alagarh, has proceeded on eight months' leave. Major A. Cameron, O.B.E., special malaria officer, United Provinces, has been appointed Civil Surgeon, Allahabad, in addition to his other duties. Lt.-Col. H. A. F. Knapton has been granted an extension of furlough, and on return acts as Surgeon Superintendent, St. George's Hospital, Bombay; and furlough has been granted to Lt.-Col. S. C. Evans. Major Crookshank has been appointed Assistant Director, The King's Institute, Guindy, Madras. Capt. Rowntree, Assistant Director-General, has proceeded on nine months' leave, and Capt. E. S. Goss officiates for him. Major Williams has been appointed to act as Deputy Director-General of the Indian Medical Service. Major J. A. S. Phillips has been confirmed in the appointment of Special Malaria Officer, United Provinces of Agra and Oudh.

DEATHS IN THE SERVICES.

Colonel William Henry Bull, A.M.S. (T.), who died on August 14th at Oswald's House, Stony Stratford, at the age of 69, had been a medical student at St. George's Hospital and qualified in 1874 with the M.R.C.S. Eng. He obtained the L.R.C.P. Lond. in the following year and the F.R.C.S. Edin. in 1882. An enthusiastic volunteer he was particularly interested in ambulance work. During the war he was chief organiser for the Midlands in connexion with the Medical Staff Corps and was responsible for the administration of the Birmingham District Voluntary Aid Detachment. He had been county director of Bucks and was formerly Commissioner of Medical Services under the Ministry of National Service and the Ministry of Pensions. Colonel Bull was a justice of the peace, deputy lieutenant for the County of Bucks, and Knight of Grace of the Order of St. John of Jerusalem, and an hon. surgeon to the King.

The Croix de Guerre has been conferred by the President of the Czecho-Slovak Republic upon Surg. Comdr. C. J. E. Cock, R.N., in recognition of services during the war. The King has given unrestricted permission to the officer concerned to wear the decoration.

Literary Intelligence.—Messrs. W. Heffer and Sons, Ltd., Cambridge, have in the press a volume entitled "The Autonomic Nervous System," Part I., by Prof. J. N. Langley, F.R.S.

Sheffield, East End Branch of the Children's Hospital.—Female H.S. £150.
Sheffield Royal Hospital.—Cas. O. Asst. Cas. O. Each £150.
Sheffield Royal Infirmary.—Asst. Cas. O. £150.
Stamford, Rutland, and General Infirmary.—H.S. £250.
Sunderland, Durham County and Sunderland Eye Infirmary.—H.S. £100.
Sunderland Royal Infirmary.—H.S. £200.
Taunton, Taunton and Somerset Hospital.—Female Res. Jun. H.S. £150.
Western Ophthalmic Hospital, Marylebone-road, N.W.—Non-res. H.S. £150.
West London Hospital, Hammersmith-road, W.—Two H.S.'s. H.P. Each £100. Surgeon.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Somercotes and at Dunkeld, in the county of Perth.

Births, Marriages, and Deaths.

BIRTHS.

CLARK.—On August 17th, at Bayfield, Kent-road, Southsea, the wife of Dr. A. Erskine Clark, of a daughter.

COVELL.—On August 20th, in Constantinople, the wife (Oona Macleod) of Captain Gordon Covell, M.B., B.S.Lond., I.M.S., of a son.

DUNN.—On August 20th, to Rosamond, wife of G. Hunter Dunn, B.Ch., M.R.C.S., L.R.C.P.Lond., Red House, South Farnborough—a daughter.

HOLT.—On August 16th, at Heightside, Burnley, the wife of Lieut.-Colonel T. Holt, R.A.M.C. (T.F.), of a son.

MANFIELD.—On August 21st, at Cairo, Egypt, the wife of A. H. Manfield, M.R.C.S., L.R.C.P.Lond., of a son.

QUIRKE.—On August 22nd, at Brook House, Ullenhall, Warwickshire, the wife of Major M. J. Quirke, M.B., Ch.B. Birm., I.M.S. (retired), of a son.

REIDY.—On August 22nd, at 314, Commercial-road, E., the wife of J. Reidy, J.P., M.D., of a son.

REVELL.—On August 18th, at 4, Matlock-road, Norwich, the wife of Rowan W. Revell, M.D.Lond., D.P.H., of a daughter.

SCOTT.—On August 24th, at Rose Villa, Jesmond, Newcastle-on-Tyne, to Elsie, wife of J. McAlpine Scott, M.D.Glasg., Pensions Hospital, Shotley Bridge—a daughter.

TERRY.—On August 20th, at Barton-street, Gloucester, the wife of H. Cairns Terry, M.B., Ch.B.Birm., of a son.

MARRIAGES.

WARRINGTON—SAMUELS.—On July 22nd, at St. Michael's Church, Colombo, Thomas Warrington, M.R.C.S., L.R.C.P. Lond., to Dorothy Samuels, daughter of G. Young, Esq., J.P., of Culdaff, and widow of Captain A. P. Samuels, Royal Irish Rifles.

YEOMAN—YEOMAN.—On August 24th, at the Presbyterian Church, Neston, Lieut.-Colonel J. B. Yeoman, M.D., F.R.C.S.Edin., D.P.H., Barrister-at-Law of the Middle Temple, to Ida Isabel, widow of Dr. C. W. Yeoman, and younger daughter of the late Mr. James Fergusson, of Liverpool and Heswall, Cheshire.

DEATHS.

BROWNE.—On August 23rd, at Homewood, Hartford, Cheshire, Robert J. Browne, L.R.C.S. & P.I., L.M., late of the Beach, Hartford, aged 67 years.

DUNN.—On August 22nd, Rosamond, dearly-loved and loving wife of Dr. G. Hunter Dunn, Red House, South Farnborough.

NICOLL.—On August 15th, at Woodside-place, Glasgow, James Henderson Nicoll, M.B., C.M., F.R.F.P.S. Glasg., aged 57 years.

SHACKLETON.—On August 8th, on the voyage from Jamaica, of cerebral hæmorrhage, Thomas Francis Shackleton, M.R.C.S., L.S.A.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

DEVELOPMENT OF MEDICAL SCIENCE IN VIENNA.

BY DR. MAX NEUBURGER,

PROFESSOR OF HISTORY OF MEDICINE AT THE UNIVERSITY OF VIENNA

THE reputation of Vienna as a focus of medical art and medical science reaches far back into the past. Such a reputation could be attained only by the harmonious combination of especially favourable factors—the innate national talent deeply rooted in the ethnological medley of Austria, and self-contained tradition, based on the experience of many generations, yet very susceptible to valuable ideas from abroad and to practical progress on foreign lines. Such cultural predisposition made sure of great development of young men transplanted from other countries. The history of the development of the Viennese school also shows that periods of eminence have always been coupled with liberal reforms in education, in conformity with the spirit of the times, in all branches of sanitary science. Lastly, the unhindered activity of highly gifted and energetic men assisted largely in maintaining the rank of Vienna in the scientific world.

The Vienna University was founded in 1365; ever since the days of humanism there had been certain excellent individual teachers of medicine and anatomy, great lecturers on the science of materia medica or the observation of the sick, but the raising of the entire standard was hindered by narrowness of mental development, opposition to the greater freedom prevalent abroad, the conservatism of the medical caste, a university constitution bound to antiquated routine, and want of the necessary institutes and buildings. Only when the State began to recognise its educational duties was a new epoch opened up.

The Work of Gerard van Swieten.

Gerard van Swieten, physician to the Empress Marie Theresa, who was summoned to Vienna from Holland in 1745, effected a signal work of reform and laid the foundations for the institution of a brilliant school. Provided with almost unlimited authority and energetically combating all opposition, van Swieten improved medical science and liberated university teaching from caste prejudice. He had a botanical garden and a chemical laboratory laid out, arranged the purchase of anatomical preparations, increased the facilities for performing dissections, and took steps to develop the almost totally neglected branches of surgery, obstretrics, and ophthalmology. By increasing both the number and the salaries of professors, by appointing eminent foreign scholars to such positions, and by systematically training a number of capable disciples from among native doctors and students, van Swieten succeeded, in hardly more than two decades, in attaining his object. Leyden, the school at which he himself had graduated, served as his model. The most important achievement, however, whereby this great organiser became the true founder of the Vienna medical school, was the institution of a permanent clinic, after the Leyden pattern, which under the management of Sylvius and Boerhaave came to be held in very great esteem. This small clinic in the "Bürgerspital," containing only six beds for men and six for women, was the first established on German soil, and it became the cradle of the world-wide renown of Austrian medicine.

Anton de Haen.

The first professor of this clinic, Anton de Haen, a former fellow-student of van Swieten's, invited from The Hague in 1754, gained by his medical writings high esteem for his school in the learned circles of Europe, whilst his clinical lectures attracted disciples from far and near. Like van Swieten, he stood for Hippocratism, and opposed the rash adaptation of theories and speculations in pathology. During the 22 years of his professional activity he successfully installed that sober system in which confidence is placed only in observations actually made at the sick bed. He encouraged his students to make diagnoses for themselves, and used post-mortem dissection for purposes of instruction and research. Much of the progress made in the recognition and treatment of illnesses is owing to de Haen, who introduced into the clinic, among other things, the systematic taking of temperatures with the thermometer. Of the disciples of this master, Störck, subsequently imperial physician, was the first to investigate methodically the effect of medicaments in experiments on himself, on animals, and by observation of patients.

Correspondence.

"Audi alteram partem."

ANÆSTHESIA WITH NITROUS OXIDE AND OXYGEN UNDER PRESSURE.

To the Editor of THE LANCET.

SIR,—An article with this title, published in your issue of August 13th (p. 326), is of peculiar interest to me, in that so long ago as June 28th of last year Dr. Otto Leyton attended the house committee of the London Hospital, Whitechapel, E., and explained a new method of giving anæsthetics under increased air pressure. He reported that a special theatre should be built, in which this increased air pressure, amounting to an atmosphere and a half, could be provided. He was questioned closely by the committee as to the effect of such conditions upon the surgeons, anæsthetists, dressers, and nurses working in the theatre. He finally reported that he hoped to be able to collect the total funds necessary for the building and equipment of such a theatre.

The question was referred by the committee to the Medical Council for their consideration and report. For the moment, the scheme was held up on account of financial difficulties which had overtaken all hospitals, but we still have hopes of installing this theatre, not only for the administration of anæsthetics on diabetic patients, in whom Dr. Leyton is particularly interested, but for any patient requiring long anæsthesia under nitrous oxide and oxygen.

I am, Sir, yours faithfully,

E. W. MORRIS,
House Governor, London Hospital.

Whitechapel, E., August 24th, 1921.

THE SUPPOSED EXTERNAL EFFECTS OF HUMAN VISION.

To the Editor of THE LANCET.

SIR,—As Dr. C. Russ has apparently taken some offence[1] at the audacity of my criticism, perhaps you will allow me to express my regret that his feelings should have been hurt, and to assure him that, far from intending disrespect, I consider that he himself is under-estimating the importance of his discovery, and consequently the scepticism it justifies. I cheerfully admit that I have no academic qualifications in physics (owing to economic circumstances he also deplores), and that far from verifying his experiments as they deserve I was guilty of typing my criticism immediately upon perusal of his paper. I was not, however, aware that there was any other sanction for comment than interest and relevancy; the publication of a paper in THE LANCET invites discussion by mere practitioners, independent of technical degrees, provided they be well-informed.

My letter was justified by the further information it elicited from Dr. Russ—namely, that the new force is reflected like light and is active in (some) inverse ratio to distance, fundamental facts that Dr. Russ had omitted from his paper. Further, I did not criticise any of his observations or experiments but, accepting his findings, drew certain obvious inferences from his work with a view to verificatory experiment. In particular I tried to show that it followed from his position that the force must be emanating from the macula only or chiefly; that it must be refracted like light; and that within the eye it must be of the greatest intensity since only a minute proportion can reach the objective. I further suggested crucial and inexpensive experiments—an artificial ametropia by interposition of lenses, even cycloplegia—to decide the refraction of the radiant force, and the employment of a patient suffering from a central scotoma (inactive fovea) to verify its macular origin, this suggestion being made to me by an eminent ophthalmologist.

These deductions, though theoretical, are vital to further induction. They point to a force emanating from the fovea, of great intensity and behaving as regards propagation (reflection, refraction, conduction, &c.) in the same way as light. Alternatively, so onerous an hypothesis throws doubt upon the data, especially in view of the complexity and delicacy of the experiments. My scepticism was aroused solely by these considerations, and by the fact that the optical significance of fixation had apparently been overlooked by Dr. Russ and the "leaders of science" he has consulted. This single oversight, following naturally from the methodological error of entering upon a research "in order to give my theory the support of some experimental evidence," leads inevitably to the artificial limitation he places upon his research, the treatment (from preconception) of vision as an un-analysable thing and the exclusion of the eye from consideration and experiment. His problem, even as he stated it, was the detection and demonstration of an obscure and doubtful concomitant of eye-functioning; yet he allowed, so far as can be judged from his paper, his attention to be wholly occupied by apparatus, to the neglect of the properties of this complex organ—the real object for his study. This is all that I meant by "experiment outrunning reflection," and though he errs in the fashion and in good company, neither titles nor seniority nor argumenta ad hominem can force me to recognise such thinking as anything but playing at science.

Finally, I did not introduce psychology—which is not a "force" though it may be "little-known"—to explain the phenomena. Dr. Russ made a psychological phenomenon his starting-point ("the fact that the direct gaze or vision of one person soon becomes intolerable to another person suggested to me, &c."). I merely gave to this psychological fact its psychological interpretation; he, by his own account, forced upon this a physical interpretation and entered upon his research for the purpose of substantiating this.

I must apologise for troubling Dr. Russ with questions that may have been answered at the Congress of Ophthalmologists; but, like many other readers of THE LANCET, I was not there, and like them would be glad to have the matter cleared up, as I for one am not yet wholly an unbeliever.

I am, Sir, yours faithfully,

Glasgow, August 15th, 1921. IAN D. SUTTIE.

THE OBJECTIVE STUDY OF NEUROSIS.

To the Editor of THE LANCET.

SIR,—In your leading article on Dr. F. L. Golla's Croonian lectures you emphasise the fact that the value of his researches into the physical side of functional nervous diseases resides less in his conclusions tentatively advanced than in the orientation they exhibit towards a sorely neglected side of practical medicine. You further make it clear that alterations in neuro-glandular mechanism, muscle tone, &c., do not necessarily afford proof that there is no psychogenic derivation in hysteria and other psychoneuroses and neuroses.

It is, however, essential that those working in this physiological field should not of necessity deduce that such physical changes are the cause of functional diseases, even should they find such changes in every instance. In pursuing research in the real scientific manner, that is, by attempting to find a truth, we must beware of attempting to prove theories which accord with our own beliefs and desires.

Hence in this particular field of work one must remember not merely that physical disabilities may exist independently of psychic disabilities in the same patient, but, and much more important, that two other explanations present themselves, each having a considerable amount of evidence in its favour.

In the first place, a physical disability may act as a stimulus to a psychic complex and produce a psychic reaction which may be cleared up by psychotherapeutic treatment in spite of the physical stimulus in 1840. Skoda was the first to ascertain the physical causes of the origin of the qualities of sound by acoustic experiments and by the study of anatomical conditions; he taught how anatomical alterations, and even the various stages of their development, could be recognised by percussion and auscultation. His "Treatise on Percussion and Auscultation," which appeared in 1839, is a milestone in the history of medicine. Rokitansky's demonstrations and lectures and Skoda's classes for physical diagnosis soon surrounded the two masters with a throng of disciples and adherents who published valuable works in the spirit of their instructors. The second Vienna school was now already an imposing power in the world of science. Amongst the foreigners who came to it for knowledge to last them a whole life-time were men who later themselves became pioneers of science, such as Traube, Kussmaul, or Wilde. The "Gesellschaft der Aerzte" in Vienna, founded in 1838, facilitated the profitable exchange of ideas; in the words of Schönlein, its history was intimately associated with that of medicine in general.

---

[1] THE LANCET, August 13th, p. 362.

A reform of medical teaching, an up-to-date development of the hospitals and institutes, a reorganisation of university conditions in the way of autonomy for academical authorities, and free choice in teaching and learning were realised during the period from 1848 to 1850. The Conference of German Naturalists and Physicians in Vienna (1856) and the celebration of the 500th anniversary of the university (1865) showed the Vienna medical school at its zenith, containing at one time such names as those of Rokitansky, Skoda, Hyrtl, Brücke, Oppolzer, Hebra, and Arlt.

New specialties of medical science were rapidly developed—laryngology and rhinoscopy by Ludwig Türck, and Johann Czermak; otology by Adam Politzer, whose system of the introduction of air was soon known everywhere under his name; neurology and psychiatry by Türck, and later by Meynert; syphilology by Zeissl and Sigmund; obstetrics and gynæcology by C. Braun, and hydro- and electro-therapeutics by Winternitz and Benedikt respectively. It says much for the sagacity of Rokitansky that he should soon have recognised how much morbid anatomy requires to be supplemented by other branches of science, especially by medical chemistry and experimental pathology. Besides other theoretical professorships (for histology, embryology, and medical chemistry), a chair of "general and experimental pathology" was founded in the 'seventies. The first man to be appointed to it was Stricker, a pioneer not only in research but also in the organisation of instruction with the help of the electric lantern, the microscope, episcope, &c.

It is also worthy of mention that the "Josephinum" in the last stage of its existence numbered some very great teachers among its staff; of these we need only name the pathological anatomist Engel and the two physiologists Carl Ludwig and E. Hering. Several of the professors entered the staff of the medical faculty upon the dissolution of the Josephinum.

The Allgemeine Poliklinik: Theodor Billroth, Bamberger, and Nothnagel.

The circle of academical teachers had considerably increased in the course of decades. Since they could not always find an opportunity to teach in the General Hospital, or the other hospitals, a number of them united in the year 1871 to found a consulting institute called the "Allgemeine Poliklinik," which was also destined to serve purposes of instruction, particularly in certain special branches. The Poliklinik, subsequently enlarged by a small hospital and housed in a building of its own, very soon attracted students and graduates from far and near, and always included in its list of teachers names of the best repute.

When death, old age, or sickness had removed the founders of the second Vienna school and their most intimate co-workers from the stage of scientific life, it was not always possible to find the qualified men for the necessary renovation of the staff of teachers, nor yet to gain new laurels for the school. This was, however, achieved by the appointment of Billroth in 1867. This genius, sufficient in himself alone to gain a university world-wide renown, initiated an illustrious era in surgery. A master of operative technique and a surgical thinker of the highest rank, he was particularly successful in developing the department of intestinal surgery, and founded in Vienna a school of surgery of a very special character and extraordinary importance. His scholars became the ornaments of several universities, and in some of them his doctrines are still active at the present day.

In Oppolzer's successor, Bamberger, internal medicine acquired in 1872 a master of the first order by whom the old Vienna traditions, intensified by means of microscopy and chemistry, were carried on. We are indebted to his endeavours for the appointment, in 1882, of Nothnagel, who proved especially capable of forming a connexion between the German school (of Berlin) and that of Vienna, and who left lasting traces of his long activity. The fact that he was not only an excellent pathological anatomist and experimental investigator, but also devoted much attention to the effect of medicines, gave a clinical therapeutical character to his works, while his intense interest in neurology gave his teaching a general value by which the whole school subsequently profited.

Meynert and Others.

Soon after Bamberger, the number of ordinary professors of the Vienna medical faculty was augmented by the ingenious craniologist, Meynert, the excellent representative of forensic medicine Eduard Hofmann, who left at his death an incomparably fine and extensive museum of medico-forensic preparations, and Hebra's most eminent disciple, the great dermatologist, Kaposi. In the 'eighties we have the appointments of the surgeon G. Albert, of the oculists Eduard Jäger and Ernst Fuchs, of the anatomist E. Zuckerkandl, and of the psychiatrist Krafft-Ebing, who was especially active in promoting forensic psycho-pathology and the doctrines of hypnotism. From 1887 onwards, Max Gruber opened up a new era of hygiene. In 1890 von Schrötter, a master of laryngology, was allotted the newly erected third clinic for internal medicine, handing over the control of the laryngological clinic to his colleague Störk.

Predominance of Virchow and the Berlin School.

There is no denying that at the close of the 'sixties the sceptre of German medicine passed from Vienna to the Berlin school, which, under the guidance of Virchow, was progressing from one triumph to another; the disciples of Rokitansky and Skoda paid too little attention to what had meanwhile been achieved abroad, and continued too long in the old groove, showing great interest solely in morbid anatomy and physical diagnosis. Great innovations like antiseptics and bacteriology were taken up too late by the Viennese sceptics, the introduction was retarded of all those equipments which modern research work and modern sanitary measures require. Nevertheless, medicine in Austria succeeded in the course of the 'nineties in catching up that of Germany, and thenceforth contrived to keep pace with it.

Modern Progress and Conditions.

In this connexion, moreover, one should not forget, when comparing the past with the future, that the age of a universal medical centre, in the sense in which Vienna was formerly a centre, is probably past and gone for ever. Methods of scientific medicine have now become uniform everywhere, and new achievements are rapidly made known from place to place; but Vienna retains one of the leading schools of medicine, of which the achievements during the last 30 years will in the future be recognised as forming a large part of the total medical progress of that period. Great progress has been made at Vienna in the more delicate anatomy, especially that of the central nervous system, in the physiology of the organs of sense, in experimental pharmacology, in physico-chemical biology, in the science of serums, and the doctrines of internal secretions. There is hardly a chapter of internal medicine or pediatrics, of dermatology or syphilology, of neurology or psychology, that has not been enriched from the point of view of diagnosis or therapeutics at one of the Vienna clinics or infirmaries. A number of methods of investigation such as, for example, hæmodynamics, endoscopy, cystoscopy, œsophagoscopy, and rectoscopy, were founded or first practised here. The cutaneous reactions of tuberculin were discovered in Vienna, and electro-cardio-diagnosis is best represented here. A mass of diagnostic and operative technical progress in surgery, gynæcology, ophthalmology (which profited so much by cocaine, first employed in Vienna), and laryngology is connected with the Viennese school, which was also one of the first to raise urology, orthopædic gymnastics, and dentistry to a high scientific level. Rontgen's diagnostics found their chief centre in Vienna. The different forms of physical therapeutics, especially light therapeutics and radium treatment, as well as dietetics, enjoy particular attention here.

Conclusion.

The necessary extension and alteration of the old premises for research and instruction by new institutes, laboratories, and infirmaries, has been widely undertaken, and much has been done within the last two or three decades on the part of the authorities and in the way of private charity by the foundation of nursing homes, charitable establishments, and ambulance refuges. All services auxiliary to medical science have been placed at the service of the public, and war has been energetically waged against tuberculosis, syphilis, alcoholism, occupational diseases, infant mortality, and the decreasing birth-rate. The recent war and the events that followed upon it, the financial calamities of the State, have seriously impeded any great development for the time being, but the soil of medical Vienna is ancient and fertile and cannot be condemned to lie fallow so long as the spirits of humanity and scientific research endure.

July. In all but one of the 17 inhabited houses whooping-cough was present, the exception being that of Nurse Mackenzie, who had only returned to the island the night preceding his visit. Whilst cases were to be seen in different stages of the disease, from the late catarrhal to the late paroxysmal, no one at the time of his visit was seriously ill and in no case was there any complication. Dr. Shearer notes that there was a similar epidemic on the island 20 years ago. In the present epidemic no person over the age of 20 has developed whooping-cough, but of the 40 inhabitants under that age all but four have contracted it. These four are the nurse's two boys and a little girl, all of whom have just returned from a holiday on the mainland, and a young woman of 27 years, who had whooping-cough when on the mainland several years ago. Dr. Shearer suggests that this incidence would appear to be strong proof of the rarity of second attacks.

SALFORD MILK-SUPPLY.—In the annual report of the borough analyst of Salford (Mr. G. D. Elsdon) for last year it is shown that notwithstanding a fairly large number of adulterated milk samples taken during the year there was only one prosecution. This apparent leniency is explained by Mr. Elsdon as follows: "It is considered that the primary object of this department is to procure a pure milk-supply, and that legal proceedings should only be taken in cases of apparent fraud or where persuasion fails to cause an improvement. For this cause a somewhat new departure has taken place during 1920. A much larger proportion of the milk dealers have been personally interviewed, whilst in cases where farm samples have been unsatisfactory the farms have been visited with the object of finding the cause and, if possible, removing it." The farmers and dairymen have cordially accepted and acted on the suggestions made to them, and have shown their willingness to remedy the shortcomings. When the samples indicate a defective composition of the milk, new samples are taken by what is called an "appeal to the cow," and if the samples thus obtained show a deficiency in fats the farmer is advised as to improvement in feeding his cattle, with the result that frequently there is found an improvement in the quality of the milk. As a result of this novel method of procedure it is stated that "the milk-supply has been permanently improved, and the farmer or dairyman is left with a comfortable feeling that we are not trying to catch him on some technical point, but doing our best for the general public to get the pure milk-supply to which they are entitled."

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the Committee held on August 9th, a sum of £266 was voted to the 17 applicants. The following is a summary of some of the cases relieved:—

Widow, aged 49, of M.R.C.S. Eng. who practised in Hampshire and died in 1921. Owing to continued ill-health applicant's late husband was unable to make provision for his family, and they are now dependent upon the earnings of the son and elder daughter. Unfortunately, the daughter is now out of employment, and applicant and her three children are dependent on the son's money of £1 7*s.* 6*d.* per week. Voted £10.

Widow, aged 55, of M.B. Dub. who practised in Australia and died in 1919. Since husband's death applicant has had to earn her living as a domestic servant, as she was only able to buy herself an annuity bringing her an income of £60 a year. Owing to ill-health she has had to give up service. Her sister allows her 2*s.* 4*d.* a week. Rent £1 a week. Voted £18 in 12 instalments.

Widow, aged 42, of M.R.C.S. Eng. who practised in London and died in 1910. Applicant was left unprovided for, and after the death of her husband went to live with her mother until the latter's death in 1917; since then she has lived with her widowed sister, and they let unfurnished rooms for which they receive 25*s.* per week. Applicant receives £35 per annum from property left by a sister-in-law, also £10 from friends, and £6 10*s.* by acting as a companion for three months. Voted £15 in three instalments.

Daughter, aged 73, of M.R.C.S. Eng. who practised at Tunbridge Wells and died in 1847. Applicant is partially blind and consequently unable to work. Her sole income is derived as follows: £25 from investments, £20 from the Royal United Kingdom Beneficent Association. Rent and rates amount to £28 per annum. Voted £18 in 12 instalments.

Widow, aged 69, of M.D. St. And. who practised in Dover and died in 1911. Applicant has a boarding-house on the East Coast, but owing to heavy expenses and high cost of living she has not made any profit. Apart from letting her only income is £16 per annum from investments. The remainder of her investments she realised to pay the part purchase of the house, and she has to pay interest on a mortgage of £350. Voted £18 in 12 instalments.

Widow, aged 59, of M.R.C.S. who practised in Hampshire and died in 1913. Owing to enforced sale of house to pay off heavy mortgage, applicant has no means and has lived the last few months by selling her jewellery. She pays 15*s.* per week for board and lodging. This case has been referred to the Fund by the Portsmouth C.O.S. Voted £5.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters J. Symonds, C.B., F.R.C.S., 11, Chandos-street, Cavendish-square, London, W. 1.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, Sept. 5th.—2 P.M., Dr. S. Pinchin: Medical Out-patients. Mr. Bishop Harman: Eye Department. 2.30 P.M., Mr. Simmonds: Visit to Surgical Wards.

TUESDAY.—2 P.M., Dr. Burrell: Medical Out-patients. Mr. Banks Davis: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Mr. Addison: Visit to Surgical Wards.

WEDNESDAY.—10 A.M., Mr. MacDonald: Genito-Urinary Department. 2 P.M., Mr. Addison: Operations. Mr. Gibb: Eye Department. Mr. D. Armour: Visit to Surgical Wards.

THURSDAY.—2 P.M., Mr. MacDonald: Surgical Out-patients. Mr. Simmonds: Orthopædic Department. Mr. D. Armour: Operations.

FRIDAY.—10 A.M., Mr. D. Buxton: Dental Department. 2 P.M., Mr. Simmonds: Surgical Out-patients. 2.30 P.M., Dr. Pritchard: Visit to Medical Wards.

SATURDAY.—10 A.M., Dr. Burnford: Visit to Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients.

Daily:—10 A.M., Visit of Post-Graduates to Wards. 2 P.M. In-patient, Out-patient Clinics and Operations.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Wednesday morning of each week, such information for gratuitous publication.*

BRUNTON, G. L., M.D.Edin., has been appointed Medical Superintendent of Nottingham City Asylum.

CALTHROP, LIONEL, C. E., M.B.Durh., M.R.C.S., L.R.C.P., Honorary Physician to the Royal Bath Hospital, Harrogate.

CLULOW, FLORENCE RUTH, M.B., B.S., M.R.C.S., L.R.C.P.Lond., House Surgeon at the King Edward VII. Hospital, Windsor.

MACMAHON, A. D., M.D., B.Ch.N.U.I., Assistant Medical Officer of Health for Wigan.

MITCHELL, A. PHILP, M.D., Ch.M., F.R.C.S.Edin., Surgeon-in-charge of Orthopædic Department, Ministry of Pensions Hospital, Craigleith, Edinburgh.

SHARPE, H., M.R.C.S., L.R.C.P.Lond., Medical Superintendent of King George's Sanatorium for Sailors, Bramshott, Hants (a branch of the Seamen's Hospital Society).

Certifying Surgeon under the Factory and Workshop Acts: KNIGHT, J. I. F., M.R.C.S., L.R.C.P.Lond., for the District of Tisbury, Wilts.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Jun. M.O. £500.

Ayr County Hospital.—Res. H.S. £120.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.S. £100.

St. George's Hospital, S.W.—Cas. O. £200.

Salford Royal Hospital.—Cas. H.S. £150.

but loans for apprenticeship, tools, and so forth are greatly appreciated, and patients are most honourable in discharging their debts to the hospital. Numerous patients who are assisted in this way do not come under any category for which State aid is forthcoming, a fact which is perhaps not sufficiently realised by potential contributors.

The Samaritan Fund rented beds at various institutions as usual; during the year 1082 patients were sent away, 174 went to "free beds," the remaining 908 costing £2551 2*s.* 1*d.* There is still a great need for more homes for boys from 12 to 18 years, and it is still very difficult to find satisfactory boarding-out centres for the children. Surgical instruments were supplied to 307 in-patients and to 1794 out-patients at a total cost of £2528 5*s.* 8*d.*; of which sum patients' payments totalled £1515 16*s.* 11*d.*, to which the Samaritan Fund contributed £202 0*s.* 7*d.* There was an increased demand for ambulances and cars; the L.C.C. Ambulance Service is now free for the use of St. Thomas's patients. Much work is done in linking up patients in difficulties with the right sources of help and proper agencies. The report contains detailed accounts of the work of the speech clinic and of the tuberculosis, ophthalmic, maternity, venereal diseases, and physical exercise departments.

THE ÆTIOLOGY OF TYPHUS.

ON the headstone of a grave in Harrow-on-the-Hill Churchyard, at the east end of the tomb on which Byron was accustomed to recline, is the following inscription: "William Felkin Lambert. 4th son of Charles Lambert Eqr. of Fitzroy Sqr. London, who died on the 21st of November, 1825, from typhus fever brought on from sitting in School in damp clothes after [pla]ying at football."

SOCIETY FOR CONSTRUCTIVE BIRTH CONTROL.

THE objects of this Society, the full name of which is the Society for Birth Control and Racial Progress, as stated in the preliminary announcement, are (*a*) to bring home to all the fundamental nature of the reforms involved in conscious and constructive control of conception and the illumination of sex life as a basis of racial progress; (*b*) to consider the individual, national, international, racial, political, economic, scientific, spiritual and other aspects of the theme, for which purpose meetings will be held, publications issued, research committees, commissions of inquiry, and other activities will be organised from time to time as circumstances require and facilities offer; (*c*) to offer to all who still need it the full knowledge of the methods of control. We gave last week the names of medical men and women associated with the work of the Society.

WAR DISABLEMENT PENSIONS.

THE Ministry of Pensions calls the attention of officers, nurses, and men, and widows and dependents of deceased officers and men, who served in the war, to the provisions of Sections 5 and 6 of the War Pensions Act, 1921. In accordance with Section 5, any new claim to pension, grant, gratuity, or allowance in respect to disablement must be made within seven years after the date on which the claimant was discharged, or within seven years after the official date of the termination of the war (August 31st, 1921), whichever date is the earlier. No new claims will be considered after the expiry of the prescribed period. A person is deemed to have been discharged from the service at the time when his active service terminated. Under Section 6 any claimant who desires to appeal against the rejection of a claim to pension must do so within a period of 12 months after the date of the notification by the Ministry, to the claimant, of the rejection of the claim, or after the date of the commencement of the Act (August 19th, 1921), whichever is the later date.

SANITATION IN FLANDERS.

SOME of the more observant visitors to the Belgian battlefield and the pleasant resorts adjacent thereto have been distressed at the absence of sanitary conveniences and the apparently low standard of public hygiene in the disposal of excreta. The question naturally arises whether there is any greater prevalence of excreta-borne disease in West Flanders than in adjacent countries where the hygienic conscience is keener. Trustworthy statistics relating to West Flanders which, it should be remembered, suffered more severely than any other Belgian province during the war, are, however, not available, as the rates based on the estimated population are probably too low. The recorded death-rate from all causes in 1919 was 14 per 1000 of the population. The statistics of notified infectious diseases show an average of about five cases of typhoid or paratyphoid in West Flanders during each ten-day period of the present year. Between August 1st and 10th the notifications were 10 typhoid, 14 diphtheria, 10 scarlet fever. Between June 21st and 30th they were 12 typhoid, 14 diphtheria; and scarlet fever was epidemic. Two cases of epidemic dysentery were notified in the first week of July.

DANGEROUS DRUGS ACT, 1920.

THE regulations made under this Act came into force on Sept. 1st. No person may now have in his possession any morphine, cocaine, or heroin, or any preparations containing at least 0·2 per cent. (one part in 500) of morphine or 0·1 per cent (one part in 1000) of heroin or cocaine, or any medicinal opium, unless he is licensed by the Home Office, or is otherwise authorised by the regulations or by the Home Office, or unless it is supplied on a prescription given in accordance with the conditions specified in the regulations. A few preparations (including Dover's powder and gall and opium ointment) are exempted from the operation of the regulations, copies of which can be obtained from His Majesty's Stationery Office. The existing restrictions in regard to raw opium which have been in force under the Defence of the Realm Act remain, with modifications.

The *Chemist and Druggist* has brought out at the price of 1*s.* a useful wall-card summarising the regulations of the Act. The front contains in addition notes on the various special authorisations and tables showing the limits of safety dilution for salts of alkaloids. On the back are tables giving the proportion of dangerous drugs in various official and unofficial preparations. Finally, simple prescription calculations are added. The card is intended for the use of chemists, but would be equally useful to any dispensing doctor.

WINTER RESORT FOR CHRONIC RHEUMATISM.

To the Editor of THE LANCET.

SIR,—May I ask any of your readers who have experience of Mediterranean or other winter health resorts to advise me as to which places are likely to answer to the following requirements:—(1) Dry, sunny, bracing climate; (2) up-to-date facilities for treatment of chronic rheumatic affections; (3) en pension terms not exceeding £1 per day at quieter hotels; (4) lowest possible duties on imported cigars; (5) a reasonable amount of life and amusement.

Owing to residence in the East, I am unfamiliar with the essential points of difference between the winter resorts of Europe. I am, Sir, yours faithfully,

I.M.S.

August 25th, 1921.

FOREIGN POSTAGE RATE.

THE Postmaster-General complains of the number of insufficiently stamped letters sent to places abroad. These letters are duly forwarded, but are charged on delivery with double the amount of the deficiency, the surcharge being retained by the foreign post office. The prepaid rate of postage on letters from the United Kingdom to British possessions generally, the United States, Tangier, and H.M. ships and troops on foreign stations is 2*d.* for the first ounce and 1½*d.* for each succeeding ounce or fraction thereof. For all other places abroad the rate is 3*d.* for the first ounce and 1½*d.* for each succeeding ounce.

ORTHOGRAPHY IN UGANDA.

THE names in the clinical note on Human Anthrax in Buganda Kingdom, by Dr. W. L. Peacock and Dr. H. Lyndhurst Duke (THE LANCET, August 13th, p. 332) are not misprinted, as some correspondents have hastily assumed. The formation of the words Buganda, Muganda, Luganda, &c., is according to the Bantu language there spoken. The prefixes *Bu*, *Mu*, and *Ba* signify respectively the country, one of its inhabitants, and more than one inhabitant—i.e., the plural form. *Luganda* signifies the language. *Uganda* is the Swahili form, and *Buganda* the Luganda form, of the name of the country. In Luganda the use of prefixes modifies the meaning of substantives in the manner shown as follows: *embuzi*, goat; *gubuzi*, a huge goat; *kibuzi*, a fair-sized goat; *kabuzi*, a little goat; *wambuzi*, Mr. Goat, and so on.

THE AIRMAN'S PHYSIQUE.

THE aeronaut is exposed to various perils. In a recent issue of the *Military Surgeon* Major W. F. Bonner ascribes 2 per cent. of losses of American airmen in the war to enemy action, 8 per cent. to mechanical defects of plane or engine, 90 per cent. to the failure of the pilot himself, which should prove the great responsibility of the flight surgeon, who decides whether a pilot is fit to fly, and a series of tests to help in determining this question is given. In the same journal Lieutenant J. F. Neuberger, senior medical officer at the naval air station on Rockaway Beach, is of opinion that to pilot an aeroplane is a strenuous physical exertion, and that no airman should be accepted for it if under 5 ft. 7½ in., or with less weight than 10 st. 10 lb. His index of measurement is $P + p - T$, where P is the weight in kilogrammes, p is the chest measure in centimetres, and T is the height, also in centimetres. For the good average flier the figure is −20, but the less the result the better. Light weight is of no advantage to an airman. He is the brain of this delicate, valuable mechanism, and the brain should be, must be, sound. Also he must have great staying power.

Leopold Auenbrugger and Maximilian Stoll.

In the earliest years of de Haen's activity, one of the most important methods of diagnosis—percussion—was discovered by the Viennese doctor, Leopold Auenbrugger, and published in 1761 in a small but most momentous treatise called "Inventum novum." This achievement was not appreciated as it deserved to be until some 50 years later; and then, at first, only abroad. Subsequently, however, Auenbrugger, who had merely been active as a simple practitioner, became a recognised master in Vienna.

Temporarily, though not in an adequate measure, percussion came to be employed at the Vienna clinic before the end of the eighteenth century—i.e., at the time when de Haen's immediate successor, Maximilian Stoll, presided there. This eminent teacher and scholar, who devoted special attention to epidemiology, was recognised in all contemporary reports as the most celebrated clinical teacher then living. His activity was principally associated with the movements towards reform during the reign of the Emperor Joseph II., of which important results still survive.

Medicine under Joseph II.

The most successful of these was the foundation of the "Allgemeines Krankenhaus" (General Hospital), which still exists in commemoration of charity, bearing above its chief portal the words: "Saluti et solatio aegrorum." This famous hospital was opened in 1784; although its prime object was a centralisation of humanitarian institutes, the "Allgemeines Krankenhaus" also served from the very first for purposes of research and instruction through the incorporation of the clinic which was transplanted thither.

A less successful creation was the medical and surgical academy and institute, the "Josephinum," of which the chief object was the training of efficient army doctors, the institute possessing the right of conferring the doctorship of surgery. The institute, founded at the instigation of the imperial surgeon Brambilla, was housed in a very imposing edifice and came into possession of the necessary educational auxiliaries, such as a valuable library and precious scientific collections, the latter including the anatomical preparations in wax fashioned under the supervision of Fontana at Florence. The "Josephinum," opened in 1785, never thrived properly, was forced to close its doors twice on account of reorganisation, and was completely given up in 1873. Although it did not quite fulfil the purpose for which it had been intended, especially in regard to scientific research, it considerably promoted the secondary objects of its founder—i.e., the development of surgery, and the gaining of a better social standing for those that practised it.

The Emperor Joseph, untiring in work for the welfare of the people, knew the shortcomings of the science of medicine, and tried hard to remedy them. He encouraged young men of industry and talent to specialise, and furnished them with means for journeys abroad to this end. The most thorough of the young doctors thus favoured was Johann Boer, who took control of the obstetrical infirmary in 1789, and opened up a new epoch in this branch. Ophthalmology, too, began to develop conspicuously in Vienna, principally represented by Barth, who distinguished himself as a daring operator for cataract and as a master of the technique of injections. Among his scholars Ehrenritter shone as an anatomist, Georg Prochaska as a histologist and physiologist (reflex action, &c.), and Josef Beer as an oculist.

Johann Frank.

The chief representative of the Viennese school, however, at the end of the eighteenth century and the beginning of the nineteenth, was Johann Peter Frank, the founder of public hygiene as an independent science, a brilliant organiser of medical matters, and a gifted clinical professor. The early activity of Frank, whose "Manual of Internal Medicine" was a standard work for decades, had gained him a reputation which reached far beyond the confines of Germany. He united with abundant learning and medical capacity an unusual gift of administration; director of the Allgemeine Krankenhaus and head of the medical clinic from 1795 onwards, he left evidences of creative enterprise which are not yet obliterated. To him the clinic, now enlarged to 21 beds, was indebted for an organisation which has become a pattern. Many contrivances still maintained —e.g., the formal record of the patients' history according to a definite plan; the daily noting of their condition; their alimentation according to four dietary schemes, &c.—had their origin in his time. From the great stock of invalids in the hospital, Frank selected cases suitable for instruction; access to the clinic, and service therein, was exactly regulated; the visitors were divided into spectators and practitioners, the latter having patients who were allotted to them for treatment under supervision and upon whom they had to report to the professor. He also made chemistry and morbid anatomy clinically useful, and founded a pathological anatomical museum, to the control of which Vetter, an eminent assistant professor of anatomy, was appointed. This untiring scholar succeeded in a short time in forming by his own effort a valuable collection of 400 preparations.

The period of Frank's activity comprises many interesting medical events, chief among them being the introduction and official institution of vaccination, for which Ferro and de Carro had spread a lively propaganda from 1799 onwards. Vienna was the first town on the Continent to which Jenner's process found access. Besides the arguments for and against vaccination, the sensational debut of Gall with his theories of the skull agitated medical and non-medical circles at the close of the eighteenth and the beginning of the nineteenth century. It is well known that Gall—like Mesmer, the apostle of animal magnetism some decades earlier—was obliged to quit Vienna to find a more favourable soil for his doctrines abroad.

The First Half of the Nineteenth Century.

With the departure of Frank from his infirmary in 1804, the splendour of the older (first) Vienna school began to fade. After Frank's immediate successor Valentin von Hildenbrand, the author of the best book on typhus in those days (1810), internal medicine had no important official representative in Vienna until almost the middle of the nineteenth century. The political reaction, especially pronounced after the Vienna Congress, was reflected in the fate of the medical faculty, so long, that is to say, as the latter stood under the control of Andreas von Stifft, the omnipotent physician to the Emperor Francis. It was the golden age of bureaucratic decrees in sanitary and educational matters rather than of scientific progress, but again single brilliant representatives of special branches were not lacking. This may be said in the first place of obstetrics, which found a reformer in Boer; and of ophthalmology, two of the teachers of which, Josef Beer and Friedrich Jäger, attracted students from the whole world. Appreciative mention should also be made of the surgeon Kern, who greatly simplified the process of healing wounds; of Bernt, representing forensic medical science, and subsequently of the anatomist Berres, an early representative of microscopical research. A professorship for forensic medicine was founded in 1805, a surgical operating institute in 1807, a clinical ward for ophthalmology in 1812, an ordinary professorship for ophthalmology in 1818—institutions which gave the medical faculty of Vienna a considerable advantage over others.

The autobiographies or memoirs of several celebrated German and foreign doctors tell of youthful impressions gleaned from the scientific and anatomical collections, the infirmaries and hospital wards, in Vienna. The most interesting document of this kind is certainly Wunderlich's little book called "Vienna and Paris," published in 1841. In this work, by the Leipsic professor who was later to become so famous, the Paris school, with all its merits, is described as predominating during the first four decades of the nineteenth century, and then attention is drawn to the almost unnoticed rise of a new school in Vienna, and prophetic allusions are made to the future. After a long stagnation the time had come—so Wunderlich wrote—when "something was again to be learnt in Vienna, and things to be seen there that elsewhere would be sought in vain."

The "Second School" of Vienna.

A characteristic of the new, the so-called "second" school of Vienna was the reconstruction of all medical knowledge on exact foundations. Starting from the achievements of the French, the school of Vienna effected a complete breach with the half-speculative, half-empirical past of medical science, and a rejuvenation of German medicine. The necessary mass of material was found in the Vienna General Hospital, and suitable men appeared to undertake the work entailed.

Rokitansky and Skoda.

The men in question were two young Vienna doctors, Rokitansky and Skoda, both from Bohemia, associated in spirit as they were united in friendship, with common aims and of almost equal age. Rokitansky, who became assistant professor of anatomy at the General Hospital, and curator of the institute of pathological anatomy in 1832 and extraordinary professor two years later, sought to ascertain the causal connexion between certain types of anatomical changes and certain clinical symptoms, and by a whole series of post-mortem examinations to gain an insight into the causes and gradual development of the phenomena of disease. His famous manual, published in the years 1842–46, and almost unparalleled in the literature of the profession in the richness of its contents, completely established the anatomical idea in medicine and made pathological anatomy the basis of the science of healing.

Parallel with Rokitansky's research was the work of Skoda, who served as assistant doctor at the General Hospital from 1833 to 1839, after which he was appointed to the independent control of a section for consumptive patients adaptation or leads to final damage. But the well-nigh incredible demands made upon the machinery of man's body in and behind the battle-line, in all situations upon the land or under the earth, high in the upper air, in the sea or within its depths, by no means make up the tale. Our forces were engaged in every climate, from the Equator to the Arctic regions, and were faced by innumerable local or accidental variations of diet. Here again were required the applications of physiological studies of heat loss and of heat production to manifold practical problems of clothing and of diet. What would have seemed a fanciful fairy tale barely twenty years ago might in particular be told of the miracles wrought by the studied application of our knowledge of vitamins in diet, in saving from painful disease or death many thousands of men in diverse climates and fields of war.

LESSONS FOR CIVIL LIFE.

At home the bodies of the civilian population were exposed to many stresses, often hardly less than those of active service. Men and women alike were exposed to arduous toil, to dangerous occupation, to poisons of many kinds needed for munitions, and in all these dangers the guidance of the physiologist was needed for the avoidance of industrial fatigue and loss of output and for devising protection against industrial poisoning. The whole nation was threatened by the menace of starvation, and our escape from that, itself one of the governing conditions of our ultimate victory, was due to a system of rationing and of the management of food materials, animal and vegetable, which was based on accurate physiological knowledge, won by experimental methods.

I touch on these points here briefly and in outline only in order to draw attention to the special influence which, as I think, the war has exercised upon the position of physiology in this country. The physiologists gave no exceptional help to the nation during the war; the exponents of every branch of science were needed, were ready, and were used, in our national crisis. Hardly one division of science can be named the deficiency of which would not have made defeat inevitable. It is a truism and a commonplace to say that no bravery and no fortitude could have avoided defeat without the help of scientific men and of the fruits of experimental science, though that commonplace has not, I think, ever yet been enshrined in the addresses or thanks of Parliament or in the prayers and thanksgivings of our churches. But we may recognise, perhaps, that the nation as a whole, and those especially who have the government, public or private, of large groups of men in their hands, have learned that obedience to physiological law is a first necessity for the maintenance of the body machinery in health and for its effective and harmonious use. They have come to know, moreover, that the men who alone can guide them to this obedience are those who have learned in the school of investigation from nature herself. The nation has seen a minister fall whose control of the people's food was not based upon physiological law, and his successor gain renown whose adoption of the teaching of physiological experiment was early and faithful. Nor was this by any means an isolated object-lesson. There is no doubt, surely, that physiologists have a new vista before them of immense public usefulness, if they will hold themselves in readiness to give the same kind of service to the country in the stress of her industrial life during peace as they gave so freely and to such effect in time of war.

LESSONS FOR THE PHYSIOLOGIST.

But if the war brought these lessons to the general public, what lessons have come from it to the physiologist himself? I would only recall briefly here the considerations which were brought home with sufficient clearness to us all, I think, during and after the closing stages of the struggle. The war, in the first place, displayed before us new and gigantic fields of physiological study. Viewing these so far as we can, even at this distance, dispassionately, we see how the stresses and accidents of warfare in all their variety offered to our study a series of experiments made upon the human body, and on a gigantic scale. Only by disciplined study of the results at all stages of these trials of war in all their varying degrees of horror and distress could effective aid be given in palliation of suffering or its avoidance. It was inevitable that study of this kind and upon so great a scale should result—as, happily, it did result—in much permanent gain to physiological knowledge and to the beneficent power that all sound knowledge brings. New insight was given into the functional patterns of the nervous system and into the orderly hierarchies, so to speak, under which this or that function is brought into subordination to another of superior rank, and new knowledge was gained of the phenomena of separation and repair in the outlying nerve trunks. Accurate information was collected of the nutritional needs, quantitative or qualitative, of human beings under varying conditions; and, in particular, many special conditions of warfare brought to the test, established the fundamental usefulness, and stimulated the growth of that newest chapter in physiology already mentioned—that dealing with the elusive but potent accessory factors in nutrition—the vitamins. These examples must suffice where scores of others familiar to all of you might be given.

In the second place, the experience of the war has had wholesome effect from its tendency to remove the barriers that here and there had grown up between physiologists and the practical needs of medicine. Physiologists had valued, and justly valued, their academic freedom of inquiry within the universities, and, indeed, we know that practical utility could not be better served in the long run than by the detached pursuit of knowledge for its own sake. But, partly for reasons of hospital and professional organisation already touched upon, and partly because, to its obvious and immense gain, physiology had attracted from other paths men who were not, and had never become, medical men, there were some capital parts of the subject of which the chief explorers had never used the medical field of work or brought to medicine the weapons they had, perhaps unwittingly, at command. We can recognise already that this partial divorce has been changed by the war into a union likely to be increasingly fertile. Of the professorial chairs of medicine or directorships of medical units established since the war, for the advance of medical knowledge within hospitals in accordance with the university standards and ideals acknowledged in other subjects of study, it is remarkable that to the greater number of these there have already been appointed men whose training has been in the methods of the physiological laboratory, and who applied that training to urgent medical problems of the war. There is hardly any one of our schools of physiology, moreover, to which some piece of living experience has not been brought in these last years to enforce the old lesson of the value to science itself of bringing natural knowledge to its fullest utilitarian applications. The practical fruits of scientific labour are found, if our hands are put out to gather them, to contain within themselves, like the natural fruits of the earth, the very seeds from which new knowledge and new fertility will spring. Many of our leaders in physiology brought to the problems of war the accumulated knowledge of their lives, as patriotism and humanity dissolved at a touch the hedges of custom and use. I know of not one such who did not find in the application of his vision and training to the actual problems before him, first, a wholesome reminder of the limits of his knowledge and its clarity, and, second, new clues towards its advance, and that by no means only in a familiar or an expected direction. The stimulus of practical need here, as so often in experience, advanced the growth of knowledge beyond the point of immediate application to practice. Those who studied to find the best and most practical means of saving life threatened by severe hæmorrhage, or by the shock of wounds or operation, found in the course of meeting the immediate emergencies almost endless

UNIVERSITY GRADUATES.

THE preliminary report, just issued, of the Registrar-General gives in convenient form the number of graduates, men and women, of English Universities who were on the Parliamentary electoral register in the spring of the present year:—

University.	Number of electors.		
	Total.	Men.	Women.
Oxford	9,132	8,602	530
Cambridge	10,799	9,061	1,738
London	10,723	8,412	2,311
Combined Constituency	3,394	2,574	820
Durham	571	477	94
Manchester	1,388	1,050	338
Liverpool	536	351	185
Leeds	289	220	69
Sheffield	120	105	15
Birmingham	333	233	100
Bristol	157	138	19
Total	34,048	28,649	5,399

AN INSURANCE BROKER.

IT has come to our notice that an enterprising person, calling himself an "Insurance Broker," is calling upon medical men, and inviting their attention to the merits of life policies issued by various insurance companies, adding as an inducement to a medical man to take out the policy that he would be in a position to place a certain number of examinations for life insurance in the doctor's hands. This person then, we are informed, proposes to accept the doctor's first premium on some form of policy agreed between himself and his new client. In a certain number of cases medical men appear to have been so foolish as to have believed that a policy for life, accident, motor-car casualties, and so on, could be taken out in that manner, and to have paid premiums which, never having reached the insurance office, resulted in no policies. In one case a doctor does not seem to have been worried even by this; his worry commenced when he tried to draw compensation for a motor accident. Some medical men had enough knowledge of the world to refuse to part with money in that informal manner, and it was through such a medical man that one of the insurance companies in question found out what was happening, for the inquiry that reached them gave away the deception that was being practised. In some cases the policies have been duly put through, in which cases the medical men found themselves insured, though the companies may not have received the first premiums.

We tell the story to warn our readers against an ingenious and insidious deception which may be offered for their acceptance.

TWO NEEDLESS DEATHS.

Two inquests were held in London recently on the same day upon the bodies of persons who themselves must be held to have been responsible for accidents which proved fatal. In the one, a young man travelling with his friends in a train moving at 50 miles an hour, by way of a joke sat upon the ledge of the open window and fell out backwards. His friends managed to hold him by the feet until the train was stopped, and appeared at the inquest to ascribe blame to the railway officials because the train was not pulled up sooner in response to the communication cord. The deceased, however, was found to have sustained injuries to his head which might have occurred immediately after his fall, and the officials pointed out that at whatever moment the bell may have been rung a train moving fast cannot be pulled up suddenly without danger to all its passengers. The jury expressly found that no blame attached to the servants of the company.

In the other case referred to, a woman living in a flat in Marylebone was being taken up in a lift worked by a girl 15 years of age. When she reached the second floor, where she lived, and before the lift stopped, she herself opened the door on the landing, there being apparently no door to the lift, and began to step out. The lift was then about a foot below the landing, and the girl attendant said that the woman slipped and fell, and that she, the girl, pulled the rope to bring the lift level. Precisely what then happened is obscure, but the lift began to descend instead of rising, possibly because a hurried and more or less lateral pull at the cord had as its result the exerting of vertical pressure in the wrong direction. In any case the unfortunate woman, who was struggling to regain her feet, was caught with her head outside the descending lift and killed. In this case a verdict of accidental death was returned, and though the jury did not blame the girl attendant they added a rider to the effect that they considered her too young to have charge of a lift. It is to be pointed out as to this that young boys and girls are in charge of lifts in very many buildings, that where lifts are not in constant use it is hardly a "man's job," and that even a grown person is not always cooler in an emergency than one 15 years of age. Of course, an older person might have interfered to stop the passenger when she opened the door and tried to get out before she reached the landing, but even this is doubtful. The fault must be looked upon as primarily that of the passenger and she paid a terrible price for it.

No precautions can altogether prevent foolish actions by persons who choose to behave rashly. Some railway companies place bars across their carriage windows. This may cause loss of life for which they would be blamed if in the event of an accident persons trapped in an overturned carriage found themselves unable to escape. There are always dangers to be encountered in otherwise safe conveyances, and not only in trains and lifts, if those using them refuse to be guided by prudence and good sense.

THE REVENUE FROM PATENT MEDICINES.

ACCORDING to a return prepared by the Excise authorities the number of licences issued (at 5*s.* each) to makers or vendors of patent medicines in the year 1920 was, in England, 38,332, and in Scotland, 3339—total for Great Britain 41,671—on which the amount of duty collected was £10,421. These figures show an increase as compared with the years 1917–18–19, but are still below those of pre-war years. The licence duty does not extend to Ireland.

The stamp duty on patent medicines before the war varied from 1½*d.* upwards, according to the price charged for the medicine, but from Oct. 20th, 1915, the rates of duty were doubled, the minimum being fixed at 3*d.* The net receipts from this duty by the revenue authorities for the last ten years have been as under:—

Year.	England. £	Scotland. £	Total. £
1911	322,696	2,950	325,646
1912	324,861	2,996	327,857
1913	325,420	2,899	328,319
1914	357,750	2,627	360,377
1915	331,033	2,744	333,777
1916	617,876	9,575	627,451
1917	726,894	6,019	733,913
1918	797,366	6,449	803,815
1919	1,056,435	9,259	1,065,694
1920	1,322,054	10,007	1,332,061

ST. THOMAS'S HOSPITAL SAMARITAN FUND.

THE annual report for 1920 of the Samaritan Fund and the activities of the lady almoner's department of St. Thomas's Hospital has now been issued, showing that the work done has covered much old ground, gradually expanding as needs increased. The Samaritan Fund (founded in the year 1852) provides all necessary adjuncts to hospital treatment, such as convalescence, surgical appliances, temporary allowances, fares, extra nourishment, &c. That its assistance has always been of a varied nature is shown by the fact that in the first year's report one of the items of expenditure was the the redemption of tools. The Fund is, unfortunately, small in comparison to the size of the hospital and the needs of its patients, and this year subscriptions, except in special cases, have been unusually small. By means of careful administration and an immense amount of work the Fund has kept clear of debt, and the needs of no patient have been disregarded, but the outlook is not very encouraging.

Subscriptions are urgently needed, together with convalescent letters and free hospitality for patients who are not actually ill but need rest and fresh air. Considerable care is required lest the help afforded by such a fund should tend to lessen the independence of the patient and, in the end, render the family group weaker and less able to stand alone. Therefore, when help is required, be it convalescence, surgical appliances, or nourishment, the first source considered by the almoner is the patient, his family, and relatives, the Samaritan Fund subsidising their contributions. Naturally, such efforts depend on the state of the labour market and other social and economic considerations. During the earlier part of the year 1920 there was comparatively little unemployment, and patients' contributions towards convalescence and instruments amounted to £2981 3*s.* 2*d.*, partly paid in direct sums, partly by means of loans, faithfully repaid. At the end of the year the outstanding loans only amounted to £38 11*s.*, the whole of which will be gradually repaid, and the bad debts came to the negligible sum of £7 6*s.* 2*d.*, the total cost being £5079 7*s.* 8*d.* Of necessity, the patients often cannot repay other forms of assistance. A temporary allowance is given while the breadwinner is laid up in order to free his mind from anxiety and to keep up the standard of living of the family. The amounts granted are based on the family income,

A Lecture

ON THE

RE-EDUCATION OF THE BLINDED,

WITH SPECIAL REFERENCE TO THE BLINDED SAILOR AND SOLDIER.

Delivered at Moorfields Hospital

By Sir ARNOLD LAWSON, K.B.E.
F.R.C.S. Eng.,
OPHTHALMIC SURGEON AND LECTURER ON OPHTHALMIC SURGERY, MIDDLESEX HOSPITAL, ETC.

The problem of educating a child born blind and that of re-educating one blinded after the usual period of education has passed are two totally different matters. The former, broadly speaking, consists in finding some method by which the lack of one sense can be supplemented by extra training of the remaining senses. Thus a child who is born blind and has never seen a bird can be taught to appreciate the shape and characteristics of birds by the demonstration and handling of stuffed birds and models. All the intellectual faculties can be brought into play by side-route methods. Observation and concentration, the two most important desiderata of education, are developed by exercise of hearing, touch, and memory, whilst the expression of ideas by reading and writing after the blind methods are fairly easily acquired by the blind child of average ability when instructed by specially trained masters and mistresses.

For one who has already been educated on the lines of a sighted child, re-education after blinding is a problem of much greater difficulty, and previous to the recent war attempts to deal with it were incoördinated and unsatisfactory. A young adult blinded by accident or disease might ultimately learn to read Braille with facility—probably he did not. There were several most estimable societies devoted to the relief of such cases, but they, for the most part, worked by money grants and pensions, although others did excellent work in the maintenance of workshops, where the blinded could learn the trades of brush, mat, and basket making. It was not always an easy matter to get a person into these workshops, and if the person did not feel inclined to go there no moral pressure was applied. If the blinded boy or girl preferred to sit by the fire most of the day doing nothing, or to be led about the street playing a penny whistle or chanting some doleful ditty or hymn, or perhaps turning the handle of a piano-organ, there were few to say nay or to make any special effort to turn him or her into a useful member of society.

The rapid influx of men blinded in the war from its very commencement brought the problem of the re-education of the blinded very keenly to the fore. St. Dunstan's Hostel, the biggest work of private enterprise that the world has ever seen, has shown what can be done and how it can and should be done, and it is to the methods of training as exemplified by the work of St. Dunstan's Hostel that I intend specially to direct your attention to-day.

But before discussing methods of re-education let us see what are the special difficulties. In the first place the patients have already been educated through and by means of the eyes. Re-education means in fact commencing all over again on different lines at a period when maturity has been reached and the natural receptiveness and plasticity of the childish intellectual response to training is over. The child who is congenitally blind is much better off than the blinded adult. It cannot miss what it has never experienced, and all its faculties are trained easily enough to supplement what it lacks. In the case of the blinded man, the intellectual senses have been, to a very large extent, dominated by the eyes, and subservient to them. It is true that he has gained a very great deal by the experience won by means of his sight before it was lost; but the losing of it reacts against him in that he can no longer put his experience to the test of the eyes on which he was accustomed to rely. The blind child has never gained this experience of the eyes, but intuitively seeks to gain experience by other methods which come naturally to it, but which are totally unnatural to the sighted child.

DIFFICULTIES OF RE-EDUCATION.

That is the first great difficulty—the having to re-educate on totally new lines—and it becomes of increasing significance according to the patient's age, which is the second difficulty. For as we live and get older each one of us gradually becomes at first fixed in our methods of action and habits of thought, and then gradually less capable of absorbing fresh ideas, and less willing to try to absorb them. Thus we see that the re-education of a blinded person is only possible for a certain period of life. After that time has passed we must be content with an incomplete and increasingly inefficient result from our efforts. As we say at St. Dunstan's, the man is trainable or untrainable, and the former class should theoretically, though, alas, not practically, embrace all cases blinded up to the age of 40. From the age of 40 to about 50 years there may be a certain amount of effective re-education, but the amount gained by the patient is not in proportion to the effort made, and after the age of fifty, with the exception of a few who in the past have been highly intellectual, the re-education resolves itself in most cases to providing the patient with methods by which he may serve to pass the time pleasantly. The learning of Braille is a good instance of this, and it is found practically useless to instruct in this subject when the patient is over 40 years of age, though there are exceptions. The patient may master its technicalities at a much later age than 40, but it is rare to find one, who, commencing after this age, becomes sufficiently conversant with it to read Braille with real facility and with genuine pleasure.

The third difficulty is presented by the patient's individuality, which is a factor of enormous importance. It is very disappointing trying to re-educate a country bumpkin who has successfully resisted efforts to educate him when he had his sight. Such a one has passed the best educational time with his intellectual vision almost entirely subservient to the practical necessities of obtaining sufficient to eat and drink by unskilled labour. Only the simplest forms of re-education are applicable to such a man, although he may have attained manhood but a very short time, and even such simple training as may be applicable to his case may be extremely difficult to instil. On the other hand, a man who has received and proportionately absorbed the benefits of a good education in the past, may, under certain conditions, be capable, after he has been blinded, of resuming his usefulness as a citizen to as great or even greater extent than that to which he attained before blindness overtook him. Of that fact we have had many notable examples in history, and in most recent times the names of Arthur Pearson and Towse will go down to posterity as examples of what a blinded man can achieve. However great these two men were in their sighted life, whatever power of achievement might have been theirs had they retained their sight, the fact remains that their great services to their fellow men followed on their blindness, and that what the world would have called their disablement has proved their glory.

Thus it is seen that the re-education of the blind man must be conducted on individual lines, varying with the person. It is not possible satisfactorily to educate every child, blind or not, on the same individual lines, though it is constantly being attempted and is the one great difficulty of school life, but it is even less possible in re-education because the dominating individual characteristics of a grown man are infinitely more dominating than those of a child, and whereas it is possible to turn a child away from its

EDICAL COLLEGE LIBRARY

Presidential Address

[ABRIDGED]

AIMS AND BOUNDARIES OF PHYSIOLOGY

Delivered on Sept 7th before the Section of Physiology of the British Association for the Advancement of Science

By Sir WALTER M FLETCHER, K B E M D,
D Sc Camb F R C P F R S
PRESIDENT OF THE SECTION AND SECRETARY TO THE MEDICAL RESEARCH COUNCIL

UPON the occasion of our meeting in this metropolitan city of Edinburgh the seat of an ancient university and a great centre of medical study and practice it has occurred to me that it may be profitable for us to consider the part which physiology should rightly take in its relation to national life, to learning and to medicine Not only the place of our meeting indeed but some special circumstances of the present time seem to make it fitting that we should here review the progress, the proper scope and the prospects of our chosen subject We are now just half a century from the time when physiology first came to take its present position in this kingdom as one of the great branches of university learning and as a vital part of medical education We have seen the close of a war which though it diverted and distorted the progress of the science yet brought it great opportunities of service in national life and taught us lessons here as in so many other directions of which we shall do well to take profit The passing of the war moreover has brought a period of change and unrest during which impulses towards reform are being chequered by the results of fatigue or reaction Both here and in America it may be said that while physiology has come from the war with enlarged outlook and responsibilities it is exposed to some new and perhaps dangerous influences in the present time of rapid resettlement It may well be worth while then to look now both forward and back to see the road by which we have hitherto been led and its relations to that which now lies before us

[The lecturer then sketched the rise shaping, and establishment of physiological knowledge during the past 50 years, through which period England led the rest of the continent in experimental results and in new ideas After brief reference to the developments which followed Harvey's discovery, he pointed to University College, London, as the home of modern physiology and to the great Sharpey as its father He showed how Sharpey, in touch with the best progress in France and Germany organised the study of physiology between 1836 and 1874 and he made sympathetic reference to the aid of the Prince Consort who was familiar with continental progress The work of Sharpey in its original home he said had been continued by Starling Bayliss, and their colleagues while from Sharpey's school were derived the sturdy branches of physiological study which have borne fruit at Oxford under Burdon Sanderson Gotch, and Haldane and at Cambridge under Michael Foster Langley Gaskell Hopkins, and Sherrington who has now transferred his services to the sister University In his consideration of the work of all these pioneers Sir Walter Fletcher was able to show that from British experimenters have come the root ideas in nearly all the great primary fields of physiological knowledge He gave as examples the nature of the heart beat modern conceptions of the central nervous system, the analysis of the functions of the sympathetic system and the detailed study of nutrition and respiration Sir Walter Fletcher also pointed out that at no time earlier than the war had the British physiologists either the menial assistance or the other resources which their colleagues abroad had commonly commanded He then proceeded —]

LESSONS OF WAR EXPERIENCE

Before 1914 physiology was being developed as we have seen in its still youthful status as one of the primary departments of knowledge, it had become a subject of independent university rank Large and important parts of this development had proceeded at one or other of the ancient universities out of touch with great centres of population and out of touch therefore with immediate medical needs In some degree this was not without advantage and for two main reasons Detachment from the pressure of need allowed the free pursuit of knowledge for its own sake and a full surrender to the hintings of nature wherever her clues might lead the inquirer Experience amply showed moreover that when physiology was presented among other university subjects for study it gained first as recruits and later as distinguished workers many able young men who were attracted to it often from other subjects by the fascination of its problems and without regard to any of its potential applications to medical or other practical ends These were great gains which it would be easy if it were not unnecessary to illustrate by many convincing examples Yet there were some heavy counterweights on the other side of the balance The practical and urgent needs of humanity as found at the hospitals were not brought with full or due effect to the notice of physiologists Those in charge of hospital patients were not selected to advance or habitually engaged in advancing medical knowledge and new physiological conceptions as they took shape in our laboratories only slowly and partially came to have effect in medical practice and medical study The physiologist to his own certain loss and to the no less certain loss of medicine held aloof from the bedside often when access was possible and remained immersed in his laboratory interests Little pressure indeed was ever brought to bear upon him by the physician to come to his aid Connected with the evils of this separation was the divorce which the accidents of development had set up between physiology and pathology as though the study of the damaged body could be separated from the science of the living organism and of its reactions to disturbance from the normal Yet while the physician had come to tolerate the approach of the pathologist to the bedside it occurred too rarely that he felt the need of the physiologist or made himself familiar with new devices of physiological investigation

If from a hospital in time of peace the most obvious call had seemed in the past to come from the side of infective disease or morbid process for the help of the pathologist in war the stress put upon the healthy human body made the physiologist and his methods indispensable Bacteriological work and studies of immunity had their prominent place of course in the detection and prevention of infective disease and wonderful were many of the achievements seen under this head But in a sense the more complete the prevention of infective disease the more apparent became the physical stresses of war The violences offered in modern warfare to the human body—whether through exertion and exposure by terror or excitement in physical damage by lead or steel or in chemical attacks by poison and not least through the incredible stresses of flying high and fighting in the air—all these brought many new and urgent calls for precise physiological knowledge and for new studies by the physiologist The results of pain and fear of haemorrhage of shock by wound or operation—all these needed further analysis before sound treatment could be devised or improved New studies were needed of changes in blood pressure and blood volume and in the qualities of the blood itself, new inquiries into the finer vessels of blood circulation and their relation to the nervous and other systems and new analyses of the chemical mechanisms of the body and of the modes by which want of oxygen is met by use of knife and fork when he finds out that this is expected of him, and that he is not allowed to be spoon-fed like a baby, a habit that the blind rapidly acquire if left to themselves. Of course a certain amount of aid at meals is essential, such as the removal of bones of fish and so forth, but nothing is worse for the patient, and so contrary to the spirit of independence, than hand-feeding by another person.

Then, again, the patient must regain interest in his personal appearance—the neatness and cleanliness of dress and appearance. Both these qualities have to be guarded by outside aid; the blind, if left to themselves, very speedily become indifferent to these points and slovenly in their habits. Shaving is easily taught and the patient quickly learns also to interest himself in the appearance of his clothes, his finger-nails, and the neatness of his general turn-out, especially when he is one of a community where these points receive attention and excite comment.

USES OF SOCIAL INTERCOURSE.

The social intercourse which is one of the great advantages of a community, will soon react on his attitude to outside affairs. He will begin to be less engrossed by his own misfortunes and to take more interest in what is going on round him. He will come in contact with others more advanced in re-education, whose experiences will prove of interest, whilst the knowledge of their difficulties similar to his own, and overcome, will stir in him the spirit of emulation to succeed himself. The old contemptuous proverb about "the blind helping the blind" is one that should be cut out of the wise sayings, for in very truth we know that the blind can and do help the blind, and that nothing is more helpful to the recently blinded man than the experiences of one who has gone through the mill himself and gained the victory. This was one of the special good works of Captain Towse in the war, and often have I heard of the comfort he brought to the bedsides of those who were sunk to the lowest depths of despair by the loss of all that seemed to make life worth living.

The advantages of social life are further exemplified by the relaxations, distractions, and amusements which are possible in a college for the blind. The greatest importance was attached to this side of re-education at St. Dunstan's, and rightly so. Firstly it is difficult for a blind man, especially if he is young, to obtain the physical exercise necessary to good health, unless he is specially taught; and, further, such exercise not only interests and amuses, but it educates as well; for it teaches the blind that many of the pleasures which seemed lost can be regained, and this knowledge has its moral value in bringing out the spirit of independence and in awakening and stimulating the desire to compete once more in the life of the world around.

PHYSICAL EXERCISES.

St. Dunstan's spared no pains to provide the men with all kinds of relaxation and amusement, and it was marvellously interesting to see how soon and with what keenness the inmates interested themselves. Perhaps the most popular of all the amusements was dancing. This was regularly taught and eagerly learned, and it was wonderful to watch the ability displayed by many of the men who were encouraged to compete for prizes given for grace and skill. Singing was another favourite amusement for those who possessed the necessary vocal ability, whilst, similarly, instrumental music found many adherents, and this progressed to the forming of a band of blind musicians. But besides indoor distractions, outdoor sports were in great request, and none more so than rowing and sculling, which furnished splendid exercise, whilst rowing races were eagerly anticipated and keenly contested. These are but examples of the kind of sport and amusement that all the healthy blind can do and do well. There are others, and perhaps some of them would seem utterly impossible. Thus I know of an excellent golfer who stuck to his game even after he had become completely blind. He found that after practice he could, aided by directions from a good caddie, continue to drive a straight ball and pitch fairly accurately to the green, and when there he would measure the distance from ball to hole and test the green by walking from one to the other, then proceeding to putt guided by the sound made by the caddie striking the tin with an iron club.

INTELLECTUAL AND ECONOMIC ASPECTS OF TRAINING.

Thus it is evident that a short time spent at a place like St. Dunstan's should, and generally does, succeed in revolutionising the outlook of one recently blinded and speedily prepares him for the more serious part of the training. The actual training must be considered from two points of view: (*a*) that designed to cultivate the intellectual qualities of the blinded man, and (*b*) that intended to provide him with a means of livelihood. The first chiefly comprises the learning to read Braille and writing by means of the typewriter. Possibly the optophone will eventually supplement Braille, but at present this instrument does not seriously compete with it. It is too expensive for the ordinary person and its difficulties are very great, even to one who is gifted with a musical ear. Braille, too, is disappointing in a very large number of cases. As an intellectual exercise it is excellent, but to read it with sufficient facility much practice and continued exercise of that practice is necessary. The learning of the very numerous contractions is essential, and, even when mastered, proficiency is only retained by constant exercise to prevent the memory from slipping. Thus those who are blinded at a comparatively late stage of life—i.e., after 40 years of age, can rarely acquire the art, and further, the young blinded man of the labouring class, whose education has been completed at the age of 14 years, and who has thereafter spent life in manual labour, has rarely either the intellectual ability required or the necessary delicacy of touch in fingers hardened and blunted by physical toil. Thus it comes about that whilst it is always desirable to include Braille learning as an essential factor in training, the final results of teaching are often disappointing, the pupil very frequently abandoning it when once set free to start life again in the world. One interesting point about Braille is that it seems to appeal very little to those whom one would imagine, at first hand, had most need for it. I mean that those who are busily employed in intellectual work—work requiring much mental concentration—do not seem to use Braille much. It takes too much thought and the man tired from brain work all day cannot, as a rule, be bothered with it at night as a means of relaxation. Typewriting, on the other hand, has not any serious drawbacks of this kind, and the blinded person of average intellect speedily acquires great proficiency. It is an exercise which seems to appeal to every blinded person, and the desire to become expert is stimulated at St. Dunstan's by the present of a typewriter to each man who succeeds in passing what is a very searching test examination of his powers.

Then as to the training the blinded with a view to earning a livelihood. Before the war workshops in which the blind of the labouring classes were taught mat-, brush-, and basket-making, did a great deal of useful work, not only in teaching trades, but in furnishing a market for the wares. There was also a struggling society to train the blind of a higher social standing in the art of massage, which is eminently suitable for the blind; the useful work of this society was much hampered by want of funds. For the comparatively small number of blinded members of the middle and upper classes there was really nothing open, and the teaching of Braille was practically the only effort made on their behalf. The advent of war stranded a number of blinded officers and educated men, and it became as important to provide a sustaining interest in life and often a means of livelihood for these sufferers as for the more numerous patients of lower social rank. A revision of the whole question promptings to further inquiries, to be followed then or later—inquiries into the physical, chemical, or biological qualities of the blood, into its relations to the vessel walls, and into the functional changes of the capillary blood-system and the factors affecting or controlling them. Those who fixed their attention upon the damage wrought in the respiratory organs by poison gases were led to many new studies of the fundamental physiology of the lungs. The lymphatic system of drainage of the lungs was re-examined, and wide new experimental studies of the modes of regulation of the breathing were undertaken which have thrown new and valuable light upon the normal mechanisms of respiration. An inquiry into the poisonous action of the high-explosive trinitrotoluene, and into the possibility that slightly abnormal forms of this substance, found as a small contamination of the normal form, might be specially toxic, led to a clear negative answer. But it led unexpectedly, it is both curious and useful to note, to the discovery that one of these abnormal forms was an effective reagent in the laboratory. By its means the chemical structure of a constituent of muscle substance known as carnosin was for the first time determined, and carnosin has now been synthesised artificially from simple materials.

In sum, then, we may gratefully recognise that the war in its horror and waste has not brought evil without admixture of good. We may be encouraged at least to hope that the active coöperation which the war established and fostered in diverse ways between the physiologist and the medical or surgical clinician may remain to bring lasting good, on the one side to the cause of learning and its advance, and on the other to medical education and to medical progress.

SYNTHETIC CONCEPTIONS.

[In the third section of his address Sir Walter Fletcher invited his audience to review the aims of physiology and the boundaries to which it should properly extend in its relations to other subjects of study. He said that the analysis of the separate functions of each part of the body showed an inevitable mental process, as the anatomist revealed more and more accurately the visible machinery of the body. But the pursuit of knowledge by particular technical methods had led to specialism, new named sciences growing up within the old. Step by step with progress in analysis there had been continual advance towards synthesis. Of this absorption of analytic data into synthetic conceptions he gave examples, dealing with the discovery of the hormones, recent additions to knowledge of the brain and spinal cord and of the functions of the various systems of fibres and cells involved, the analyses of the biochemist and the discoveries in the modes of regulation of breathing.

He closed this part of his interesting address with the following words of warning:—]

In the rapid growth of medical schools throughout the English-speaking world there are present signs that the essential part which physiology plays in medical education and study may wrongly masquerade as the only service physiology has to give to man, and may appear to fill the measure of her rightful status. In more than one of the great American universities physiology is treated either in theory or in practice as a subject within the Medical Faculty to be housed within the medical school, yet at the same time not as a subject in the Faculty of Arts or of Science, nor to be studied alone or with other sciences as part of a liberal and non-professional education. It is rare in the United States for physiology to be studied by any but professed medical students, and there is some reason to think that it is becoming rarer in Great Britain than it was a few years ago.

To my mind this tendency is to be deplored. It implies a reversal of that growth of physiology in freedom which began half a century ago and from which such good fruit has already been gathered. It has two chief evils among its inevitable results. Removed from its position among other university subjects by geographical separation that in some universities amounts to transportation and exile, it is deprived of the kinship and coöperation of the sciences touching its own boundaries—those of zoology, embryology, and botany, of agriculture, of psychology, of physics and chemistry. Assigned, if not limited, to a place in the medical curriculum, it is apt to be narrowed in its claims and outlook, and to lose not only its proper neighbours, but even parts of itself, whittled away in the organisation of a purely medical programme in the guise of pharmacology, neurology, toxicology, and the like, for which special funds may be available, separate places in the time-table reserved, and independent departments provided. But a second evil strikes more deeply. Any arrangements that give in effect a restriction of physiological studies to medical students alone must be doubly injurious. It is injurious to the general course of education, because it tends to cut away from the other university students the opportunity of possessing themselves, either as a primary or secondary study, of the knowledge and discipline of physiology which has educative value in the highest degree for the cultural or the practical sides of living. And here, secondarily, we may notice the loss to an applied study only less in importance to that of medicine; I mean the science and practice of agriculture. It is injurious, again, to physiology itself, because we know well from reiterated experience how many promising recruits for the future advancement of the subject have been brought to it, often, as it were, by chance, in the course of their university life, attracted to it whether from classical studies or mathematical, or from other branches of natural science. A notable number of the chief leaders in the science of the past and present generation have so been attracted, without any previous thought of medical studies as such, whether these have been added later or not; of these leaders, not a few whose names are well known to us all have never become, in the technical sense, students of medicine at all. They may have lost by this, but should we willingly have lost them?

I hope that what I have earlier said with regard to the great service that physiology has both to give to medicine and to receive from it will acquit me of any charge of desiring less, rather than much more, intimacy and intercourse between them. I believe that no better service can be done for the good of both than to increase their mutual offices and the ties between them. But we must see that, in uniting physiology to medicine, we do not uproot it from that soil in which alone it can abundantly flourish and bear fruit, the environment of a university with all that that connotes. If there be any serious doubt of the reality of the dangers I have indicated, I would point to the dearth of men fitted to promote and teach the subject among those coming from the schools in which physiology is regarded as a medical study and no more, and is not given its full university status. In the United States at present there is a grave and admitted dearth of suitable candidates for chairs of physiology, in spite of the remarkable work which has been done there in recent years and the fine material equipment in general available. I venture to offer my conviction that the prime cause of this shortage is the absence of the great recruiting possibilities of university life and the undue limitation of physiology to medical students. Men coming to physiology as a "preliminary subject" and nothing more are not likely to think of it as their life-work, but will pass through it not to return.

[In conclusion, Sir Walter Fletcher referred briefly to the high intellectual and æsthetic sanctions of physiological study.

U.S.A. GENERAL HOSPITALS AND T.B. PATIENTS.—The United States Public Health Service in a recent bulletin regards the opening of the general hospitals to tuberculous patients proposed at the Boston annual meeting of the American Medical Association as a step in the right direction. This hospitalisation will, it is believed, be largely preventive and in line with the medical tendency of the day to look to prevention instead of to cure.

quickly learn card games, and I have seen more than one good bridge player among the blinded.

The turning out of an expert blind workman must, therefore, be a comparatively long affair. The average stay of a man at St. Dunstan's is about a year; but very many of the wounded took a much longer time than that, and many had to spend long periods of rest at one of the convalescent homes attached to the Hostel.

SPECIAL DIFFICULTIES OF THE BLIND CRAFTSMAN.

When training has been completed the blinded man has to be launched out into the world to earn his living. Very little difficulty has been experienced with regard to those who have been re-educated in special work, such as massage, telephony, &c. These men are able to compete in the world's market on fairly equal terms with the sighted man, especially when there is a substantial pension in the background to help matters along. But in the case of those trained in handicrafts, as most of the St. Dunstan's men have been, the situation is different and bristling with difficulties. The blind handicraftsman cannot possibly compete on equal terms with the sighted. He cannot work so quickly, or continue to do so for such long hours. His work is apt to deteriorate in quality unless periodically supervised. Little mistakes creep into his work and pass unrecognised, so that the occasional fault is apt to become habitual unless there is someone to overlook the work and put matters right again. The purchase of raw material in the best and cheapest market and the disposal of manufactured goods to the best advantage require help. For these reasons the blinded handicraftsman on leaving St. Dunstan's is handed over to the great After-Care Department, which has done and is doing as much for the blinded of the war as the Hostel itself. This department is ably managed by a brilliant young officer, Captain Ian Fraser, who was blinded early in the war and has been specially selected and trained for the work.

AFTER-CARE.

Thinking over the matter, one would naturally say that the most simple way of surmounting the difficulties of the case would be to draft the handicraftsmen into communal workshops dotted over the country at large commercial centres such as London, Liverpool, Manchester, and Birmingham. Without doubt the principle of this arrangement would be ideal, but practically such a course was neither possible nor altogether desirable for blinded soldiers. The expense of starting and maintaining such workshops would have been prodigious. The existing blind workshop accommodation was and still is woefully inadequate for blind civilians, let alone blinded soldiers and sailors, and I believe I am correct in saying that at the present moment room can be found for only about one-third of the blinded civilians. Then, again, supposing the possibility of such workshop accommodation, it is doubtful if the blinded soldier, with his pension of £2 10s. per week, would work in harmony with the blind civilian whose work has specially to be subsidised to give him a living wage. It would not be fair to pay one hand a less wage for a given article than another, and on the one hand the civilian, unless he received special treatment in this respect, would be in a difficult position, and would resent the soldier with his pension being subsidised on equal terms; whilst on the other hand, the soldier in spite of his pension would probably refuse to work when he was paid at a lower scale than others engaged on the same job. Thus, the formation of large workshops for blinded soldiers and sailors being impracticable, it was decided to deal with the matter by settling the men in various localities where they produced their work at home. This arrangement necessitated (*a*) the formation of a large central depot, which is situated in London. and (*b*) the division of the United Kingdom into districts, each under the care of a specially trained and paid inspector. At the central depôt all the business of the After-Care Department is handled. Raw material is bought and stocked, and manufactured goods are stored for disposal. It is also the headquarters for the financial side, and the general reference centre for all correspondence, and all work connected with the welfare of the men. The local inspectors have much to do. Each man, when trained, is settled in his native district or as near as possible to any locality that he may choose, and it is the business of the inspector of his district to see to his being comfortably and suitably housed. Once there, he is visited at least once in every six weeks by his inspector, who supervises his work and points out mistakes if necessary. The inspector is also responsible for the supply of material and for the sending of his goods to be disposed of by the central depot.

The work is not directly subsidised, and quite rightly so, for with his pension the trained man can earn a very good living; but indirectly a very great deal is done to help each man. The material is supplied at actual cost price, and all expense connected with handling and storing material is charged to the department and is a direct financial loss to it. Thus, the more a man works the more he costs the after-care department, and so, indirectly, the man who works most gets most. Then, as regards sale of work, the man is paid by return of post at the highest market rate obtainable at the moment, and no charge is made for the carriage of his goods to London and for the storing of them. Very often the actual disposal of the goods is much delayed by overstocking, and in the meantime the price may depreciate, so that the department again stands to lose, sometimes very considerably.

In times of sickness, accidents, or business difficulties the department is ready to help. Special care is taken that the patient is well looked after, and, if necessary, money grants are made to help in tiding over times of trouble. When convalescent the patient is sent free of all expense to himself to one of four convalescent homes attached to St. Dunstan's. These are situated at Hastings, Brighton, Cheltenham, and North Berwick, and the home is prepared to keep him as long as necessary. These homes are also used to provide annual holidays, and every man is entitled to a fortnight's rest yearly at one or other of them.

Thus it is obvious that the work of the after-care department is very great and very expensive. It is reckoned that each man, when trained, costs the department about £17 per annum. Of this sum about £12 is expended indirectly in subsidising his work, whilst the remaining £5 represents the average cost from possible sickness, accidents, business difficulties, and holidays. At the present moment there are about 1200 handicraftsmen thus settled, costing the department roughly about £20,000 per annum. Unfortunately there remain about another 300 men to settle, so that the department has to face a considerable increase in expenditure for some time to come. It must not be thought that the department only looks after the handicraftsmen. It is ready to provide help for all those in special lines of work when required, and especially is its help needed with regard to sickness and holidays, but, as already pointed out, those in special work often earn very good wages indeed, and for the most part need no help except in cases of emergency.

THE UNTRAINABLE BLIND.

Mention must be made, too, of the great class of untrainable blind, those who on account of age, infirmities, mutilation, or some consecutive disease, such as tabes, cannot be trained to earn an independent livelihood. Men of this class need a modified course of re-education. For some a light occupation, such as brush-making or chopping sticks for firewood, may still be possible, whilst string-bag and netting, for them as for others, may help to pass away many weary hours. The Moon system of reading, which is very much simpler than Braille, may be taught to those who are too old to learn the latter, but the amount of available literature is limited, and reading Moon is a slow business and apt to become very tedious.

natural inclinations, it is generally not so possible in an adult.

The last great difficulty is one which is not constantly present but which may prove a great stumbling block. It is the mental attitude of resistance of some blinded persons towards attempts to re-educate them. I think it exists temporarily in almost every case as a natural sequel to the first losing of the sight. The sudden plunging of the sighted man into darkness by the havoc of a shell-burst or bullet must be, and is, followed by a period of mental depression, often of a most acute character, which persists in many patients for a long period. The shorter this period can be made the happier for the patient, but while it lasts the patient is apt subconsciously to resist any effort to ameliorate his position. The younger the patient the more easily and quickly will he usually react to outside influences to help him, but in the case of people who are blinded in the evening of their lives it is not unusual to find a persistent passive attitude of inability to take interest or to attempt to make the best of circumstances. Of course, when a patient has gradually lost vision by the progress of some insidious disease, the ultimate catastrophe, delayed perhaps for several years, loses the greater part of its horror—the patient has had time to become acclimatised as it were. It is the *sudden* or rapid loss of that upon which the beauty and enjoyment of life seem to hang, which causes the persistent melancholy from which so many old people fail to arouse themselves. Believe me, it is a far better thing to lose the sight in the spring or summertime of youth than in the autumn or winter of life. The natural sympathy of the world is for the blighted prospects of youth; all the might-have-been of life seemingly so utterly destroyed, the future so hopelessly dreary. After all, the elderly or old man has had his time of youth unblasted by blindness—not so many years of life still remain, and though blindness is always hard he cannot win the same intensity of the world's sympathy as the young blinded man. And yet the world is wrong. For one of the great blessings of youth is its inability as a rule to look too far ahead. Foresight is largely a matter of experience won by age, and youth is always ready and usually capable of reclaiming and retying the threads of life which have for a time parted and separated him from most of what makes life lovely and pleasant. An old man generally cannot pick up the threads at all; or if he can find them he cannot tie them correctly—he is confined by his experience and his powers of outlook. He cannot start all over again—it is too late to do so even if he were to try. The old man is in fact, as I have already pointed out, untrainable.

It was this spirit of youth that was the chief asset in the production of that wonderful cheeriness which so pervaded St. Dunstan's during the war, and so astonished all who went there. The society of comrades similarly maimed helped in a very great measure, but neither the society of comrades nor the sympathy and help of all who worked at St. Dunstan's would have brought that laughter and that brightness if St. Dunstan's had been peopled by old men instead of boys, as there they mostly were.

CATEGORIES OF BLINDNESS.

For the purposes of training, a man may be defined as blind when his sight is so bad that he is unable to earn an independent livelihood as a sighted man can do. Thus the blind can be divided into three categories or classes: (*a*) those who have completely lost their sight; (*b*) those who still retain fragments of vision but no useful sight, their powers being limited to bare light perception or to some sense of form or movement over the whole or part of their visual fields; and (*c*) those who still possess some useful sight, vision that enables them to get about without aid and to recognise large objects close at hand, but insufficient to enable them to earn their living as sighted men. This latter class, as we shall see later on, embraces the most difficult cases for training purposes, because it generally happens that a patient cannot be taught to learn without using the weak sight that is still retained and which is thereby very frequently endangered by the instinctive straining set up. Class (*a*) is the most satisfactory of the three, for those who have completely lost their sight most quickly become resigned and most easily are taught to do without it, and indeed fragmentary vision is of positive harm to many in that it gives no real comfort but rather tends to confusion and to increase the difficulties. I have often heard patients say that they were worried by the retention of a little sight in one or two corners of the visual field, and similarly have heard others rejoice when they had lost it. It was well recognised at St. Dunstan's that the completely blind were the easiest to train, and our experience there was that these were the most contented of the patients, and that grumbling and discontent and other little troubles, generally present in any community, seemed chiefly to emanate from those who still retained a little sight.

PRELIMINARY RE-EDUCATION OF THE MORAL SENSE.

Now before re-education in the sense of intellectual or manual instruction can be satisfactorily commenced there must be a re-education of the patient's moral sense. When sight is first lost the patient is plunged into an intellectual abyss from which there seems no way of escape. He finds, or fancies, himself completely dependent on others for everything. He cannot walk, eat, or amuse himself, and his every action seems to necessitate an appeal for help. He may at first try to be independent, but probably soon gives up such apparently futile efforts; he tends more and more to lose his sense of individuality and to rely entirely on the sympathetic help of those about him. The very first step in re-education consists in teaching the patient to recover his lost independence and to regard his difficulties not as disabling, but as inconveniences which can largely be discounted. That is one of the great secrets of the success of St. Dunstan's, for there the patient, removed from the environment of sympathising relatives and friends, only too willing to do all for the sufferer, whilst the sufferer gradually becomes entirely willing that all should be done for him, is brought into the midst of a large community where all are experiencing similar difficulties and learning to overcome them. The association of comrades in blindness, all of whom are there for the same purpose—viz., the overcoming of difficulties, combined with the companionship of teachers who help in the overcoming of them, soon begins to react on the patient, who finds out that all is not lost to him. With that feeling of reaction comes the desire to try to do what he can to help himself, and as soon as that advance is made the progress will be rapid. I think the experience of the last six years has shown conclusively that colleges or communities for the blind are the first essentials in re-education. It is not possible satisfactorily to train the blind by private instruction or by directly depositing them in workshops. Prior to everything else must come the learning of independence.

INITIAL TRAINING AT THE HOSTEL.

The patient having arrived and settled down at the hostel soon finds that while all are ready to help him it will be greatly to his advantage to help himself, and practical aids to do so are the next essential preliminary. Thus to enable him to find his way about the building narrow strips of carpet, the edges of which can be detected by the stick with which each blind man is provided, are laid along rooms and corridors, and handrails, where necessary, afford further help, whilst stairs are indicated by patches of rubber or wood which the feet instantly detect. With these aids the man rapidly acquires confidence in walking alone in places and buildings which he has learnt to know, and will soon progress with almost the same ease and confidence as the sighted man.

Feeding neatly has also to be learnt, and the patient will with some practice attain a proficient time we must not let them have undue weight in our subsequent investigations of the case. We must also admit that they may be fallacious. I could give details of the clinical history of a brain tumour in a boy who, between the ages of 6 and 20, was repeatedly examined by several neurologists. The question of tumour was often discussed, but the verdict was always in favour of a neurosis. At the age of 21 optic neuritis developed and slowly other symptoms appeared, and the diagnosis of an intracranial growth became certain. He lived five or six years longer; an autopsy could not be obtained. In this case the question arises, Had the tumour existed for over 20 years, or did its development begin about the time when optic neuritis was first observed, its presence and the symptoms of neurasthenia having little or no relation to one another?

Do we give adequate consideration to the analysis of subjective symptoms? Do we try to deduce as much as possible from a study of each individual symptom? The study of such a symptom as constant headache is perhaps not likely to reveal features peculiar to any particular disease, but the possibility may be admitted when we recall the characteristics of other pains; for example, the momentary pains of tabes dorsalis, which, as F. Buzzard [2] has recently pointed out, differ from other lightning pains in the fact that they seem to stab the limb at right angles to its surface.

Numbness.

This subjective sensation is a common initial symptom of affections of the nerves, spinal cord, and brain, and may exist for some time before any objective signs of disease can be detected. Its presence should put us on the alert for future developments; for example, temporary numbness of the face or hand may precede by several weeks an attack of hemiplegia, or the onset of the characteristic symptoms of disseminate sclerosis.

In testing for anæsthesia the use of the tuning fork must be remembered, for, as R. T. Williamson has repeatedly stated, loss of the vibratory sensation, all other forms of sensation being normal, is one of the earliest signs of an affection of the sensory tract.

In the Bradshaw lecture,[3] given in the year 1901, I described an interesting case of numbness affecting the outer side of the left arm, which had persisted for four years without the development of other symptoms; I remarked that the distribution of the numbness suggested a slight lesion of the fifth cervical root, possibly the constant action of some poison which had a preference for that region, and that the future development of signs of serious disease could not be excluded. Last year the patient consulted me again—that is, 23 years after the onset of the paræsthesia. The upper limbs, with the exception of the hands, were completely paralysed, and most of the muscles atrophied. The knee-jerks were exaggerated, there was ankle-clonus, with an extensor plantar reflex on both sides. The condition closely resembled amyotrophic lateral sclerosis, but there was slight anæsthesia down the outer sides of both arms, and this, together with the long duration of the case, made me think that the lesion was some rare variety of pachymeningitis with invasion and compression of the spinal cord.

Motor Disability.

Just as there may be paræsthesia without anæsthesia, so there may be motor disability without any paralysis, spasm, or incoördination of muscles. In disseminate sclerosis one of the earliest symptoms noticed by the patient is a feeling of weakness and heaviness in the legs. On examination no motor weakness can be detected or possibly only slight weakness of the flexors of one hip. In the occupation neuroses there is a defect in the coördination of muscles needed for the performance of some skilled acquired movement. In my experience, taking "writer's cramp" as an example, a careful examination has rarely revealed anything beyond the fact that the patient had imperfect control over the muscles used in writing, every other movement, as well as sensation, being perfectly normal. It must always be borne in mind that such disability in the performance of delicate actions may be the first sign of a cerebral growth, of paralysis agitans, or other grave disorder of the nervous system.

Before passing to a consideration of some positive signs of disease let me say a word about the terms "functional" and "organic." These terms are misleading and their abolition is desirable. A symptom, whether subjective or objective, is evidence of a disturbance of function, and nothing more. Anæsthesia or paralysis merely indicates a disturbance of the normal activity of the sensory path in the former case and of the motor path in the latter; an extensor plantar reflex, interference with the normal activity of the pyramidal system. Compression of the ulnar nerve at the elbow is followed by numbness and tingling and some anæsthesia of the two inner fingers; the impaired sensation persists as long as the compression is continued. There must be some tissue change caused by the squeezing. Is the condition to be called functional or organic? In my opinion every so-called functional disorder has an anatomical basis—a molecular or other change, however transitory that may be.

The Plantar Reflex.

The remissions and variations of the symptoms which occur in the early stage of disseminate sclerosis, followed by their partial or complete disappearance for months or even years, are well known and difficult to account for. Arthur Hurst[4] believes that many of the early symptoms are hysterical and that the periods of improvement are the result of some suggestion to the mind of the patient. He says that it is hardly conceivable that sufficient change should occur in the central nervous system to account for the conversion of complete paraplegia into slight stiffness and weakness of the legs, or of total blindness into slightly indistinct vision; that such results are best explained by the influence of some form of psycho-therapy.

But this explanation is scarcely applicable to the rapid and repeated interchange of the reflexes which sometimes occurs in this disease. A remarkable instance of this is recorded by Dixon Mann.[5] Six months after the onset of disease the legs were slightly spastic, the knee-jerks were exaggerated, there was well-marked ankle-clonus, and the plantar reflex on both sides was extensor. Ten days later ankle-clonus could not be obtained and the plantar reflex was flexor on both sides. A fortnight later the plantar reflex was extensor on the left side and flexor on the right. A week later it was again extensor on both sides. The patient improved progressively during the ensuing ten days and left the hospital able to walk with ease. She was readmitted when similar changes in the reflexes were observed.

In commenting on this case Dixon Mann says that responses so immediately contradictory were probably due to the direct action of a toxin on the neurones. He refers to the effect of certain narcotic drugs on the plantar reflex; for example, after an injection of scopolamine the extensor response can be obtained in from 15 to 60 minutes, and may persist for several hours.

Now if it be assumed that a toxin is the causal agent of disseminate sclerosis, and that in the early stages of the disease the toxin is produced intermittently, then we have an explanation for the rapid oscillation of many of the cardinal symptoms, the disturbance of function occurring in waves, corresponding to the intermittent evolution of the toxin and subsiding as each batch of toxin is exhausted.

Such an hypothesis will also explain the temporary duration of an ocular paralysis, which sometimes precedes the typical symptoms of disseminate sclerosis. These ups and downs are not peculiar to this malady. The clinical histories of tabes, general paralysis, and of other chronic nervous diseases are prolific in instances of arrested progress, and of alternating of occupations suitable for the blind was necessary, and not one of the very many wonderful gains in knowledge and experience acquired by the war has been greater than the vista of what can be done in the way of training the blind. The question now is not what the blind may be taught but rather what they cannot be taught, for there seem to be but few heights to which a blinded man, under suitable environment, may not rise, provided he is gifted with the necessary grit and determination to make good. Sir Arthur Pearson, himself a man blinded at middle age, endowed with great intellectual capacity and marvellous powers of organisation, has done nothing so great as this, in that he realised in himself that it was still possible for him to carry on after his loss as well and in some ways better than he had done before. His blindness led him to search his powers, and finding out that he was, as he himself expresses it, "not disabled, but only inconvenienced," he opened a home for blinded officers, and living with them himself he imbued them with the same spirit as himself and tried to show them that it was possible for each to make good in some way.

His efforts were crowned with marvellous success in a large number of cases, and I cannot do better than quote a few examples to show what I mean. One blinded officer, who had been manager in a large industrial firm, was taken back on trial by his firm and successfully proved his capacity to carry on his former duties. This gentleman was later sent to Australia to open and organise a fresh branch of the business, and has now returned after a completely successful trip. Two other officers, also totally blinded, started in company with a third sighted partner as insurance agents, and are doing very well. Another officer has resumed work as a barrister, whilst another endowed with an excellent voice was trained as a professional singer. Many others who had no special gifts were taught poultry-farming, whilst others again learned massage, and passed successfully the same examinations for diplomas as sighted candidates. It must be confessed, however, that the training of blinded officers was in some respects more difficult than that of the men. During the war commissions were given to all grades of society and as a result of their disablement a certain number of blinded officers found themselves in possession of an income considerably larger than they had ever had before. In other words, there was a lack of incentive, in some cases due to the feeling that work was not necessary. Others, again, had ample private means before disablement, and this again, but from a different point of view, tended in a few instances to counteract the desire to make good.

SELECTION OF LIVELIHOOD.

Reverting again to the training of the majority, those who belong to the humbler walks in life, the selection of a suitable livelihood for each requires considerable care. For those who have spent their previous life in manual labour the old trades of brush-, mat-, and basket-making cannot be improved upon, for they are easily acquired, and to these may be added the boot-repairing or "snobbing," as it is termed, the latter proving a great favourite at St. Dunstan's. Carpentry and even joinery, which at first sight seems almost impossible for a blind man, are also taught at St. Dunstan's, and I have seen some wonderful work done by men who had never learnt anything about joinery until they had been blinded. A wise provision at St. Dunstan's is the teaching of two trades of the simpler kinds. Thus the boot-repairer would also learn how to make mats or baskets or vice versa. The employment of blind instructors is a sound practice, because no one understands the particular difficulties of the blind pupil so well as one who has himself experienced them, and thus a certain number of pupils who can attain sufficient proficiency and possess the other qualifications necessary for teaching may obtain a good living in the future by becoming instructors themselves.

I have already alluded to massage and poultry-farming. The former is obviously only open to those who possess some social qualifications and refinement, and moreover, on account of the delicacy of touch required, is unsuited to those who have spent many years at manual toil. Further, there are stiff examinations to pass, and on this account those who have only the usual board school education behind them are unlikely to prove good pupils. The massage class at St. Dunstan's may be said to comprise the pick of the men from the point of view of refinement and education, and the success that has attended the classes has been extraordinary. For some time past there has been an Association of Certificated Blind Masseurs, and all recent reports show what an unqualified success the exploitation of massage for the blind has been, and no doubt will always continue to be. Poultry farming is another original and most successful experiment. At the outset this was personally superintended and taught by Captain Webber, himself totally blind for many years. Captain Webber discovered this as an amusement, and by practice attained a quite uncanny power of dealing with poultry, at which a sighted man could only marvel. In the poultry class the men are practically taught by lectures and demonstrations everything that appertains to a poultry farm. A farm was run in the grounds of St. Dunstan's and here the men learned to handle and appreciate the different kinds of fowls, to prepare them for table, the secrets of successful breeding and prolific egg production, and in fact everything that a sighted man might know on the subject. The success of the teaching has been abundantly proved by the number of blind men who are to-day successfully putting their teaching to the practical test of running their own farms.

Then, again, for those gifted with a musical ear, pianoforte tuning has for long been recognised as a suitable calling, but the field of employment is rather limited. Telephony has been a successful experiment for some of the better educated, and expert telephonists have been turned out. I have myself always hoped that cigar and cigarette making would come to be numbered amongst suitable employments, but so far I do not think this trade has been tried. I have no doubt as time goes on fresh fields of work will open out, for the interest of the nation has finally been aroused, as is shown by the formation of a Government Department devoted to the welfare of the blind. It is, indeed, as much to the good of the community at large as to the blind themselves that the latter should become good independent citizens.

DIFFICULTIES EXTRANEOUS TO LOSS OF SIGHT.

The training of the blind presents certain difficulties beyond those directly connected with loss of sight. Thus, owing to the more intense concentration of mind required, the hours of work must necessarily be much limited, especially at first. Later on as the work becomes more automatic the blind person can gradually extend the hours of continued labour, but if the work involves much mental exercise it is bound to tire and strain much more than would be the case in a sighted person. At St. Dunstan's, where of course a great many men had experienced severe head and face injuries, the inability to concentrate for more than a very limited period was apparent, and the work-time was limited to two hours in the morning and two hours in the afternoon, and even this proved too long for many of the patients. And as the hours of work must be shorter than normal, so the necessity of filling in spare time becomes of great importance. I have already dwelt at some length on the necessity and usefulness of these relaxations, and need say no further beyond that all St. Dunstan's people are taught string-bag making and netting, employments which need but little mental concentration and afford interest, amusement, and, if need be, some profit. Reading aloud is another great pleasure to many blind people, and good readers will always obtain an appreciative audience. Cards marked with Braille notation enable those fond of this amusement to capable of misinterpretation. It would be of no value to go over in detail the list of cases excluded; even if the reasons were given in every instance difference of opinion would still exist. But even if the results reached in this investigation may be attacked by the strict statistician they point to general conclusions of interest and value, and it will be shown that these conclusions do not materially depend on the selection and rejection of the cases.

Of the private cases, 134 were rejected as obvious or trivial, leaving a total of 660. None of the Institute cases were put aside, as all were of interest. Adding the 314 Institute cases to the 660 private cases we have 974 cases in all. It seemed to the Committee that this material was sufficient for our immediate purpose. It would be an easy matter to deal with all cases in future if we could devise some useful method of classification. The difficulty was to find some principle on which to proceed.

Two Classes of Case Presenting Special Difficulty.

At the outset two classes of cases which we had retained on our list presented a difficult problem.

1. *Cases of Pregnancy.*—In several instances the patient came for advice not because of pregnancy, but because of certain symptoms of which the explanation was not obvious. For the determination of pregnancy and the exclusion of disease careful examination was necessary. This surely is a type of successful diagnosis, not indeed of disease but of health, or rather of a physiological condition which sets up its own reflexes and is capable of disturbing many others. To what extent this disturbance may occur without some associated condition of ill-health may be beyond the possibility of definite determination; it is therefore a matter of individual opinion whether a pregnancy is strictly normal or not.

2. *Cases of Physiological or Functional Cardiac Murmurs.*—If a patient presents a sign or symptom suggestive of disease but now known to be compatible with perfect health, and if after the most careful examination no associated symptom pointing to disease is detected, the conclusion is reached that he must be regarded and treated as a person in normal health. That this is an invaluable type of diagnosis in view of the patient's future in life cannot be denied; it therefore finds a place in our classification. There is little doubt that in connexion with suspected disease in other organs there may be symptoms, now regarded as of grave significance, which in the future will be found to be of little or no importance; meanwhile we consider only cardiac murmurs, and in all cases where they were judged to be of no significance we have had the assistance of Sir James Mackenzie's special knowledge and wide experience in making the decision.

Consideration of these two classes of cases makes plain the constant possibility of error, and in fact difference of opinion occurs in a large proportion of cases. But for our purpose it is necessary to accept the opinion of the doctor concerned when he claims to have reached a diagnosis. It is inevitable that in an often necessarily brief consulting-room examination, some fact essential to a diagnosis will be overlooked from time to time; more frequently, no doubt, a diagnosis is reached which a more prolonged investigation would not have warranted. But it appears unlikely that in the present state of medicine there would be any great dissimilarity in the proportions of diagnosed and undiagnosed cases in many series of investigations such as we have made. The proportion depends not on the skill or training of individual practitioners, but on the unsatisfactory state of all medical knowledge.

Definition of Diagnosis.

What has been written so far is largely introductory. We now come to the difficult question: What is a diagnosis? There is no general agreement as to the meaning of the term. From its derivation it might be taken to mean either a complete knowledge or a knowledge sufficient for the purpose of separation or differentiation, according as we translate "dia" as "thorough" or "through." If no case can be regarded as diagnosed unless the physician has a thorough knowledge in all its aspects of the disease from which the patient is suffering, it is obvious that the percentage of cases diagnosed must approach the vanishing point. Diagnosis has been defined as "the discrimination of diseases by their distinctive marks," or "the differentiation of diseases by their distinctive symptoms." But such a definition is confusing, for we do not imply that the differentiation of diseases is impossible when we say that cases are undiagnosable. For the purpose of this investigation we define diagnosis as "the recognition in the patient of a known disease from the symptoms which are characteristic of it." If he exhibits a well-defined group of symptoms distinctive, so far as present knowledge goes, of one disease only, his case can be diagnosed. The physician fails in diagnosis if he does not recognise these symptoms when they are present, or if he assumes that they are present with insufficient evidence; it cannot be said that his diagnostic powers are at fault if the case shows no such characteristic symptoms. The differentiation of diseases has not gone far enough to enable him to understand or even to name the condition. The most prominent symptom may be chosen and the disease named after it, or a variety of symptoms may be selected and the patient shown to be suffering from a complication of troubles. The latter plan is tempting because it makes the difficulty of the case apparent both to the patient and to his friends, and explains the necessity for practically any variety of treatment that may be adopted. In these days, when the doctor is almost forced to give a name to the illness either by panel authorities or anxious relatives, such a multiplication of terms may be useful, but it is certainly demoralising.

Ætiology and Diagnosis.

There is another matter in regard to diagnosis which merits consideration. From the point of view of diagnosis, knowledge of the cause of the disease which has been recognised is not essential. With the question of ætiology diagnosis is not immediately concerned. If in addition to the well-defined group of symptoms the noxious agent causing injury to the organism is known, or if its nature can be reasonably inferred by analogy from other diseases showing similar symptoms and a similar course, our knowledge of the disease is much more satisfactory, but this question is not primarily one of diagnosis or recognition. Definite diseases have, in fact, in practically all cases, been separated by their distinctive symptoms, and their diagnosis made possible without error, before the nature of the agent at work has been discovered. Typhoid fever, for example, was diagnosable before the typhoid bacillus was found. It is the work of the clinician to separate diseases by their characteristic symptoms in order to give the chemist, bacteriologist, or other laboratory worker the opportunity of making his special investigations with regard to them.

Diagnosis and Treatment.

The relationship between diagnosis and treatment suggests itself at this point. The objects of diagnosis are prognosis and intelligent treatment, and for the treatment of any disease recognition of symptoms and interpretation of their cause are necessary from day to day. A sufficiently definite group of symptoms may be present to enable a perfect diagnosis to be made, but all the symptoms of a disease are not present at once; they must all be watched for, though some may never appear. A lesion may occur which, though itself a symptom, can produce secondary symptoms of its own and modify the whole outlook. In acute rheumatism symptoms of endocarditis may or may not be present, and are not necessary for the diagnosis; but the occurrence of endocarditis at any stage of the disease is a matter of the gravest importance as affecting both prognosis and treatment. In

Quite a number of elderly men past 50 years of age who volunteered for labour work during the war were blinded as the result of their unselfish patriotism, and for a certain number of these, together with some who were mutilated in other ways besides being blinded, a permanent and beautiful home has been found at Ilkley in Yorkshire. Here they are maintained in comfort and everything possible is done to mitigate their lot.

THE PROBLEM OF MARRIAGE.

There is one more point of real importance and much difficulty, and that is the marriage of the blind. Every young blinded adult of the male sex very badly needs a partner who can look after him and supervise the numberless details of life, such as dress, appearance, food, and cooking, &c., who, in fact, can make a home for him. And yet to marry a blind man is a very serious step for any girl to take. She probably has it in her power to make him happy or utterly miserable, and to attain the former she must be content absolutely to give up her life to him. There is no middle way, and, therefore, though marriage is highly desirable, the girl must be of the right sort, and the problem is to find her. Many marriages with blind men have taken place during the war, and though some no doubt are proving idyllic, yet I know of others much the reverse, and then the state of the blind partner, or perhaps of the sighted partner, is indeed desperate. I remember one instance where the girl, who had been engaged to the man before he lost his sight and who had married him from pity, told me that she had come to loathe her husband. She was desperately anxious to conceal the fact from him, and naturally was desperately unhappy; they had only been married 18 months and were both fairly young. For blinded girls the situation is rather different. As a rule there is not the same necessity for them to earn their living independently, and they can generally find a home and shelter.

For the young of both sexes who are unmarried, communal settlements run on the lines of clubs are the ideal thing, if there are no parents or relatives to provide a home. To dwell in dreadful isolation in lodgings is indeed a doom to inspire despair, and I hope that in the near future some attempt will be made to start Blind Clubs to shelter these unfortunates.

THE THIRD CLASS OF UNFORTUNATES.

And, lastly, just a word with regard to the third class of cases of which I made mention—viz., those who still possess some useful sight, but insufficient to enable them to earn their own living. A certain number of these cases are in some ways more unfortunate than those who are completely blinded. Many are the cases to whom I have had to refuse admission to St. Dunstan's simply because training would simply mean total loss of what they still had left. A person who can see cannot be taught to work without using his eyes. It is of no use to tell such a person not to look at the work or to bandage the eyes so that he cannot see. If the eyes are not bandaged they will inevitably be called into play upon every little difficulty—i.e., at just the very time when sight is most needed and when it will be especially strained. Bandaging the eyes makes matters rather worse, for the necessary mental concentration will of necessity produce the reflex physical concentration of the eye behind the bandage, and the ultimate result in a very short time is a headache and aching eyes. Then there are others of the same class who can learn a trade without any special harm to the sight, but whose sight gets quickly exhausted, so that it is impossible for the person to work sufficiently long hours to earn a living wage. One really does not know what is the solution for these cases. St. Dunstan's has in many of them come forward with pensions which provide a sufficiency with external help from other sources, such as friends, or the money that a wife may earn; and, so far as I can see, State pensions are in the future the only way by which many persons of this class can be kept from pauperism.

THE SIGNIFICANCE OF SOME EARLY SYMPTOMS OF NERVOUS DISEASE.*

BY JUDSON S. BURY, M.D. LOND., F.R.C.P.,
VISITING PHYSICIAN TO THE NEUROLOGICAL HOSPITAL FOR PENSIONERS AT BRINNINGTON; CONSULTING PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

THERE is no study more fascinating than that of the early symptoms of disease, no problem more difficult to solve than that of their significance. At first it seemed an easy matter to collect out of my experience a series of cases which would enable me to draw some instructive conclusions, but in thinking over my observations I found that the undertaking was going to be difficult, entailing a reconsideration of the meaning of the terms "functional" and "organic," and of the respective significance of subjective and objective symptoms, and that the experience, largely derived since the year 1914, of a psychical factor and of the alleged rapid cures of many nervous disorders by psycho-therapy must be taken into account.

I will limit my remarks mainly to a consideration of pain, numbness, motor disability, and the plantar reflex.

Pain.

The significance of pain varies greatly, partly according to the situation of the lesion, but chiefly in consequence of the varying susceptibilities of the nervous system in different individuals. The course of an intrathoracic aneurysm or of a pyloric cancer may be unattended by pain, and one has seen cases of cerebral tumour in which headache was but slight and certainly far from constant.

Pain in the head, a prominent feature in many of the war neuroses, has been, in some cases, severe and constant, and in these respects indistinguishable from the typical pain of an intracranial tumour. In both instances there may or may not be tenderness on pressure over the painful area; the diagnosis must therefore be based on other aspects of the case. But it is necessary to remember that the presence of a growth may be expressed for a long time by subjective symptoms only, all objective signs of a nervous lesion being absent. Many years ago I had the opportunity of following from beginning to end a case of endothelioma,[1] growing from the dura mater of the right middle fossa of the skull. During the first 16 months, although repeated examinations of the patient were made, the symptoms were entirely subjective, the chief symptom being severe and almost constant headache, made worse by movement and noise. The patient suffered also from nervousness and giddiness; he slept badly and was troubled with horrible dreams. These symptoms are similar to or identical with those of some of the war neuroses, and it is possible that a psycho-analyst might have felt justified in undertaking the treatment. In the seventeenth month and onwards for the next three months till the patient's death, there were definite signs of an intracranial lesion—namely, of implication of the third, fourth, fifth, sixth, and eighth nerves on the right side, and of the seventh and twelfth on the left side. Vomiting and optic neuritis were absent from first to last. Many similar instances of long duration of subjective symptoms in serious disease without objective signs might be mentioned.

During an interview with a patient who complains of headache or other subjective symptoms, we receive, as a rule, impressions from his facial expression, the manner of speech, general behaviour, attitude and movements which unconsciously influence us to decide in favour of or against the presence of serious disease. It is important to subject such impressions to close scrutiny in the hope that we may discover adequate reasons for them; at the same

---

* This communication was given at a meeting of the Association of Physicians in Birmingham.

The following is a complete list of Class 1; recognised causes are given in italics:—

Institute (34 cases).

Adenitis (*carious molar*).
Ascariasis.
Dysentery, 2 cases.
Diphtheria (exhaustion following).
Gunshot wound (shrapnel in neck: pain).
Hernia, 2 cases.
Headache (*refractive error*).
Headache (*involvement of nerve-endings in scar*).
Heart, congenital, 2 cases.
Laryngitis (*excessive use of tobacco*)
Neuritis—peripheral (*lead poisoning*).
Phthisis pulmonalis, 9 cases.
Pleurisy—traumatic, 2 cases.
Pulmonary impairment (*injury*).
Prolapse of uterus.
Rupture of spleen.
Renal colic (renal calculus).
Syphilis, 2 cases.
Systolic murmur—physiological, 2 cases.
Tuberculosis of bones.

Private (77 cases).

Alcoholism.
Alcoholism, gastritis.
Abscess of auditory meatus, 2 cases.
Adenitis (*carious teeth*).
Amblyopia (*tobacco*).
Abscess of toe (following *injury*).
Cartilage loose, semilunar.
Conjunctivitis (*burn*).
Contusion of chest.
Contusion of sternum.
Contusion of metacarpo-phalangeal joint, verified by X rays.
Concussion of brain.
Diphtheria, 2 cases.
Epididymitis, gonorrhœal.
Epididymitis (*tuberculous*).
Fracture of tibia, partial (X rays).
Fracture, greenstick.
Fracture of clavicle, 2 cases.
Fracture, old (X rays).
Fracture of patella, 2 cases.
Gingivitis (*carious teeth*).
Gonorrhœa, 2 cases.
Hernia, 4 cases.
Headache (*refractive error*), 2 cases.
Impetigo contagiosa, 7 cases.
Malaria.
Obstruction of parotid duct.
Pneumonia—Empyema.
Pneumonia, 2 cases.
Periostitis of tibia (*traumatic*).
Pregnancy, 6 cases.
Prolapse of uterus, 3 cases.
Phthisis pulmonalis, 5 cases.
Ringworm.
Sapræmia (following *curettage*).
Septic cellulitis (following *scratch*).
Synovitis of shoulder (*traumatic*).
Synovitis of knee (*traumatic*).
Syphilis, 5 cases.
Strain of muscle.
Systolic murmur—functional.
Talipes valgus.
Thrombosis (following *typhoid*).
Tuberculosis *of* glands of neck.
Tuberculosis of joints.
Ulcer of lip (*tooth*).

Class 2 (Fig. 4).—This is a small class. Included in it are trench fever, influenza, acute rheumatism, measles, and German measles. It would be considerably smaller but for the fact that we have included rheumatoid arthritis, a very doubtful decision. There are no cases of scarlet fever; many cases which formerly would have been diagnosed without hesitation as scarlet fever have probably been relegated to some other category. It might indeed be argued with some weight that scarlet fever is not a distinct entity at all. These matters are only mentioned to illustrate the fact that finality in classification is impossible. In this class are placed 7 (2·23 per cent.) of the 314 Institute cases, 13 (1·97 per cent.) of the 660 private cases, and 20 (2·05 per cent.) of the total 974 cases. The following is a complete list of Class 2:—

Institute (7 cases).

Encephalitis lethargica.
Poliomyelitis anterior acuta.
Rheumatoid arthritis, 4 cases.
Trench fever.

Private (13 cases).

German measles.
Influenza.
Measles.
Rheumatism, acute, 6 cases.
Rheumatoid arthritis, 3 cases.
Trench fever (pains in shins following).

Class 3 (Fig. 5).—This is a larger group, approximating in size to Class 1; the numbers are swelled by the inclusion of rheumatic cases—not all those cases which might be casually labelled as rheumatic, but those with a sufficiently definite picture, Prof. R. Stockman's definition being taken as the standard. To select such cases is very difficult: probably we included too many, as the term rheumatism is sometimes applied without sufficient investigation. Examples of other diseases in this class are Hodgkin's disease, exophthalmic goitre, asthma, epilepsy, gall-stones disease, and myeloid leukæmia. It is of some interest to note that herpes zoster, which we include in this class, is now thought by some to have a close relationship to chicken-pox, which would be placed in Class 2. Many of these cases showing interesting symptom-complexes were brought to the Institute for fuller examination, which accounts for the larger proportion on the Institute list. In Class 3 were placed 34 (10·82 per cent.) of the 314 Institute cases, 51 (7·72 per cent.) of the 600 private cases, and 111 (8·72 per cent.) of the total 974 cases. The following is a complete list of Class 3:—

Institute (34 cases).

Acidosis.
Asthma, 3 cases.
Epilepsy, 2 cases.
Exophthalmic goitre, 2 cases.
Gall-stones disease, 3 cases.
Habit spasm.
Herpes zoster, 4 cases.
Hodgkin's disease.
Hysteria.
Insanity (inhibitional).
Migraine, 2 cases.
Myeloid leukæmia.
Myxœdema.
Recurrent mania.
Recurrent vomiting of childhood, 2 cases.
Renal colic, 2 cases.
Rheumatism, 6 cases.

Private (51 cases).

Asthma, 6 cases.
Asthma and emphysema.
Convulsions of infancy.
Eczema, 3 cases.
Epilepsy, 4 cases.
Erythema multiforme.
Exophthalmic goitre, 2 cases.
Gall-stones disease.
Herpes zoster, 6 cases.
Migraine, 4 cases.
Myxœdema.
Pemphigus.
Rheumatism, 13 cases.
Urticaria—asthma.
Urticaria, 6 cases.

Class 4 (Fig. 7).—In this class we place end-results, by which we do not mean the concluding stages of known progressive disease, for example, phthisis, but conditions of permanent damage to organs or tissues, the original noxious agent, whether known or unknown, having ceased to be of importance and the damaged organ itself being now a noxious agent giving rise to symptoms of disease. Examples of this class are angina pectoris, auricular fibrillation, adherent pericardium, heart-block, and cases of malignant disease. At present we are unable to diagnose malignant disease in its initial stages, but it is necessary to detect the damage it has caused at the earliest possible moment in order to give the surgeon his opportunity. In this class were placed 45 (14·33 per cent.) of the 314 Institute cases, 14 (2·12 per cent.) of the 660 private cases, and 59 (6·05 per cent.) of the total 974 cases. The much higher percentage in the Institute cases is explained by the fact that few advanced cases requiring confinement to bed were recorded, and that the great majority of those able to move about were taken to the Institute for examination. The following is the complete list of Class 4:—

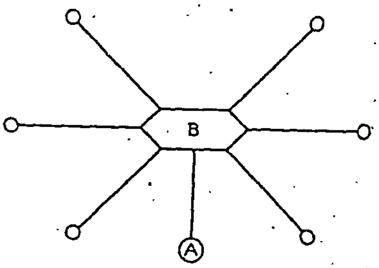

FIG. 7.—A represents the original noxious agent. B represents the permanently damaged organ or tissue. The circles at the periphery represent the symptoms or reactions.

Institute (45 cases).

Adherent pericardium.
Angina pectoris, 8 cases.
Arterio-sclerosis, 2 cases.
Auricular fibrillation, 5 cases.
Auricular flutter.
Cardio-sclerosis, 4 cases.
Heart-block, 4 cases.
Intermittent claudication with auricular fibrillation.
Malignant disease, 5 cases.
Senility—alcoholism.
Senility—rectal prolapse.
Spastic paraplegia, 2 cases.
Valvular disease of heart, 10 cases.

Private (14 cases).

Angina pectoris, 2 cases.
Aortic regurgitation.
Arterio-sclerosis—occlusion of posterior tibial artery.
Auricular fibrillation, 4 cases.
Epilepsy (following injury to head).
Heart-block.
Malignant disease, 2 cases.
Senile dementia.
Senile hemiplegia.

Class 5 (Fig. 8).—In this class are included cases in which a definite local lesion or morbid condition exists, giving rise to symptoms—the noxious agent causing the mischief being unknown, and no uncoordinated symptoms being present, so far as can be determined at the time of examination, indicative of more widespread disease. The lesion may be visible, or inferred with practical certainty, from the symptoms observed. Such cases form a large proportion of those met with in general practice, and among them the doctor meets with his greatest successes as well as his most grievous disappointments. His treatment is symptomatic, and he awaits the outcome to show whether or not his diagnosis, easily made because all these conditions have been labelled periods of improvement and breakdown. Surely such ebbs and flows cannot be put down to variations in psychical influences—important as such influences are in modifying the course of every disease—unless we admit that they may increase the output of antitoxins, or in some other way check the action of the toxic agent. I should be the last to deny the influence of minute lesions of nerve tissue in exciting an outbreak of hysterical symptoms in persons who have an abnormal suggestibility. There is also reason to believe, as I have stated in a previous communication,[6] that emotional disturbance is an important ætiological factor in maladies other than the neuroses; for example, cases of chorea, paralysis agitans, and pernicious anæmia have developed immediately or soon after a fright or other emotional shock. Indeed, we may admit the possibility that hysteria itself can initiate changes which progress into detectable lesions. Charcot assumed that lateral sclerosis might occur as a direct outcome of changes started by hysterical contractures of long duration. Moreover, if cutaneous blisters can be produced by "suggestion," as recently stated by Dr. J. A. Hadfield,[7] why not exudations into the spinal cord? Are we quite certain that a true extensor plantar response is never the result of the effects of hysteria? At the present time I have an hysterical patient whose knee-jerks cannot be elicited. The Wassermann reaction is negative, and there are no signs of disease, either of the nerves or of the central nervous system.

At the end of his charming little book, "On the Simulation of Hysteria by Organic Disease of the Nervous System,"[8] Thomas Buzzard says, "the figure of hysteria shrinks in proportion as the various forms of organic disease acquire greater solidity and sharper definition."

In contrast to this view the present-day psychotherapeutist might say: "The figure of hysteria enlarges in proportion as the various symptoms attributed to organic disease are found to disappear under the influence of psychotherapy."

Conclusion.

But whichever view is held, the danger of suggesting symptoms to the patient must not be allowed to hamper the close clinical investigation of all his complaints; full consideration must be accorded to transitory manifestations of disease, and if a decision is given in favour of hysteria, the possibility of future developments must not be overlooked; subsequent examinations of the patient must be as thorough as the first examination, and quite unbiased by the first diagnosis of hysteria.

DONATIONS AND BEQUESTS.—Mr. Walter Beer, cotton merchant, Liverpool, left estate of over £190,000. The testator left £200 each to the Old Hebrew Congregation, Princes-road, Liverpool; the David Lewis Northern Hospital; the Royal Southern Hospital, Liverpool; and the Liverpool Royal Infirmary; £100 each to the Liverpool Dental Hospital; the Liverpool Hospital for Cancer and Diseases of the Skin; the Liverpool Eye and Ear Infirmary, Myrtle-street; the Liverpool Infirmary for Children; the Stanley Hospital, Liverpool; St. Paul's Eye Hospital, Oldhall-street, Liverpool; the Leasowe Sanatorium for Crippled Children; and the Liverpool Hebrew Ladies' Benevolent Institution.—Under the will of the late Dr. Charles A. Hingston, of Plymouth, the Y.M.C.A., of which he was a leader in the western counties, will benefit by the acquisition of property in Plymouth as well as by legacies of money. The testator, among other bequests, also left £2000 to the Convalescent Home, Crown Hill, Plymouth; £500 to the Plymouth and District Deaf and Dumb Institution; and £200 to the Plymouth Public Dispensary.—The Board of Management of the Royal Infirmary, Manchester, have received £2833 from the local Hospital Sunday Fund, a legacy of £200 from the late Mr. Joseph Core, of Manchester, and other sums from various sources to the amount of £626.

STUDIES FROM THE ST. ANDREWS INSTITUTE OF CLINICAL RESEARCH.

Preface by SIR JAMES MACKENZIE, F.R.S.,
DIRECTOR OF THE INSTITUTE.

THE prime object of research in this Institute being the prevention of the diseases common among the people, the question arose as to what might be these diseases. A preliminary inquiry had revealed the insuperable difficulty of obtaining this knowledge; a more elaborate inquiry was determined upon, but it was soon found impossible to arrive at a knowledge of the diseases themselves. The inquiry therefore took the form of an investigation into the state of medical knowledge concerning them. The three studies which follow are the outcome of the inquiry undertaken by the members of the clinical staff of the Institute, with Dr. Andrew Rowand as chairman, a complete report of which is to be published shortly.

I. PRESENT STATE OF MEDICAL KNOWLEDGE REGARDING THE DISEASES COMMON AMONG THE PEOPLE.

BY ANDREW ROWAND, M.B. EDIN.

The following paper is the outcome of the inquiry in what proportion of the cases met with in general practice it is possible to arrive at a diagnosis. A series of cases was taken from the records of general practice in St. Andrews; the series was consecutive, and no selection was made from the cases. The time and care given to them had been limited by the demands made on two general practitioners doing their routine work; the notes were made at the time the patients were seen, and were not afterwards elaborated. In the majority of cases the patients were seen in the consulting room, and so were not suffering from acute or advanced disease requiring confinement to bed. There was no epidemic at the time.

The cases examined numbered 896; as 102 of them had been referred to the Institute for more thorough examination, or for examination in the special departments, and so appear in the records of the Institute, they were deducted from the practitioners' lists and included in a series of 314 Institute cases which were examined in the same way. As the great majority of the private cases were able to move about there was a similarity between the two series, there being no beds in the Institute, but as many advanced cases were brought to the Institute because of some special interest in their symptoms, or for the benefit of examination in the special departments, fewer of such cases appear in the lists of the practitioners than would otherwise have been the case. There is no essential difference between private and Institute cases; the main object of the Institute is to assist the practitioner in the investigation of the early diseases and vague ailments which he meets from day to day. The terms "private" and "Institute" are adopted for convenience; all the cases are private patients.

Preliminary Selection of Cases.

The first step taken was to put aside from the private records a number of cases which might be regarded as so obvious that the diagnosis was self-evident, or so trivial as to be of no interest in the investigation. The selection proved to be a matter of extreme difficulty, and it is questionable if it was wise to attempt it. Each case was considered on its merits, so that in one case a condition has been excluded as obvious, while in another it has been retained. Hernia, for example, appears in the lists both of the selected and the rejected. A hernia is obvious when the patient is aware of its presence and comes to the doctor to have a truss adjusted; but it is a different matter when its existence is revealed on examination and is found to explain symptom

The marked difference between the proportions in the Institute and private lists is due to the large number of Class 4 cases brought to the Institute.

The following figures show the results obtained by retaining all the cases which passed under review and including in Class 1 all those previously rejected as trifling or obvious. We are now dealing with all the conditions on account of which the doctor is consulted, for notes were kept even of slight cuts, toothache, and wax in the ears. The Institute list is unaffected as none of the Institute cases were omitted.

	Institute.	Private.	Total.
Number of cases	314	794	1108
Cases diagnosed	120	289	409
Proportion diagnosed	38·21 %	36·40 %	36·90 %

Conclusions.

Although there is much room for difference of opinion with regard to the allocation of a particular case to a particular class, it was found that after much reconsideration of the cases and transferences from one class to another the proportions in the various classes varied to a very small extent. The most marked features in the results of the investigation are:—

1. The demonstration of the chaotic condition of the present classification of diseases.
2. The small proportion of diagnosed cases, even when these include all the cases in which the diagnosis was self-evident.
3. The small proportion of cases in Class 1, even when there are included in it all the obvious and trifling cases.
4. The very large proportion of cases in Class 6.

THE PSYCHO-PATHOLOGY OF PULMONARY TUBERCULOSIS,

WITH SPECIAL REFERENCE TO TREATMENT.

By D. G. MACLEOD MUNRO, M.D., M.R.C.P. EDIN.,
DEPUTY COMMISSIONER OF MEDICAL SERVICES, LONDON REGION, MINISTRY OF PENSIONS; LATE TUBERCULOSIS MEDICAL OFFICER, COUNTY COUNCIL OF MIDDLESEX; RESIDENT PHYSICIAN, ROYAL VICTORIA HOSPITAL FOR CONSUMPTION, EDINBURGH.

ALTHOUGH there is probably no disease in which mind and body are in such close co-relation, it is altogether surprising to note how little attention has been paid to this intimacy of association, more especially as affecting the treatment of pulmonary tuberculosis; while in the matter of prognosis the psychic make-up of the patient, and his mental outlook, are also factors of no small significance. In this connexion I do not now especially refer to that state of euphoria in advanced cases so dwelt upon by a certain type of novelist, and popularly known as the "spes phthisica"—which is not the mental habit of the average patient suffering from pulmonary tuberculosis—but to certain well-recognised and clearly defined psychic changes, which are the accompaniments of this disease. I am fully aware of the fact that there are differences of opinion on the question as to whether the psychology of the phthisical patient diverges to any greater extent from the normal than in the case of certain other prolonged and debilitating illnesses; but my own experience, and I think that of many observers, goes to show that there is what may be called a specific psychoneurosis in pulmonary tuberculosis. By some, this has been grouped under three headings: (1) The hereditary type; (2) chronic phthisical type; (3) advanced type. It has further been suggested—adopting Freudian terms—that in place of sex-consciousness, there is what has been described as a sense of "organ insufficiency." It is no part of my intention, however, in these remarks to elaborate this side of the question; I wish rather to call attention to certain well-marked features of the psychic state of the average phthisical patient, and to see in what way these bear upon, and can be influenced by, treatment.

In general the mental reactions of the phthisical patient may be said to indicate a reversion to the congenital or infantile type, and such suppression or modification of these as may have resulted from environment and education is largely abolished. While many become introspective, selfish, egocentric, weak-willed, and lacking in self-control, it must be added that not a few become morally stronger as a result of the self-abnegation called forth in the course of the long battle for health. It is not surprising indeed that, in a disease so protracted in the average case, we find undermining of the will-power and a less complete control of the emotional side. It is still an open question whether these changes indeed are to be regarded as a result of the debilitating effects of the disease, or as consequent upon the specific action of the endotoxins of the bacillus tuberculosis. It does not appear to me inappropriate, in this connexion, to refer to certain other very definite psychic and intellectual changes which in some instances are a marked feature of this disease. There seems no reason to doubt, for instance, that even in those of just ordinary intellectual attainments, there is at times a species of mental exaltation with an added keenness of intellect of which no adequate explanation has been offered unless we accept it as resulting from the prolonged intoxication set up by the endotoxins of the bacillus. In those of literary and artistic attainments this psychic and mental excitation has been found to occur in marked degree, and in the long and tragic roll of men and women of genius who have suffered from this disease nothing is more striking than the fact that the creative powers of the mind have been at their highest at a time when the disease was active and progressive. Art and literature would have been indeed impoverished without the names of Keats, Chopin, Charlotte Brontë, Stevenson, Symonds and Francis Thompson, to mention only a few of the army of stricken genius. Explain it how we may, there can be little doubt, I think, that in some remarkable manner, enhanced productivity, quickened intellect, and imaginative power, have marked the trail of the tubercle bacillus in such persons. Although possibly in the nature of a digression, these facts are of much interest in a study of the psychology of this disease.

"*Suggestibility*" *of the Condition.*

With the exception of the functional neuroses there is perhaps no disease in which susceptibility to suggestion is so high as in pulmonary tuberculosis—a point I wish to emphasise—and in few diseases can this "suggestibility" be utilised so potently for good or evil. As illustrating this perhaps two typical instances well known to everyone may be mentioned. The first which, for want of a better term, comes under the heading of "auto-suggestion," is seen in certain advanced cases with pronounced toxæmia and high temperature. In these cases the patient expresses himself as "feeling splendid," and is engrossed in plans for some big commercial enterprise, a trip round the world, or even a matrimonial venture. The other is a simple example of "hetero-suggestion" in the case of a patient who has been under treatment by tuberculin, and in whom the subcutaneous injection of sterile water is followed by a febrile reaction in all particulars identical with that produced by the administration of tuberculin.

Unfortunately this high degree of "suggestibility" has often opened the door for the exploitation of the victims of this disease at the hands of the charlatan with his infallible "cure" for consumption, and the "treatment" in these cases is too frequently carried out by the patient with a faithful, if pathetic, persistency. But are we as a profession entirely above reproach in this matter? What is to be said of the ever-lengthening array of remedies, from Koch's tuberculin onwards, which have from time to time been hailed as specifics? Have we not as a profession adopted and fathered them with a too easy credulity, sense it is itself a disease. The diagrams (Figs. 1 nd 2) illustrate this point.

We say that we diagnose the endocarditis from its wn characteristic *symptoms. The use of the word* n this secondary sense may appear to introduce onfusion, but it is unavoidable. It is, however, ecessary to keep clearly in view the distinction etween a disease and a symptom, and to hesitate to ccept as a diagnosis of disease what, even in the bscure light of our *present knowledge, is probably* nly the name of a symptom. As knowledge advances *many diseases now regarded as primary* will certainly be found to be secondary, and what is a primary diagnosis to-day may be a secondary diagnosis to-morrow. This matter will receive further consideration later.

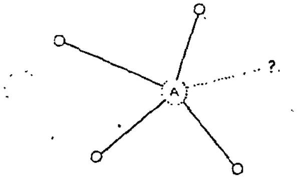

FIG. 1 shows the symptoms which enabled the *primary diagnosis* to be made, and indicates the necessity of watching for further symptoms.

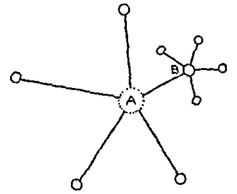

FIG. 2 shows in addition the presence of endocarditis.

In Figs. 1, 2, 3, 4, A represents the noxious agent. *The circles at the periphery represent* the symptoms or reactions.
B represents endocarditis with its own group of *symptoms.*

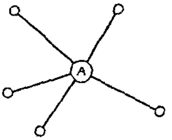

FIG. 3 represents a disease where A, the agent acting injuriously on the tissues, is recognised, and produces reaction or symptoms which are represented by *circles at the periphery.* Examples given by Sir James *Mackenzie are typhoid* fever and conjunctivitis due to a foreign body in the eye.

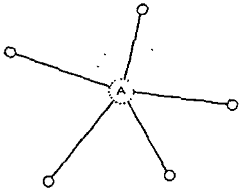

FIG. 4 represents a disease where, *while the symptoms* are recognised, the injurious agent A has not been recognised, though its nature can be inferred. The examples *given are* measles and scarlet fever.

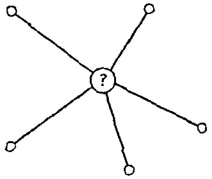

FIG. 5 represents a disease with a well-defined group of symptoms, but where the nature of *the* agent is not recognised. The examples given are migraine and convulsions. ? represents the noxious agent, the nature *of which is unknown. The circles* at the periphery represent the *symptoms or reactions.*

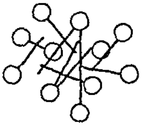

FIG. 6 represents the vast majority of diseases, where a number of *uncoördinated symptoms* are present *with no recognisable* cause.

Classification of Diseases.

Diagnosis is only possible in so far as diseases have been differentiated and classified. The differentiation of diseases is lamentably inadequate; some new basis of classification must be found to save us from the increasing complexity and confusion which are the despair of the medical practitioner. Sir James Mackenzie, in his study of "*The Theory of Disturbed* Reflexes in the Production of Disease," has separated diseases into four classes, as shown in *Figs. 3, 4, 5, 6.*

We regard all cases that can be grouped under the first three classes as diagnosed. Whether the noxious agent be known, inferred, or unknown, the disease can be diagnosed if it presents a distinctive group of symptoms. The cases which can be fitted into Class 1 are the most satisfactory in the sense that the diseases from which they suffer are the most thoroughly understood, but we *take as the criterion* of diagnosis the recognition of a perfectly definite group of symptoms belonging, *so far as* our present knowledge goes, to one disease and one disease only. Cases falling into Class 4 are undiagnosable.

We have extended this classification, not in order to amplify it as a classification of diseases, but to form a classification of the cases with which the doctor has to deal in his ordinary work. We have added two groups, and the question of diagnosis will be considered with regard to them also. Of the six classes, Nos. 1, 2, 3, and 6 are Sir James Mackenzie's four classes of diseases. There will inevitably be difference of opinion with regard to our allocation of cases to different classes, *but there is no finality* in any classification, and if this study of the subject of *diagnosis* does no more than bring this fact into prominence it will have served a useful purpose.

Class 1 (Fig. 3).—The standard example of diseases belonging to this class is conjunctivitis due to a foreign body in the eye. Few cases, apart from those generally regarded as obvious, approach this standard. Renal colic due to renal calculus is a good example, *and we include, of course,* the microbic infections. But the noxious agent in these cases may or may not be the primary cause of the disease: it is no doubt a necessary agent, but it may not stand alone or even be of chief importance. There must be some other element not *at present understood. The presence of the* pneumococcus in the respiratory secretions is no evidence that the patient is suffering from *pneumonia;* when the clinical symptoms of the disease are present it is superfluous to search for the germ. We have *little* idea of the conditions *under which the pneumococcus,* apparently ubiquitous and generally *innocuous,* can become malignant. Other examples of the class are tuberculosis, syphilis, dysentery, *malaria,* diphtheria, and ringworm.

As has been *already mentioned, we have included* many cases which, though simple in nature, cannot in our view be regarded *as necessarily trivial or obvious—for* example, an ulcer of the lip caused by the sharp edge of a tooth. We *also* include several fractures, injuries the nature of which was verified by the aid of the X rays, and a number of hernias. In Class 1 are placed 34 (10·82 per cent.) of the 314 Institute cases, 77 (11·66 *per cent.*) of the 660 private cases, and 111 (11·39 per cent.) of the total 974 cases.

THE USE OF LUMINAL SODIUM IN EPILEPSY.

By J. TYLOR FOX, M.A., M.D., D.P.M.,
MEDICAL SUPERINTENDENT, LINGFIELD EPILEPTIC COLONY.

The history of the drug treatment of epilepsy is not an encouraging one. "There is scarcely a substance in the world," says Sieveking, "capable of passing through the gullet of man, that has not at one time or another enjoyed the reputation of being anti-epileptic," and it may appear rather an impertinence to report upon yet another drug to be eulogised, tested, doubted, and perhaps ultimately discarded like so many of its predecessors. This paper is, indeed, no more than a preliminary note on the use of luminal sodium, and much more extensive trials over long periods are required before the value of the drug can be finally estimated.

Method of Use.

Luminal was first tried in Germany in 1912, and has been fairly widely used, but I have not come across any record of the results obtained from it in England. Luminal is phenylethylmalonylurea, or a derivative of veronal in which one of the ethyl groups is replaced by a phenyl radicle. Luminal sodium is a soluble derivative of luminal, and I have given it in solution, with hot milk or water, in doses of 1 to 2 grains once a day, usually at bedtime. The dosage is small as compared with that of Continental observers, who consider that 3 to 4½ grains can safely be given to adults over prolonged periods, provided that the patients are under adequate supervision. For the purposes of investigation 16 cases of ordinary epilepsy in children or adolescents were chosen; the patients were all liable to major attacks at fairly regular intervals, and none showed signs of marked mental defect or deterioration. It is essential to confine statistical investigation to patients whose fits show a regular incidence, unless very long periods of time are under review. Most of the patients were taking bromide when the luminal was started, and the daily dose, which in no cases exceeded 30 grains, was continued. This course was, no doubt, open to some objection, but had it not been followed, it would have been impossible to say whether any modification of the fit incidence was due to deprivation of bromide or to the luminal sodium. In this connexion it is perhaps worth mentioning that I have known stoppage of bromide to be followed by a considerable lessening in the number of fits. All the patients were under the continuous supervision, both by day and night, of experienced nurses or attendants, so that the fit statistics should be complete. (See table.)

Table showing the Effect of Luminal Sodium upon the Fit Incidence of 16 Young Epileptics.

Initials.	Sex.	Age.	Daily dose of L.S. in grains.	Fit incidence. 6 months prior to commencement of administration.						First 3 months of administration.			Average fit incidence 6 months prior.	Average fit incidence 3 months of admn.	Lb. weight gained or lost.

* Reduced to 1 gr.

Advantages of Luminal Sodium.

Attention may be particularly called to two points in the figures shown. In the first place there is a marked reduction in the fit incidence in every case. This uniformity of reaction to the drug places it, I believe, in a category apart from other anti-epileptic remedies. I have drawn up and published elsewhere similar tables dealing with the effects of belladonna, digitalis, and borax upon epilepsy, and they show no such uniformity of reaction. Borax, indeed, is the only one of the three which appears, when the figures are studied in bulk, to have any effect at all in the reduction of fit incidence. Various statistics of the fit incidence under the influence of bromide have also been published, but I have seen none with beneficial results so uniform as in this table. This point is worth stressing, because it is a matter of common knowledge that marked benefit, or even a complete arrest of fits, may follow the adoption of any new line of treatment, therapeutic or dietetic, or from a chance change in the environment of any individual patient. Secondly, the considerable increase in weight that occurred in almost every case can be no mere coincidence. The average increase of the 16 cases works out at just under 5 lb., and it will be noted that only in one case is a loss of weight recorded.

So much for the advantages of the drug. Are there any drawbacks to its use? Careful observation was made of the mental and physical conditions of all the patients. In no case was complaint made of headache or abdominal pain; nor were there any acute outbursts of excitement such as have been recorded by Continental observers. In 5 of the 16 cases the general mental condition of the patients was apparently unchanged; in 3 the patients were reported as rather more irritable than formerly, while in 4 they were evidently more cheerful and alert. One case, L. C. D., a girl of 15, has become distinctly more dull since taking luminal sodium; her speech is hesitating and she appears to have trouble in finding her words. It is to be noted that her fit record shows less improvement than that of any of the other patients, and that her increase in weight is correspondingly small. Two boys, L. J. H., aged 13, and R. S., aged 11, became sleepy after taking the drug for a few days. In both cases the dose was probably too large, and improvement followed on its reduction. Finally in the fourth month of administration one boy, C. H. C., aged 12, became very dull and lethargic, and could only with difficulty be persuaded to eat his food. The drug was stopped and the boy began to get back to his normal condition some days later; but as he had an exactly similar attack some time ago it does not seem reasonable to ascribe his condition to the luminal sodium.

Best Results in Cases with Major Attacks.

As in the case of other drugs, luminal sodium seems to give best results in cases liable to major epileptic attacks; cases who suffer from momentary losses of consciousness, or from periodic short attacks of altered consciousness with automatism, are notoriously inaccessible to drug treatment. Nevertheless there is recorded a diminution of momentary attacks in three as diseases, has been correct The *diagnosis* is therefore, purely *provisional* In many instances of this class the noxious agent, whatever it may be, appears to have a purely local action, and nature is able to get rid of it without damage, aided perhaps by approximate remedies But we know that these local conditions appear so commonly as symptoms of more generalised disease that we hesitate to treat them lightly, or to judge of their significance without prolonged observation

Bronchitis may be taken as a typical instance We do not include in this class recurrent bronchial catarrhs of children, which suggest some underlying weakness, or the chronic cough of middle and later life which is associated with degenerative changes, but cases are included in which no other signs of disease could be detected at the time of examination We know that attacks may pass off, leave no trace and never recur But everyone has found other symptoms appear at some later date, and has watched the gradual emergence of the typical picture of pulmonary tuberculosis (Fig 9) We have made the secondary diagnosis before the primary diagnosis and in this case the secondary condition was of comparatively trifling importance The diagnosis of acute rheumatism, followed by detection of endocarditis, was of a different order

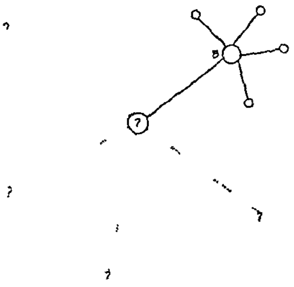

FIG 8 —? represents the noxious agent B represents the local lesion giving rise to a group of symptoms The dotted lines indicate that a watch must be kept for more generalised symptoms

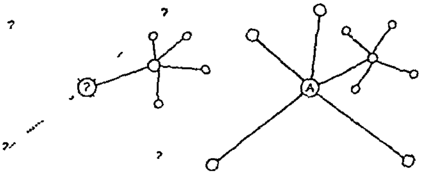

FIG 9 —Showing gradual emergence of the primary diagnosis

It should be noted that when a case assigned to this class alters its picture—except by addition to the group of symptoms explicable by the existence of the local lesion that is to say, when it becomes necessary to fill in any of the dotted lines and queries —it ceases to belong to that class and finds its place in one of the others We have included appendicitis and gastric ulcer, because with our present knowledge it is impossible to determine how far they are symptoms and how far diseases in themselves

In Class 5 are placed 62 (19 74 per cent.) of the 314 Institute cases, 155 (23 48 per cent) of the 660 private cases, and 217 (22 27 per cent) of the total 974 cases The following are examples from the lists

Institute (62 cases)

Appendicitis
Blepharitis
Bronchitis
Colitis
Constipation
Cystitis
Duodenal ulcer
Gastric ulcer
Hæmorrhoids
Intestinal adhesions
Intestinal catarrh—thread worms
Laryngitis
Nephritis
Occipital neuralgia
Pleurisy
Pyelitis
Sciatica

Private (155 cases)

Acne rosacea
Acne vulgaris
Adenoids
Bronchitis
Coccygodynia
Chronic rhinitis
Conjunctivitis
Constipation
Gastric ulcer
Glossitis
Mastitis
Nephritis
Otitis media
Pharyngitis
Phlebitis
Pleurisy
Sciatica
Synovitis
Tonsillitis
Ulcer of auditory meatus

Class 6 (Fig 6) contains the cases showing a number of uncoordinated symptoms with no recognisable common cause Most of our time at the Institute is spent in endeavouring to study such cases In going over the Institute records from the beginning we indexed all the cases under leading symptom ' and 'provisional diagnosis' and endeavoured to divide this undiagnosable class into groups, for example, intestinal toxæmia, neurasthenia, dyspepsia, &c It might be better not to employ such terms at all, as they are apt to give an unconscious bias in favour of one theory over another

Symptoms of toxæmia are very similar in all cases and to search for a correspondence in symptoms among the members of a group formed on no more sure basis than the existence of constipation, or the presence, or suspected presence, of ileal stasis may be a waste of time It would be more satisfactory to form no subdivisions until some definite grouping of symptoms has emerged from a general study of all the cases In Class 6 are placed 132 (42 03 per cent) of the 314 Institute cases, 350 (53 03 per cent) of the 660 private cases, and 482 (49 48 per cent) of the total 974 cases The following are examples from the lists —

Institute (132 cases)

Anæmia with history of tachycardia
Chronic *dyspepsia*
Dyspepsia—palpitation
Exhaustion
Intestinal stasis
Intestinal toxæmia
Gastro intestinal derangement
Malnutrition
Nervous disorder (functional)
Neurasthenia—dyspepsia
Toxæmia of unknown origin
Toxæmia—tachycardia
Toxæmia—toxic angina
Vasomotor instability

Private (350 cases)

Bilious attacks
Cough exhaustion insomnia
Dyspepsia—mental depression
Dyspepsia—palpitation
Exhaustion—abdominal pain
Exhaustion—extensive temporary *staining of skin*
Exhaustion following pyrexia *of unknown origin*
Exhaustion—giddiness
Exhaustion—headache—*dyspnœa*
Exhaustion—*palpitation*—constipation
Fainting attacks
Headache—cough—*exhaustion*
Headache—worry—dyspepsia
Nausea—epigastric tenderness
Menstrual irregularity
Neurasthenia

From this confused class will no doubt emerge in time not only cases of advanced disease the first symptoms of which are already present but not understood, but also cases proving in their progress the relationships of many diseases now regarded as entirely dissociated and even the common origin of many of them The undiagnosable cases are apt to cause despair to the general practitioner, but if they are viewed rightly they present him with an invaluable *field of study—the study of early diseases*—which is really *open to him alone*

Grouping of Cases

We are grouping *all cases seen at the Institute* under the six classes with the *object of noting what transference from one class to another may take* place during observation and treatment

The following tables give the numbers and proportions of cases in the various classes —

	Institute cases (314)		Private cases (660)		Total cases (974)	
Class	No	Per cent	No	Per cent	No	Per cent
1	34	10 82	[illegible]	11 66	111	11 39
2	7	[illegible]	13	[illegible]	20	2 05
3	34	10 82	51	7 72	[illegible]	[illegible]
4	45	14 33	14	2 12	59	6 05
5	[illegible]	19 74	155	23 48	217	[illegible]
6	13	42 03	350	3 03	482	49 48

We accept the cases in the first four classes as diagnosed, those in the last two classes are undiagnosed or undiagnosable We do not desire to place undue value on the diagnosis of a disease as compared with the detection and interpretation of a symptom

The following table shows the proportions of diagnosed cases in the various lists —

	Institute	*Private*	*Total*
Number of cases	314	660	974
Cases diagnosed	120	155	[illegible]
Proportion diagnosed	[illegible]	23 48 %	[illegible]

birth as a routine although too weak to suckle. Immediately after the establishment of lactation on third day breast pump was used and breast milk so withdrawn was given to child by pipette or spoon—a drachm every two hours for first few days—increased gradually in three weeks to six drachms every three hours.

Progress has been uninterrupted, as shown by the marked increase in weight. There has been no vomiting or diarrhœa since birth; stools have always been normal.

Weight.—At birth, 1 lb. 6 oz.; end of first week, not recorded; end of second week, 1 lb. 14 oz.; end of third week, 2 lb. 10 oz.; end of fourth week, 3 lb. ½ oz.

The whole case is interesting in that various authorities, including Budin of Paris, have stated that mortality of premature babies weighing under 3 lb. is 100 per cent., and also as emphasising the importance of breast feeding in premature babies. It is especially in the first few days of lactation that the child derives from mother's milk those immune bodies which are capable of protecting it against infections of all kinds.

A CASE OF

BULLOUS ERUPTION CAUSED BY MAY-WEED.

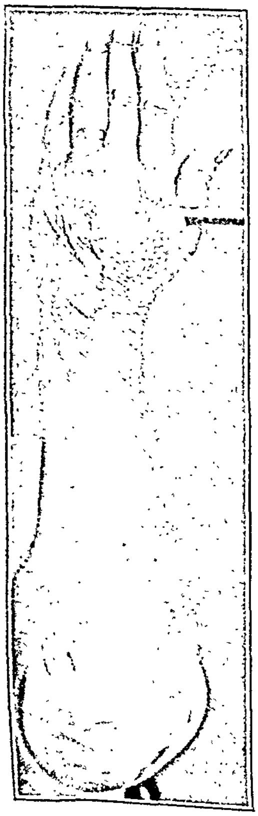
BY J. H. SEQUEIRA, M.D., F.R.C.P. LOND., F.R.C.S. ENG.,

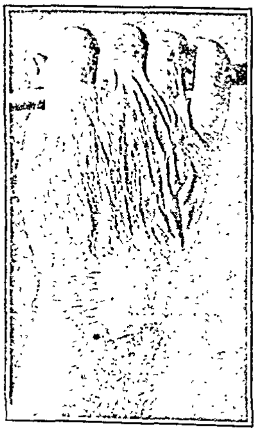
PHYSICIAN, SKIN DEPARTMENT, LONDON HOSPITAL.

THE attention recently called to plant dermatitis and the fact that this is the first case of its type seen in my clinic at the London Hospital has led me to publish this note.

On June 30th, 1921, a married woman, aged 51, presented herself at the Skin Department at the London Hospital with a remarkable eruption of blebs on the left elbow and both wrists. She was a strong, healthy woman, and her face, forearms, and hands were deeply tanned by the sun. She had been engaged in pea-picking in Essex. It was difficult to get exact dates, but apparently the eruption for which she consulted me had come on acutely two or three days before. When examined she had an enormous, irregular, flaccid blister over the left elbow, extending down the back of the forearm for 3½ to 4 inches. A similar bleb, 3 inches in its long diameter and from 1 to 2 inches wide, was present over the ulnar side of the back of the left wrist, and a rather larger bulla over the ulnar aspect of the back of the right wrist. The fluid in the blebs was clear serum and there was no zone of erythema round them (Figs. 1 and 2). The patient complained of pain and some irritation. She ascribed the lesions to poisoning with May-weed, a common field-weed. Abrasions, produced by her occupation of pea-picking, apparently preceded the lesions. She described other cases amongst workers similarly employed, and on inquiry in South Essex I obtained a history of other cases in which individuals had been obliged to give up work for some weeks. Inquiries made for me in Kent elicited the same information.

FIG. 1. FIG. 2.
Showing the bullous eruption (1) on left forearm and hand; (2) on right hand.





The lesions were dressed with a powder of zinc, starch, and calomel and speedily healed.

Remarks.

In Bernhard Smith's work on "Poisonous Plants of All Countries" (p. 73) *Anthemis cotula* (May-weed) is included in the appendix of plants "reputed to be poisonous." In Maisch's "Manual of Materia Medica," seventh edition, p. 260, *Anthemis cotula*, May-weed, wild chamomile, belonging to the natural order Compositæ, Anthemidæ is described as having an unpleasant aromatic odour, bitter acrid taste. Its constituents are a volatile oil, valerianic acid, acrid fat. tannin, anthemidine (?), anthemic acid (crystalline, bitter, soluble in ether). Valerianic acid is classed as an irritant by B. Smith (loc. cit.).

I obtained some fairly fresh plants and rubbed the juice of the leaves and flowers into my forearm, both into the unbroken surface and into a scarified area. In the spots treated with the juice of the leaves a rather tender papule developed the same evening, both in the scarified and unbroken parts. The papules lasted for five days and cleared up, leaving no mark. There was no vesication. The specimen weed had been gathered 12 hours, and it is possible that the plant is more virulent at certain times than others.

A CASE OF

CONGENITAL ABSENCE OF RIGHT PECTORALIS MAJOR.

BY A. G. MILLOTT SEVERN, M.D. BRUX., M.R.C.S., F.C.S.,

PATHOLOGIST, EAST SUSSEX COUNTY MENTAL HOSPITAL.

A POST-MORTEM examination performed at the Royal Sussex County Hospital on a man, aged 44 years, who died from perforated gastric ulcer, showed complete absence of the right pectoralis major, including both the pars sterno-costalis and the pars clavicularis. There was no remnant of muscular tissue or fascial band to be found; the ribs were normal, being covered only by the skin and subcutaneous tissue where the pars sterno-costalis should be; the condition may therefore be assumed to have been congenital. The right pectoralis minor and both the pectoral muscles on the left side were present and well developed, and there was no other muscular deficiency or abnormality of the thorax.

Absence of all or part of the pectoralis major on one or both sides is decidedly rare, but Bing and other anatomists have stated that variations occur more often in the pectoral group than in any other of the skeletal muscles—after allowing that abnormality of the pectorals is more easily detected than is the case with other smaller or less apparent muscles. Developmentally this group of muscles is among the last to be acquired, and therefore one would expect to find in them the most frequent variation. In this case the condition had apparently caused but little disability during life, for the man had followed a laborious occupation; in fact, in most of the recorded cases where pectoral muscle abnormalities were not associated with other deformities, no inconvenience or functional weakness was observed on account of the muscular deficiency—the deltoid and other shoulder muscles sufficing for all the movements of the arm.

These observations tend to show how good a functional result may be expected in a patient whose pectoral muscles have been removed for malignancy.

accepting as "good results" of treatment what has really been a natural staying of the progress of the disease which would have occurred in any case? We have to acknowledge that so far we have discovered no remedy which is specific for tuberculosis in the sense that quinine is specific for malaria and salvarsan for syphilis; and that, in a disease so chronic in its incidence, so capricious in its ebb and flow, such a specific is still to seek.

Uses of Drugs.

But even if this is the case, it is by no means correct to assert, as some have done, that medication plays no useful part in the treatment of pulmonary tuberculosis, a point strongly emphasised by Rénon. The exhibition of certain drugs is of undoubted benefit in many cases; here, too, suggestion plays an even more important part than in most diseases. In this connexion Baudouin quotes some interesting observations of Rénon, which go to show that a comparison of the results obtained by the various methods of treatment in chronic pulmonary tuberculosis displays the same proportion of cases cured or alleviated, cases in which there was no improvement, and cases in which the disease had progressed in spite of treatment. He describes this as "the normal coefficient of amelioration" and enunciates the view that every new method for the treatment of chronic pulmonary tuberculosis, provided that it is harmless, will give satisfactory results. In other words, if the physician himself believes in the remedy, a psycho-therapeutic state is induced, and the medicament is merely the vehicle of suggestion. These remarks, however, must be qualified by the statement that, in my opinion, the abuse of certain drugs has been responsible for a good deal of that dyspepsia which is so often such a distressing feature of the disease. Truly it may be said that the phthisical patient fights for his life "upon his stomach," and that if this is thrown out of gear, his chances of recovery are materially lessened.

Psychotherapy and Organic Disease.

Have we then done all that is possible up to the present for patients suffering from this disease who are placed under our care in sanatoriums or otherwise? I do not think so. I believe we have in psychotherapy a remedy for the alleviation at least of many of the distressing accompaniments of this disease, and one which can materially assist our efforts for the patient's restoration to a moderate degree of health, with arrest of the progress of the disease. It may fairly be asked what part can be played by psychotherapy in an organic disease of this nature. Although Krafft-Ebing and Forel are stated to have carried out certain experiments intended to show that organic changes can be brought about by suggestion, they have had to admit that the results were not very satisfying; it is, I think, also generally acknowledged by psychotherapists that this form of treatment cannot *directly* affect morbid organic changes. But even if this fact is admitted, we should not, I think, strain the law of psycho-physical parallelism by assuming the close co-relation in disease of the psychic factor and the bodily functions—in short, by holding that psychotherapy can in fact react favourably upon the purely physical side of such a disease as pulmonary tuberculosis.

Psychotherapy in its Application to Phthisis.

I propose briefly to mention a few of the conditions for which psychotherapeutic treatment might be advantageously employed in phthisical patients. I have already alluded to the frequent and characteristic reversion to infantile mental reactions which occurs in these patients, in whom re-education of the will—and often restoration of the whole ethical code—is so necessary when in favourable cases the patient is again able to compete in the struggle of life. In some cases again a confusional state exists, with ideas of a persecutory character; while depressive states are by no means rare. The fear of hæmoptysis becomes almost an obsession sometimes, the unhappy patient daily scrutinising the expectoration with painful anxiety. Dyspepsias of a functional character, inability to take certain essential articles of diet, and sometimes insomnia, as well as the control of cough, also come within the scope of treatment by psychotherapeutic means.

In a certain proportion of cases there also exists, as might be expected—more especially in the intelligent and sensitive type of patient—a state of mental conflict which prejudices the treatment and retards recovery. In a few of these cases treatment by psycho-analysis may even be necessary; and I think this treatment can be most suitably carried out at a sanatorium. There are those who say that the sanatorium has outlived its usefulness, and has in many ways proved an expensive fraud; but is this in fact the case? There are certainly grave defects in our sanatorium methods which might be enlarged upon, but I am only here concerned with such defects or deficiencies as bear upon actual treatment.

Necessity of Individual Treatment in Phthisis.

Pulmonary tuberculosis is above all a disease requiring individual treatment, and the inevitable tendency to standardise everything in connexion with the patient in a large sanatorium—the administration of what may be called "massed" treatment—is from every point of view unsatisfactory. Speaking generally, this applies to medication, dietary, and exercise. Occupational therapy has been a step in the right direction from the point of view of re-education on the physical side; but, recalling the law of psycho-physical parallelism, re-education on the mental side for the psychic defects already enumerated is of no less importance. I am firmly of opinion that when a patient is admitted to a sanatorium, in addition to the ordinary medical history of the case, the fullest details of the patient's family and personal *mental* history should be sought. A fuller knowledge of the personality of the patient than is now ordinarily obtained is essential. This having been obtained, such treatment as may be found necessary after due observation, either in the form of mental exercise and relaxation, or more specifically as psychotherapy, and in certain cases psycho-analysis, should be duly instituted. The results obtained at the New Nancy School presided over by Edouard Coué, in which auto-suggestion is more specifically employed and in which a number of cases of pulmonary tuberculosis are included, provide remarkable proofs of the value of psychotherapy in this disease. There is certainly sufficient evidence to warrant a wider and more systematic use of this form of treatment in pulmonary tuberculosis. It is too much to expect that the medical superintendent of a large sanatorium, immersed as he is in the routine duties of his position, can deal with this side of the question even if qualified to do so, which he seldom is. The fact is that for the most part our sanatoriums, judged by the criterion of such an institution as the Loomis Sanatorium in America, are woefully understaffed. In the larger institutions one of the staff should possess the necessary qualifications for psychotherapeutic treatment in addition to his special knowledge of tuberculosis, and in the case of the smaller sanatoriums, such special knowledge on the part of the medical superintendent should be regarded as essential. It is to be assumed, of course, that in every case the physician in charge is himself equipped with the fundamental personal qualities of confidence in himself and his work, a spirit of cheerful optimism and of infinite patience, without which the management of the phthisical patient, always difficult, becomes well-nigh impossible.

By such means those who are able to leave the sanatorium with the disease arrested will again be able to play a part in the life of the community with renewed self-confidence, with will power restored, and with a broader and more optimistic outlook on life; while even those for whom our efforts are unavailing may be enabled to face with fortitude the termination of their sufferings.

affairs. Dante remains with us to tell us how false is such a divorce. Only by bringing the same clearness of soul to politics as to personal relations, only by rooting our politics in a great consciousness of the full value of life, can true peace be attained. How eagerly Dante was concerned with the literary and stylistic problems of his day, how far he was from scorning the humbler problems of language and syntax from the height of his towering majesty of thought, is made apparent by Mr. Gardner's essay on "Dante as Critic." Literary criticism of a most pertinent description is embedded in the "Divine Comedy," while the "Vita Nuova," apart from its anatomical analyses of the lyrical poems incorporated in it, contains a lengthy digression on the poet's licence for personalising abstractions. Dante's importance as a politician is further emphasised in Mr. Wicksteed's essay "Dante and the Latin Poets," wherein the noble name of Virgil is added to the list of pre-eminently political poets, while in Mr. Mackail's "Dante and Virgil" is quoted the verse of Dante which has been most used in political controversy these last days—

> "A Pola presso del Quarnaro
> Che Italia chiude e suoi termini bagna;"

than which denial of the "Italianità" of Fiume the very Serbs could not find a more decisive statement to give lustre to their case.

Mr. A. G. Ferrers-Howell in "Dante and the Troubadours" explains the theories of chivalrous and transcendent love which provided the shell of the "Vita Nuova," and shows to what an extent Dante owed his mastery of the short lyric to the study of the Provencal court poets.

As to the two remaining heads of criticism, the name of the work stands at the head of this review, but the branch of philosophy to which the whole belongs is a problem that would have puzzled Dante himself in the solution—and, for that matter, to what branch of philosophy would he have assigned his own immortal poem, of which this book is the shadow?

THE NEW STONE AGE IN NORTHERN EUROPE.

By JOHN M. TYLER, Professor Emeritus of Biology, Amherst College. London: G. Bell and Sons, Ltd. 1921. Pp. 310. 15*s*.

THE study of early races must always be a fascinating one, and innumerable books have been and continue to be written thereon. Professor Tyler's unassuming work is, as he tells us in his preface, prepared for young students, and is merely to be considered as a good host who introduces "intelligent, thoughtful, and puzzled readers to the company and viewpoint of the pre-historian." Hence the extensive bibliography, which will afford ample food for the student. Prof. Tyler discusses in his first chapter the coming of Man, refers to Pithecanthropus, and states that "we still lack foundations for any hypotheses as to exactly when, where, or how the erect ancestral ape-man emerged into real manhood." Anyway, primitive man appears to have started life in "the whole of the parkland zone curving around the western buttresses of the plateau of Thibet," a region which elsewhere Prof. Tyler calls the Iranian plateau. From this plateau early man migrated to India, to Northern Africa through what are now Mesopotamia, Palestine, and Egypt, through Asia Minor to the Ægean, and westward and north of the Caspian through Southern Russia to the Carpathians. From Africa he also passed into Europe by means of the then existing land bridges at Gibraltar and Sicily—South Italy.

It was at some time during the Glacial Epoch that man first arrived in Europe, when the ice sheet extended roughly as far as lat. 50° N. Then began the Eolithic Period, which was followed by the Early and Late Palæolithic Periods; the Eolithic and Palæolithic Periods correspond roughly to the Pleistocene Period of Geology. In succession followed the Neolithic Period, with which Prof. Tyler's book deals, but it was during the Late Palæolithic Period that that wonderful race, the Cro-Magnon people lived. The discovery of skeletons in 1868 of this race gave a check to the Darwinian theory that man got progressively more ape-like as one went further back in time, for the skeletons discovered were those of tall men from 5 ft. 11 in. to over 6 ft. That of the one woman, who was young, measured 5 ft. 3 in. The artistic powers of man were developed already, as is evident by the drawings in the cave dwellings of Southern France and the Pyrenees; but this brilliant race died out, and the Neolithic people succeeded them. These lived at the time when the ice sheet had retreated, for their remains are found in the shell heaps of places in Europe as far north as Denmark. Prof. Tyler gives a very readable account of Neolithic man and his ways, his habitations, his industries, and his migrations, concluding with a chapter on the Indo-Europeans, whose culture and life, he says, were a product of Neolithic experience and a blossoming of Neolithic growth. The book is a useful introduction to a very complicated study, and we would add one work to Prof. Tyler's bibliography, namely, Prof. Lionel Lyde's "Continent of Europe," especially the first ten chapters thereof.

CHEMISTRY.

The Chemistry of Enzyme Actions.

By K. G. FALK. New York: The Chemical Catalogue Company. 1921. Pp. 136.

THE publication of this volume marks an interesting departure in the literary activity of the American Chemical Society, its essential object being the development of a chemical literature in the English language without regard to the usual commercial considerations of book publishing. By an arrangement with the Inter-Allied Conference of Pure and Applied Chemistry in 1919, the society undertook the production and publication of scientific and technological monographs on chemical subjects. At the same time the American Physical Society became responsible for the publication of critical tables of chemical and physical constants. The object of these monographs is to present the knowledge available upon the chosen topic in a readable form intelligible to those whose activities may be along a wholly different line. A second purpose is to promote research in the branch of science covered by the monograph by furnishing a careful survey of the progress already made in that field and by pointing out directions in which investigation needs to be extended.

The author deals with his subject under the following heads: Velocities of Chemical Reaction—General Theory of Chemical Reactions; Catalysis; Chemical Reactions Catalysed by Enzymes, Physical and Chemical Properties common to Enzyme Preparations, Chemical Nature of Certain Enzymes, Mechanism of Enzyme Actions, Uses and Applications of Enzymes; Present Status of Enzyme Problem. To cover so wide a field in one small volume is an ambitious effort, and Dr. Falk has done a service to his brother chemists in coördinating the existing knowledge and presenting it in so readable a form. The last two chapters especially are of quite exceptional interest.

The Chemistry of Synthetic Drugs.

Third edition. By PERCY MAY, D.Sc., F.I.C. London: Longmans, Green and Co. 1921. Pp. 248. 12*s*. 6*d*.

THE author's object is to give an account of the main facts concerning the chemical nature of synthetic drugs and the principles guiding their production. New drugs are constantly being put on the market and whilst many of them are well known and widely used their chemical nature is often unknown. Before 1914 the manufacture of synthetic drugs was practically confined to Germany, but since then considerable progress has been made in this country. We hope a further impetus will be given when the Safeguarding of Industries Bill materialises; possibly, then, in the course of a few years we may possess something approaching the highly organised German organic chemical industry.

of the patients in the table who were liable to them; and one of the most satisfactory cases we have had is that of a boy aged 9 who was liable to very frequent psychic attacks with automatic movements, the number and duration of whose attacks have been very greatly diminished by three months of luminal treatment, and who has become, as a consequence, very much brighter mentally.

The modern view of the psycho-genetic origin of epilepsy has led some writers to discount the value of any treatment directed to reducing the fit incidence or arresting the fits. Fits are said to be protective reactions away from an environment to which the epileptic, with his egocentric sensitive temperament, cannot adapt himself, and to stop fits is to court further mental trouble. I have seen mental disturbance follow the sudden cessation of fits in an old-standing case of epilepsy, but more commonly the patient becomes more alert and cheerful when his fits stop, and I have no fear that in using a drug that will arrest fits we are doing the patient any disservice, provided that we are satisfied that the drug itself has no prejudicial effect upon him. It is, of course, not claimed that luminal sodium, or any other drug, has any curative effect upon the disease; at best it only arrests or lessens the frequency of the convulsive attacks.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

PURULENT PERICARDITIS SIMULATING ANGINA PECTORIS.

BY M. A. CASSIDY, M.D. CANTAB., F.R.C.P. LOND.,
R. O MOON, M.D. OXON., F.R.C.P. LOND.,
AND
F. LE Q. PELLY, M.B., B.CH. ABERD.

THE following case presented such difficulty in diagnosis that it seems worthy of record.

K. D., aged 42, a caterer by occupation, a hearty eater, but not addicted to alcoholic excess, and a very heavy cigarette smoker, had three separate attacks of gonorrhœa during the last two years; apart from this he had been in robust health till May 18th, when he was seen to be standing still, looking very white, and perspiring freely. He was assisted to his room, where he collapsed on the floor. Dr. Pelly arrived shortly afterwards and found him in an almost moribund condition. His face was ashy and sweating; no pulse could be felt, the heart sounds were barely audible, respiration was rapid and laboured; when the patient was able to speak he complained of agonising præcordial pain. There was very little change in his condition half-an-hour later when Dr. Cassidy saw him. The heart sounds were still heard with difficulty, and the pulse could not be felt; the heart was apparently beating feebly and irregularly at a rate of about 50. Strychnine and camphor were injected, with but little improvement, but there was prompt response to amyl nitrite, several capsules of which were administered. After this the pulse improved in volume and became regular, and the pain, which the patient was now able to describe as radiating down both arms, with greater severity in the left arm, diminished in intensity. ¼ gr. morphia and 1/100 gr. atropine were now administered hypodermically with further improvement. During the night he vomited freely, and again complained of severe præcordial pain, but next morning improved sufficiently to be moved into a nursing home. On the 20th he had a fairly comfortable day, but in the evening his temperature rose to 99·8°F. On the 21st he had two syncopal attacks, one associated with angina-like pain. When seen by Drs. Moon, Cassidy, and Pelly in consultation on the evening of the 21st the temperature was 100·4°, pulse 80, respirations 30; the radial artery was much thickened and the tension high. No increase of cardiac dullness could be made out, and the heart sounds appeared to be normal, though earlier in the day Dr. Pelly had heard pericardial friction. There was a little dullness and quiet breathing, with nasal voice sounds, at the extreme base of the right lung. He still complained of slight præcordial pain, but appeared to be in no great distress, could talk quite freely, and was able to sit up in bed for examination. At 11 P.M. that evening there was a sudden fatal syncope.

At the autopsy on the following day the pericardium was found to contain about 2 oz. hæmorrhagic sero-purulent fluid, and both the parietal and visceral pericardium were covered with punctate hæmorrhages and patches of lymph. The valves of the heart appeared to be perfectly normal, but there was well-marked recent atheroma of the aorta just above the aortic valves. The right lower lobe of the lung was congested and collapsed, but no other signs of organic disease were discovered. Unfortunately, no bacteriological examination was possible.

Remarks.

In this case the onset was typical of severe angina pectoris, and the subsequent syncopal attacks, one with pain, also seemed to support this diagnosis. In view of the condition of the root of the aorta it seems probable that he was in fact killed by angina pectoris, though this condition was excited by an unrecognised pericarditis. The pyrexia, furred tongue, and transient friction, coupled with basal pulmonary collapse (due, no doubt, to diaphragmatic arrest), should have led us to the correct diagnosis. In the absence of any other septic focus, it seems probable that the pericarditis was due to gonococcal infection.

NOTE ON EARLY PROGRESS OF AN INFANT OF ABNORMALLY SMALL WEIGHT.

BY F. CHURCHILL DAVIDSON, M.B., CH.B. EDIN.,
D.P.H. OXON.

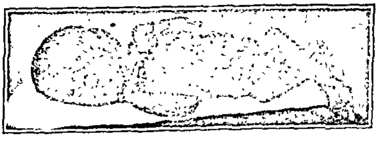
THE following case is of interest in that the infant weighed only 22 oz. at birth.

Mrs. X., a multipara, aged 34, who had been married ten years, gave birth on July 4th, 1921, to a male child weighing 1 lb. 6 oz. Calculating from the date of the last menstrual period, period of gestation was 31 weeks; but taking into consideration both the possible margin of error of 3 weeks—corresponding to the length of menstrual interval—and the appearances of the child at birth, this gestation period appears to have been over-estimated, and it is most probable that the period was only 32 weeks.

Previous history.—1. Miscarriage at third month in 1911. 2. A female child was born Feb. 10th, 1920, and lived for three days. Cause of death stated to have been "prematurity" (7 months). Both parents are apparently healthy.

Present history.—Labour was uncomplicated and completed in five and a half hours; normal head presentation.

Condition of child at birth. The weight was 1 lb. 6 oz., and the length 15 in. The arms and legs were nearly equal in length; umbilicus was situated close above pubis; sex characters (male) were fully developed; skin was wrinkled and of bright flesh colour; eyebrows and eyelashes were developed and eyelids opened occasionally; there was dark hair on head and downy hair on body. The following herniæ were present: slight umbilical hernia, R. inguinal hernia, large L. scrotal hernia (latter reducible and retained by wool truss). Phimosis was also present and dorsal incision was made on July 12th.



Photograph of child taken at end of fourth week.

Treatment.—The child was immediately covered with warm olive oil, wrapped in cotton-wool and placed in oven at temperature of 90°F. until extemporised incubator was prepared. This latter consisted of a wicker basket with three hot-water bottles placed round the child. A temperature of 85° was maintained, as recorded by bath thermometer placed between blankets beside child and checked from time to time. Hot bottles were refilled alternately.

Feeding.—For the first 18 hours the child was fed hourly with small quantities of a whey and cream mixture (3 oz. in 24 hours) and on third day feeding with breast milk was commenced. The child was laid to breast at feed times from

Psycho-Analysis.

Addresses on Psycho-Analysis. By J. J. Putnam, M.D., Emeritus Professor of Neurology, Harvard University. International Psycho-Analytical Press: George Allen and Unwin, Ltd. 1921. Pp. 470. 12*s.* 6*d.*

Dr. Putnam's leading position amongst American neurologists when, at the age of 66, he accepted the theory of psycho-analysis gives value to his writings on the subject, and this posthumous collection of essays has an intrinsic value of its own. Many of them are controversial, but kindly and persuasive, and throughout there appears not merely a desire for what he regarded as scientific truth, but for the happiness and well-being of his patients; sympathy and human understanding have plainly influenced his attitude, and the reader feels that Dr. Putnam's effort to convince his colleagues arose first of all from his belief that the treatment and cure of the neurotic sufferer demand the application of the principles he so vigorously advocated. Yet there is no attempt to shirk the fight; taking into account Dr. Putnam's age and position at the time, we must, whether we think him right or wrong, admit his courage when he wrote:—

> "If our spiritual life is good for anything it can afford to see the truth. No investigation is wrong if it is earnest. Knowledge knows nothing as essentially and invariably dirty. It is a piece of narrow intolerance, cruel in its outcome, to raise the cry of 'introspection' in order to prevent an unfortunate invalid, whose every moment is already spent in introspection of the worst sort, forced upon him by the bigotry, however well meant, of social conventions, from searching, even to the death, the causes of his misery, and learning to substitute the freedom, liberality, tolerance, and purity that comes from knowledge for the tyranny of ignorance and prejudice" (p. 18).

He comes out to meet his opponents in his address on "Comments on Sex Issues from the Freudian Standpoint." He speaks of the opposition as "a needless prejudice which a temperate reconsideration of the facts and arguments should remove," and bases his advocacy both upon scientific regard for truth and upon the needs of the patient.

> "One must be able to look squarely and without loathing at the facts, or one must say farewell to honest judgment. But no sooner do I ask for this fairness than I am forced to grant that it is hard to give. The details of that portion of one's life which has to do directly or indirectly with the function of reproduction are usually guarded either as something too sacred or too unpleasant to be talked about. And the worst part of the business is that the persons whose interests are most at stake—namely, the neuropathic patients—must inevitably, in the present state of public opinion and public ignorance, pass through a period of severe self-humiliation if they consent to lift the veil from their own memories, or to study the psychological mysteries of their own childhood" (pp. 132–133).

Controversy apart, the author's exposition of principles is aided by long experience of older methods of treatment, and he is able to point to the personal histories obtained from patients by analytical methods as being immensely different, both in detail and completeness, from those obtained before the new treatment was begun. His frank reference to his own resistance against accepting the new theory, and his comparison of results before and after his change of view, form a record which is not likely to be repeated. Although there is no attempt to instruct in the technique of analysis, yet his clinical accounts of cases show the utility of treatment and the way in which the whole previous life of the patient may be involved in the production of the psychoneurotic symptom. Psycho-analysts might regard his analyses as superficial, but this superficiality is no disadvantage to the general reader, who may be unacquainted with the more intricate theories of recent workers; it is remarkable that Dr. Putnam has, seemingly without effort, almost entirely avoided technical phraseology.

It would be a disappointment if we found that Dr. Putnam had given us nothing in the way of criticism of psycho-analysis. In "The Necessity for Metaphysics" he pleads for an extension of the field of psycho-analysis beyond the empirical acceptation of its own findings, so that the ethical motives which indicate man's higher destiny should find consideration; in his last address he returns again to this advocacy, when he quotes Freud's view that not moral estimates but knowledge was needed for solving the problem of human life and motives, and he regards this view as a testimony both to the strength and the weakness of the psycho-analytic movement.

The absence of direct relation between the different addresses, which are in chronological order, enables the book to be read during spare moments, and it is the kind of book to which the reader returns with pleasure. Whoever reads it will, whether he accepts the psycho-analytical view or not, realise that the current methods of attack upon psycho-analysis are of no avail against Dr. Putnam's presentation. A biographical notice by Dr. Ernest Jones gives personal reminiscences of Dr. Putnam, and a lengthy bibliography indicates his contributions to psychological literature.

Concept of Repression. By Girindrashekar Bose, D.Sc. Cal., M.B. Cal., Lecturer in Psychoanalysis and Abnormal Psychology, and Examiner in Experimental Psychology and Physiology, Calcutta University. Calcutta: Sri Gouranga Press. 1921. Pp. 223.

Dr. Bose in his preface speaks of his difficulties in the study of psycho-analysis, and of the fact that truths he found for himself turned out to be already widely known. He has presented these truths in his own way, largely by means of analogy and diagram, and their relation to the conceptions of psychoanalysis, as ordinarily expressed, can easily be seen; for instance, his diagram on p. 49, showing the alliance of two wishes to obtain expression by symbolism, gives an example of what is generally called over-determination. His explanations are not easy to follow, and the absence of clinical illustrations has just the effect that he anticipates in his preface; one feels that his theories are mere speculative products. His chief contribution to theory is the view that the development of any particular wish is always accompanied by a development of a wish of the opposite type; this is an advance upon the theory of ambivalency, by which a complex is regarded as possessed of two opposing tendencies—for example, sadism and masochism—but the view is dogmatically stated, and supported only by unconvincing analogies, so that proper criticism of it is impossible.

We feel that Dr. Bose's ability would be more fruitfully employed in giving records of his work in a sphere where social and family conditions are so different from those where clinical psycho-analysis has hitherto been carried on. His few remarks on the male attitude to the purdah system indicate that he can throw light upon the unconscious motive of people whose mode of life is different from ours.

Psycho-Analysis, Sleep and Dreams. By André Tridon. London: Kegan Paul, Trench, Trübner and Co. 1921. Pp. 161. 7*s.* 6*d.*

The medical reader may judge Mr. Tridon's book by his handling of "sleeping sickness," a title under which he groups trypanosomiasis, hysterical narcolepsy, and encephalitis lethargica, saying of the first-named that "imitation easily spreads the contagion, and this is probably the reason why entire villages are decimated by that curious malady." His statements that memories of recent experiences accumulate in our autonomic nerves (p. 43), and that the anxiety day-dream fills the body "with glycogen and a sense of power" (p. 114) show a similar rash dogmatism. On p. 28 he assumes that all neurotic complaints are transmitted through imitation. If this be true it destroys the whole psycho-analytic theory, and Mr. Tridon's assumption warns the reader that his views on psycho-analysis are to be

Reviews and Notices of Books.

SURGICAL THERAPEUTICS AND OPERATIVE TECHNIQUE

By E DOYEN English edition prepared by the Author in collaboration with H SPENCER BROWNE Vol III Operations on the Abdomen London Baillière, Tindall and Cox 1920 With 959 illustrations Pp 811 45s

THIS is the last volume of a great work. Doyen was a surgical genius, some of whose characteristics did not make for popularity amongst his professional brethren but no one can deny that he contributed largely to the advance of surgery by his inventive ingenuity, boldness and skill. He placed his stamp upon everything that he touched. Originality of method frequently and justly claimed in this volume for its author, has its drawbacks in that a method good in itself may be used on occasions when classical technique would be preferable. For example, the method of crushing pedicles was largely perfected by Doyen but to recommend the use of an écraseur to crush the prepuce prior to its removal in a simple circumcision is surely to ride a hobby a little too far.

The first half of the volume deals with operations on the abdominal wall the liver peritoneum, stomach and intestines, the second half treats of genito urinary operations in both male and female. The section on the stomach and intestines is by far the best, though the author gives a very meagre description of certain conditions, notably the hour glass stomach. The illustrations of the various forms of anastomosis are plentiful and clear. The section on liver and gall bladder is not so good. For example in connexion with liver abscess, we find the dogmatic assertion All punctures, even of an exploratory nature are dangerous whilst treatment of a liver abscess by aspiration is not even mentioned. Again Doyen recommends that where possible the gall bladder should be removed extra peritoneally by subserous decortication, a procedure which is either impossible or unnecessary if drainage be provided. In view of the usual instructions for performing cholecystostomy it is strange to find an illustration showing the mucous membrane of the gall bladder stitched to the skin (Fig 120). The section on genito urinary surgery in the male is less adequate than that dealing with the female. The only operation described for hydrocele is that of inversion of the sac. For ectopia vesicæ the method of reconstruction of the bladder by skin flaps is described and illustrated whilst the transplantation of the trigone and ureters into the sigmoid or rectum receives no mention. Concerning hypertrophy of the prostate the author states I prefer to total prostatectomy the removal of abnormal prostatic fibromata by the suprapubic route preserving the rest of the gland and wounding the urethra as little as possible. The section on pelvic peritonitis in the male is very interesting. Since the name of Doyen has for many years been better known in connexion with female genito urinary surgery than with any other branch, it is not surprising to find a long section devoted to this subject. The translator reminds us that here is much that is of historical interest. He might almost have added and only of historical interest" for the vaginal route has of late years been almost superseded by the abdominal route for dealing with most female pelvic disorders.

Taking the book as a whole it is an interesting and informative exposition of the methods adopted in abdominal surgery by one of the masters in technique though the sections are unequal in value and in some cases do not represent the best modern teaching. The illustrations excellent though they are, are almost too numerous. There are 11 nearly full page illustrations showing the suture of the abdominal wall after the sac of a hernia has been tied. To show the passage of the first deep suture the passage of the second deep suture, the first two sutures ready to be tied, and the first two sutures tied, as four separate and large illustrations improperly assumes a poverty of intellect and wealth of purse in the purchaser of a book on surgery.

We have nothing but praise for the translator, who has used clear and where desirable idiomatic English, while preserving the sense of the original.

DANTE ESSAYS IN COMMEMORATION 1321–1921

University of London Press 1921 Pp 25[illegible] 12s 6d

Dante, writing to Can Grande we learn from Mr Edmund Gardner's contribution to this book stated that the heads under which criticism of a book should be ranged are as follows subject agent form end, title of work and branch of philosophy. Dante's own classification may well be turned to account here. The ' subject is Dante the man and the writer treated from widely differing points of view as poet, critic politician philosopher, and lover and shown in relation to his own time our time and eternity. The agents are thirteen distinguished students of Dante, three Italian and ten English. The exterior form of the book is admirable its printing and illustrations (photographs of William Blake's and Botticelli's illustrations to Dante and a facsimile page of a fourteenth century manuscript) being of a quality rarely met with. As to its internal form, it is necessarily somewhat confused owing to the widely differing nature of the contributions which include fragments of translations notes on points of scholarly interest, excerpts from published books, and essays dealing generally with Dante's work or with particular aspects. The end of the publication is the celebration of the sexcentenary of Dante which is this year being observed in Italy and all civilised countries.

The title page bears the sub heading 1321 1921 but not many of the contributors have drawn their inspiration from the idea of the permanency of Dante's value or of its special application to present circumstances. Lord Bryce however, does attempt this and in a most interesting essay called Some Thoughts on Dante in Relation to Our Own Time discovers analogies between that distant age and our own. One was and the other is a period of disillusionment. The nobler souls of the thirteenth century felt bitterly the failure of the various attempts that had been set afoot to base the policy of Emperor and Pope, the two arms of Holy Church on a higher ground than that of mere interest. They had seen the great ideas that had animated S Francis and S Dominic and the metaphysicians of Bologna exert only a limited influence and fail to secure that rebirth of conscience and divine charity by which alone a better state of things could be compassed. In 1921 those who looked to the war to end war as a means of elevating world politics to a less debased sphere of action must feel a similar bitterness but Dante shines down through the ages with the message that hope and reason must finally triumph against unfaith and stupidity.

Signor Benedetto Croce's contribution is an excerpt from his recently published work La Poesia di Dante shortly to be published in English translation it is here printed in Italian. This chapter really needs the context of the whole book to be properly intelligible. Signor Croce emphasises the unity of spirit underlying the work of Dante he was a man who brought to politics to love to literature and to religion the same robust personality informed by the same cosmic doctrines and vigorously realising itself without loss of sincerity in any in all of these branches at the same time. How difficult one must reflect would it be to-day to evolve a standard or set of standards equally applicable to politics and to the life of the soul. In such an age as ours those who give themselves to politics succeed generally because they have no life of the soul while those who value an unsullied conscience keep well clear of the world's east. The French suffered about equally, and the Bulgarians had at one time 23,000 malaria cases in hospital.—Dr. W. Wallace completes his long and valuable discussion of "The Vision of the Soldier." He would like to see peep-sights fitted to the rifle for use at short ranges to allow ametropes to shoot at these ranges without spectacles; peep-sights are fitted for the long ranges. He wonders why head-masters at public schools do not have their boys' teeth and eyesight examined carefully, that defects may be put in order before military service is due or professional work begins. One of the great problems of a national army is the use that can be made of a man with defective vision. He must not be thrown aside. Where can he best be placed?—Captain T. O. Thompson relates the history of an officer who during the war began to suffer from pain about the kidneys, and became cachectic, so remaining for some years, in the course of which he was treated unsuccessfully with an autogenous vaccine of, it was stated, *B. coli* from his urine. When he again came under treatment in India another autogenous vaccine was prepared from his urine plated on Conradi plates. A pure culture of *Bacillus coscorobæ* was found, and he got 3,100,000 as a first dose. This set up a violent reaction lasting four days: temperature up to 105° F., intense pain and tenderness about the kidneys, and extreme bladder irritability; but patient thereafter felt much better. In about a fortnight he got a second injection, 400,000 only this time; a very slight reaction followed. Thereafter dosage was increased by a half each time. He became robust, put on fat, and considered himself cured. No mention of another case of coscoroba bacilluria could be found in the literature.

Parasitology. Edited by G. H. F. Nuttall, F.R.S. Vol. XIII., No. 3. June, 1921. C. F. Clay: Cambridge University Press. 15*s.* net; yearly subscription £2 5*s.*—This number opens with an article on the Life-history of *Helicosporidium parasiticum*, n.g., n.sp., a new type of protist parasitic in the larva of *Dasyhelea obscura* Winn. (Diptera, Ceratopogonidæ) and in some other Arthropods, by D. Keilin. It deals with a protist which differs markedly from all known protozoa and which is highly pathogenic to the larvæ of at least two species of Diptera (one being a fairly common midge) and to a mite. The hosts inhabit wounds in elm and horse-chestnut trees. The striking character of this new parasite is the spore containing three sporozoites and a spiral filament. In the dead body of the host the spores open and the spiral filament unrolls, liberating thus the sporozoites.—The article on the External Anatomy of the *Sarcoptes* of the Horse, by P. A. Buxton, contains an exhaustive morphological description of all the stages of *Sarcoptes scabiei*, var. *equi*, which is very similar to the human *Sarcoptes.*—In the paper on *Sarcoptes* of Man, P. A. Buxton compares *Sarcoptes scabiei* var. *equi* of the horse and *Sarcoptes scabiei* var. *hominis* of man, and concludes that it is at present impossible to separate these two species. In the same article he deals also with *Sarcoptes scabiei crustosæ*, which is the cause of a rare disease known as Norwegian itch, or crusted scabies.—In the Notes on *Rickettsia*, E. Hindle confirms the main observations of Arkwright and Bacot, who showed the association of *Rickettsia* with trench-fever. This micro-organism is only 0·3μ in diameter, it multiplies in the gut of the louse, and the infection of man takes place when the excreta of infected lice touch any abrasion in the skin of a healthy person. The paper contains a description of *Rickettsia* from other blood-sucking and not blood-sucking insects.—The article on the Anatomy and Biology of the parasitic *Aphelenchi*, by F. H. Stewart, deals with three species of nematodes parasitic in plants. In addition to the morphology, the paper contains an account of the life-history of these parasites, indications on the treatment of diseased plants and of prophylactic measures against spread of the disease.—A Supplementary Account of the Dipterous Larvæ feeding upon Molluscs, by D. Keilin, completes a previous list (*Parasitology*, Vol. XI.) of parasitic, [illegible] and saprophytic dipterous larvæ feeding upon molluscs.—The number is concluded with an article on the Nephrocytes of *Pediculus Humanus*, by G. H. F. Nuttall and D. Keilin, which deals with special cell aggregates disseminated in the body cavity of the louse, the function of which was unknown. The excretory function of these cells was demonstrated by a special method of injection of ammonia carmine into the body cavity of lice.—The number contains three portraits obtainable separately of: *Francesco Redi* (1626–1697), *Carolus Linnæus* (1707–1778), and *Carl De Geer* (1720–1778).

New Inventions.

A NEW TRACHEOTOMY TUBE AND FALSE MEMBRANE FORCEPS.

I have designed the tracheotomy tube here illustrated (Fig. 1) with the objects of facilitating cleaning and of preventing the pilot from stopping the child's breathing. Retention of the tube is also facilitated in the case of patients with fat necks.

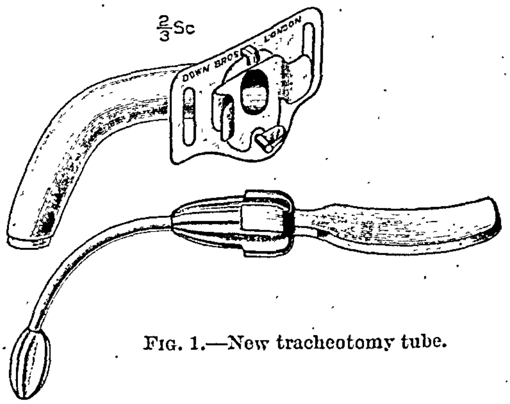


Fig. 1.—New tracheotomy tube.

Compared with the old form of Parker's tube, in the improved instrument the shield is made of stronger gauge silver and quite smooth except for the hook which retains the outer tube. and it has holes only for the outer tube and tapes. The outer tube has a small notch at one side near the front; the tube can be turned round, and as the hook passes through the notch the tube can be removed and properly cleaned. The catch in front of the outer tube, which turns and retains the inner tube, has always been a weak point in the Parker's tube; it was liable to become loose and sometimes came out. The catch is now strengthened. The inner tube is slightly longer to fit the outer tube and has no raised wire loops; these were only necessary on the Parker's tube in order to take the tube out; on my new tube the edges of flange on either side are extended and turn up, and are much easier to clean than the loops. The new pilot has the section of an X, and so leaves four spaces round it, allowing the child to breathe quite easily whilst it is being introduced.

The trachea forceps, which was designed by my late superintendent, Dr. J. McCombie, for withdrawing membrane or inspissated mucus, has been found too thick for going down the trachea of a small child. I have had the instrument made much thinner, as is shown in Fig. 2, and the joint brought nearer the handles. This prevents the blades from locking when in the trachea.

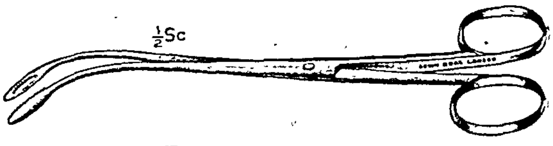

Fig. 2.—Trachea forceps.

Messrs. Down Bros., St. Thomas's-street, S.E., are the manufacturers of the instruments.

A. Cubley, M.R.C.S., L.R.C.P. Lond.
North-Eastern Hospital, Tottenham.

Dr. May's book will be read with interest both by the medical man and the chemical manufacturer; to the former will appeal the chapters dealing with the theory of the action of synthetic drugs, the chemical changes of drugs in the organism, narcotics and general anæsthetics, antiseptics, &c., and to the latter the method of preparation of the different substances. Many references to current and patent literature are included. The author is to be congratulated on having produced a most useful and up-to-date work. It appears at an opportune time and it should be of particular service to those manufacturers of fine chemicals who contemplate extending their activities to meet the home demand for synthetic drugs.

The New Methods of Blood and Urine Chemistry. Second edition. By R. B. H. GRADWOHL, M.D., and A. J. BLAIVAS. London: Henry Kimpton. 1920. Pp. 418. 30s.

THE authors state that they have collected much of the information which has appeared in the journals (mostly American) during the past three or four years. In most cases they have given one method for each test, that one being in their experience the most satisfactory for routine and research work. This frank admission of limitation rather disarms criticism. Otherwise the reviewer would be tempted to draw attention to the omission of many methods which are in common use in European laboratories. The volume is divided into three parts: Technic of Blood Chemistry, Chemical Analysis of Urine, Blood Findings and their Interpretation. It is profusely illustrated and full working details are given of the different tests. A perusal of the book leads to the conclusion that it will be more useful to the medical and chemical specialist on blood and urine than to the general practitioner or student.

AIDS TO OPERATIVE SURGERY.

By H. C. ORRIN, O.B.E., F.R.C.S. Edin. London: Baillière, Tindall and Cox. 1921. Pp. viii. + 236. 6s.

THE teaching of operative surgery can hardly be approached in any other way than by practical demonstrations or by well-illustrated and full printed descriptions. Prolonged experience in teaching and operating, and a natural aptitude for detecting the most essential points in an operation, are necessary preliminaries for the production of an unillustrated synopsis of such a subject. We cannot say that Mr. Orrin has completely succeeded in his task, but he has at least made a praiseworthy attempt to present a succinct epitome of the subject. He is wise in stating "that in no possible way can this little volume be used as a substitute for the classical text-books on the subject."

There are many points which might be modified in any future edition. Very few umbilical herniæ can be dealt with by an incision three inches long. It is certainly not the usual custom to irrigate the bladder with hot water during the enucleation of a prostate; the irrigation is reserved till the enucleation is complete. The Alexander-Adams operation for shortening the round ligaments is neither the only nor the best operation for the cure of retroflexion of the uterus. Halstead's method of approach to the pituitary body by turning upwards the nose is now out of date. Cushing's approach by submucous resection of the nasal septum or Frazier's operation by frontal bone-flap are the alternatives which should be described. War experience has shown the superiority of the frontal skin-flap for restoring the nose. Syme's operation provides no epithelial lining for the nose, which consequently shrinks. The injunction to "render the foot avascular" is impossible to fulfil, though one can easily make the foot bloodless by applying a tourniquet.

The book is well printed, can easily be slipped into the pocket, and should prove useful to the student revising his work after a course of operative surgery.

X RAY DIAGNOSIS.

Die Röntgendiagnostik der Inneren Erkrankungen. By Dr. HERBERT ASSMAN, Professor of Medicine, Leipzig. Leipzig: F. C. W. Vogel. 1921. Pp. 693. M.330.

THE general trend and development of X ray diagnosis in Germany since 1914, as exemplified in Dr. Assman's book, is instructive. The most striking developments would appear to have taken place in the investigation of diseases of the thorax, especially the heart, great vessels, and mediastinum. An outstanding feature of the volume is the free use of excellent reproductions of radiographs in collotype where the finest discrimination is needed, half-tone blocks for others, lucid diagrams, and side-by-side anatomical illustrations where they would help to make the subject more clear. Almost the whole of the book is devoted to the examination of the trunk and head, disorders of the skeleton and limbs occupying less than a hundred pages at the end. Dr. Assman's book is a highly valuable work on the subject of X ray diagnosis; the volume is rather insecurely put together in a paper cover, and its contents deserve a better binding.

A MANUAL OF BACTERIOLOGY, CLINICAL AND APPLIED.

Seventh edition. By R. TANNER HEWLETT, M.D., F.R.C.P., D.P.H. Lond., F.R.M.S., Professor of Bacteriology in the University of London. London: J. and A. Churchill. 1921. Pp. 808. 21s.

THIS work has long ranked among the best of the students' text-books on bacteriology, and the careful revision to which the seventh edition has been subjected ensures that its popularity will be maintained. Several of the chapters have been rewritten and modern work of proved importance has been adequately noticed. In the section on the standardisation of media the question of hydrogen-ion concentration is very clearly described; the chapter on the microscope has been rewritten and the methods of dark-ground illumination are dealt with; the technique of the Wassermann reaction is treated of at some length, the method of McIntosh-Fildes being the one described; and the various modern serological reactions have been incorporated in the appropriate sections. The book is carefully written, well illustrated, and reveals a sense of relative values, all going to make it one of the most readable and convenient of the text-books in this subject.

HUMAN EMBRYOLOGY AND MORPHOLOGY.

Fourth edition. By ARTHUR KEITH, M.D., F.R.S., LL.D., F.R.C.S. London: Edward Arnold. 1921. Pp. 491. 30s.

EIGHT years have elapsed since the last issue of this book, and we rejoice that Sir Arthur Keith has had the inclination and has found the time to bring the present edition up to date. A work by an author of such repute does not call for any criticism when it reaches its fourth edition, and we need only direct attention to certain points about this new issue. It contains 28 chapters compared with 22 in the third edition, and has been brought quite up to date, some parts being rewritten to a large extent. Full justice has been rendered to English writers and investigators, who are not handicapped by their nationality in this book. Mall's estimation of age of embryos is adopted. The account of early embryonic conditions has been extended, particularly from the comparative standpoint, and recent work of Elliot Smith and others has been incorporated in the description of central nervous development. Stress is laid on the developmental details from the evolutionary point of view, and the relation between structure and function is continually shown. The volume is larger, and some 80 new illustrations appear in it. The popularity and success of the previous editions will certainly be extended to this, which ought to be in the hands of every advanced English student of anatomy.

The Pathology of War Nephritis.

DEATH in the first fortnight of acute glomerulo-tubular nephritis is not common, and, as seen in civil practice, acute nephritis is often a complication of some other disease such as scarlet fever or tonsillitis. There has not, therefore, been abundant material for the study of the early histological changes in acute nephritis. The war has made good this deficiency through the epidemic of war nephritis that was observed in the armies in the field; and this disease, which is in all respects a true glomerulo-tubular nephritis, has been particularly convenient for study, since it is at the same time a primary nephritis and a single clinical entity; the cases also were so numerous that it could be studied in the several stages of its course. An article by Prof. K. HERXHEIMER recently published in Germany makes an important contribution[1] to the knowledge of what is there called Feld-nephritis. It is based on his own observations as well as on those of other German pathologists, and due reference is made to work done in this country. The author finds that when death occurs within eight days of the onset of the disease practically no changes that can be recognised by present methods of fixation and staining are visible in the kidneys. The earliest pathological change is found in the endothelial cells of the glomerular tufts, which swell and show slight fatty degeneration; their lumina become empty of red blood corpuscles and filled with a coagulum. Later there is a proliferation of endothelial cells, infiltration with small cells, and, to a slight extent, proliferation of the epithelial cells that form the visceral layer of Bowman's capsule. It would appear that in its earliest manifestation the lesion is limited to occasional loops of glomeruli; soon the lesion involves the whole or greater part of the tuft and affects the great majority of the glomeruli. Towards the end of the third week the epithelial cells of Bowman's capsule proliferate and the characteristic crescent-shaped masses of cells in the intercapsular space are seen; at the same time adhesion may occur between some part of the visceral and parietal layers of the capsule, and exudation of coagulum and migration of cells into the intercapsular space takes place. In this, the subacute stage, granular, hyaline, and fatty changes are observed in the epithelium of the tubules; the cells swell and desquamate, some of the cells lose their nuclei, and there is an increase in the size of the lumen. In the third, or sub-chronic, stage the fibrous connective tissue of the stroma increases, and fibrosis of individual glomeruli takes place. Prof. HERXHEIMER finds that the primary lesion is limited to the capillary loops of the tufts, and he regards the parenchymatous lesions as secondary to the vascular lesions. Having formed this opinion he looked for evidence of capillary damage outside the tufts, but the presence of minute extravasations of blood from the inter-tubular capillaries and small accumulations of cells in their neighbourhood provided unconvincing evidence of such damage.

The microscopical appearances in the glomeruli in war nephritis were described by SHAW DUNN and McNEE[2] in 1917, and though not worked out in the same detail for the different stages of the disease their work covers the ground traversed by HERXHEIMER; in addition, they made a more careful study of the changes in the body outside the kidney. They demonstrated important microscopical lesions in the bronchioles and infundibula of the lungs, which they compared with the lesions of phosgene poisoning. Their observations are of special interest, because they were able to demonstrate capillary changes in the neighbourhood of the pulmonary lesions, as well as in the brain and spleen. They suggested the possibility of miliary embolism as an explanation of the focal capillary damage observed. These observations were confirmed in their main features by TYTLER and RYLE[3] in 1918; these authors regarded the lesions in the lungs and spleen as the most characteristic lesions of the disease in its acute and early stages. They remark that the tissue changes seen in the glomeruli suggest a local inflammatory process affecting the vascular endothelium, and that while the kidney lesions are constant and characteristic they are not specific. These contributions to the study of the histology of war nephritis are in close agreement in observations of fact, and are authoritative pronouncements on the subject. It is established that war nephritis is a true glomerulo-tubular nephritis. Though none of the authors quoted press the view that acute nephritis is primarily an affection of capillary fields, their work lends some support to this theory. In fact, to quote the paradoxical phrase of Dr. P. AMEUILLE—"Néphrites aigues sans néphrite"—it seems conceivable that "acute nephritis" may occur without "nephritis."

◆

An Apology for Spas.

WE print in another part of this issue a series of articles on continental spas and health resorts, based upon a visit to Savoy and Switzerland by two representative parties of British medical men, the arrangements for the visit having been made by Sir HENRY LUNN with the managers of the resorts and railways concerned. From the glamour of the Alps and the generous hospitality of Swiss and Savoyard it is desirable to disentangle a critical estimate of spas and spa treatment. Although spa treatment is very ancient, most of the baths indeed being already in use in Roman times, the science of balneology is still young, and it has been said with some justice that equipment and technique have advanced far beyond the scientific basis upon which the treatment is based. While this may well be true, the statement would apply equally to modern surgical technique in which the knife, the incision, and the sutures are all marvellously complete and perfect, although the value of the operation may be in dispute. That health resorts heal and baths relieve is quite indubitable, even in the absence of any sufficient scientific explanation, and no one has put this better than a certain Dr. JOSENHAUS in a jeu d'esprit[4] on the discovery of radium in the Wildbad waters, the last stanza of which may be thus rendered roughly in English:—

> At last the learned world has come
> To think the Wildbad cure is real.
> Is this because its waters heal?
> No; they contain some radium.

At some of the spas, at all events, the medical staff is keenly alive to this implication of mere symptomatic treatment. Dr. L. DUVERNAY, of Aix-les-Bains, has recently set out in an able thesis the reasons for thinking that there is a habit of body, aptly expressed by the term arthritism, radically modified by the Aix cure, which therefore does far more than relieve the approached with as much caution as his views on medicine. His thesis that we sleep in order to dream, and his effort to instruct the layman how to analyse his own dreams, must not be regarded as contributions to orthodox psycho-analytical theory or practice.

Repressed Emotions. By ISADOR H. CORIAT, M.D. London: George Allen and Unwin, Ltd. 1921. Pp. 213. 7*s.* 6*d.*

THIS is a popular exposition by the author of "What is Psycho-analysis?" and approximately represents the Freudian view, though the influence of Jung appears occasionally, as shown in Dr. Coriat's attitude regarding the value of the dream. There is some amount of carelessness both in statement and phraseology: that "in the savage there is little or no repression" (p. 79) is opposed to the views of most other workers, and is contradicted by the writer himself on pages 8 and 9. An account of a dream analysis contains the sentence "the analysis released the repressed omnipotence [and] symbolised it like a fairy tale," but even for one familiar with the technical usage of these words it is difficult to guess their meaning. The description (p. 176) of a case of kleptomania reads like an example of simple theft stopped by the old-fashioned method of implanting fear of punishment.

There is plenty of good material in the book, but the exposition of a subject still controversial needs to be handled with more clearness of thought and expression than is shown here.

THE WASSERMANN TEST.

Second edition. By CHARLES F. CRAIG, M.D., M.A., F.A.C.S., Lieut.-Colonel, Medical Corps, United States Army; Director of Laboratories, Army Medical School, Washington. London: Henry Kimpton. 1921. Pp. 278. 25*s.*

THIS volume gives a clear account of the author's method of performing the Wassermann test, incidentally one of the methods authorised for use in the hospitals controlled by the United States Public Health Service. In carrying out the test the hæmolytic power of the complement is standardised as a preliminary. The hæmolytic system consists of human red corpuscles and an anti-human amboceptor prepared from rabbits. In the actual test 2 units of amboceptor and 2 units of complement are used. This necessarily means cutting down the antigen to a relatively small amount, and is contrary to the idea generally favoured in this country, where the most accurate results have been obtained by using a hæmolytic system saturated with amboceptor. This allows of the use of a larger amount of antigen and gives a sharp end-result. The remainder of the volume is mainly concerned with the author's experience of the test and the influence of treatment.

As a monograph on the Wassermann reaction the book is disappointing, and by no means fulfills Colonel Craig's promise to incorporate everything of real value relating to the subject. This is particularly marked as regards British literature; for instance, no mention is made of the important publications of the Medical Research Council on the Reliability of the Wassermann Reaction.

THE SPLEEN AND SOME OF ITS DISEASES.

By Sir BERKELEY MOYNIHAN. Bristol: John Wright and Sons. 1921. Pp. 120. 21*s.*

Sir Berkeley Moynihan has done well to publish in permanent form his *Bradshaw lecture* on the spleen. The lecture at the time of its delivery was recognised as a lucid and learned disquisition on a subject which has given rise to much speculation as well as experimental work. In addition to his skill as an operator Sir Berkeley Moynihan possesses two faculties not always found in general surgeons—a critical faculty which can range over and adjudicate upon a vast amount of material, and an attractive manner of presenting his conclusions. A short chapter on the technique of splenectomy would have been a valuable inclusion; the technique is described in Sir Berkeley Moynihan's book on abdominal operations, but there are several points upon which his views may have changed with increased experience.

The monograph is an admirable summary of modern ideas on a subject of increasing importance, and will find a place on the bookshelf of medical men interested in diseases of the spleen from the medical and pathological as well as the surgical standpoint.

LECTURES ON SURGERY TO NURSES.

By ALAN H. TODD, B.Sc., M.S. Lond., F.R.C.S. Eng., Lecturer and Surgeon to Nursing Staff, Guy's Hospital. London: Edward Arnold. 1920. Pp. 270. 7*s.* 6*d.*

THIS book should be of inestimable value to all nurses anxious for an intelligent understanding of the principles underlying surgical nursing. The author's aim throughout has obviously been to prepare the nurse to become an "intelligent coöperator in everything that is done," realising that much of the surgeon's work can be frustrated in his absence unless those in hourly charge have grasped the fundamental principles of surgery. This is specially true with regard to fractures and dislocations and diseases of the joints and spine, and two excellent chapters on these branches of surgery should do much to increase the interest and understanding of the nurse in her care of these cases. The chief merit of this book lies in the fact that it has been written by a surgeon but from the nursing point of view, and it can be recommended to all nurses in training.

JOURNALS.

IN the *Journal of the Royal Army Medical Corps* for August there is commenced a series of articles on "Malaria in Macedonia," written by the officers of the Malaria Inquiry Laboratory, established at Salonica by the Director of Medical Services, Major-General Sir Maurice Holt. The series opens with a paper on "The Incidence and Ætiology of Malaria in Macedonia," by late Temporary Colonel C. M. Wenyon, who tells us that some 150,000 cases of malaria were reported there in the three years, 1916, 1917, 1918. The epidemic dates from June, 1916, when the force advanced to occupy the low-lying valley of the Struma, to the east of Salonica. All the hill country of Macedonia was malarious, the predominant mosquitoes being, in the low ground *A. maculipennis*, on the high grounds *A. superpictus*. Anti-malarial—i.e., anti-larval—measures could not be taken before the advance which was made into a district swarming with mosquitoes, and in which the malaria-infected inhabitants were nearly all carriers. In 1916 hope was based on quinine prevention, but there were 30,000 cases. The worst cases were sent home, but large numbers of carriers remained in the army. In 1917 much anti-larval work was done; still the unrestricted submarine campaign prevented the removal of the sick, and, partly because of their numerous relapses, 70,000 cases were reported, of which 16,000 in September. In 1918 the year started unfavourably with far more infected and carriers, but the total was 50,000 cases, and numbers decreased after June, because, Colonel Wenyon thinks, 25,000 were sent home through Taranto. This year, too, there was far more individual protection from mosquitoes for the soldier—nets for beds, head nets and gloves, also mosquito-proof wards for the treatment of the infectious sick. Nets must be properly used; Colonel Wenyon saw a patient who had crescents in his blood, and a patch of his bare skin touching his net was simply covered with anopheles. In an extensive, highly malarious area such as this, transiently occupied, protection of the individual men probably does most good. Anti-larval measures cannot go far enough afield to protect against mosquitoes which can travel two miles at is of interest. In the effects of X rays and of radium it is longer still—maybe some weeks.

The committee has established that these powerful searchlights are not less efficient when used with diffusion screens, and it is gratifying to learn that the Association of Kinematograph Manufacturers on its own initiative has given an undertaking to the Minister of Health that its members will not permit the use of open arc lights without filters in their studios. The Committee has accepted this undertaking, but wisely points out that research is needed as to the best type of lamp required.

A CONTROVERSY ON INDUSTRIAL ACCIDENTS.

THE publication in the United States of a *Public Health Bulletin*[1] dealing with the comparison of an eight-hour plant and a ten-hour plant has aroused considerable interest on account of the conclusions drawn from a mass of data carefully collected. Further, the authors have unexpectedly stepped out of their way to attack the conclusions come to in an investigation, made on behalf of the Health of Munition Workers' Committee in this country by Dr. H. M. Vernon,[2] into the causation of industrial accidents. The conclusions arrived at by Dr. Vernon were, briefly, that industrial accidents depend primarily upon industrial risk; in other words, varying speed of production is the factor largely responsible for variations in accident rates. Nevertheless, if the work is so unduly heavy, or so prolonged as to produce over-fatigue, the accident rate rises out of proportion to production, but still the variations in accident rate from hour to hour are in the main governed by variations in output. The American authors considered they had found evidence to justify them in placing greater stress upon the influence of fatigue and less upon risk. Hence the attack. But those who live in glass houses should not throw stones; and immediately the *Bulletin* reached this country, errors were pointed out in these columns vitiating the possibility of relying upon the deductions drawn by these authors, or of accepting the attack on Dr. Vernon as otherwise than unjustified. We pointed out that curves representing the hourly output of all classes of workers were compared with curves representing the hourly occurrence of accidents among the same workers; while data given elsewhere in the *Bulletin* showed that approximately 50 per cent. of the accidents occurred among 34 per cent. of the workers with less than six months' service; "the level of the accident rate varied inversely with the experience of the workers." In other words, output which was mainly contributed to by the 66 per cent. of workers with a service longer than six months—the level of output rate varies directly with the experience of workers—is compared with accidents which are equally contributed to by this 66 per cent. and the 34 per cent. with less than six months' service whose output, being less in absolute amount per man, cannot have materially influenced the general output curve; yet the hourly variations of output among the two groups cannot be expected to have tallied, indeed there is every probability of disagreement.

No attempt to explain this fallacy has been made, and, possibly for this reason, Dr. Vernon has wisely refrained from embarking upon a considered reply. The cudgels have, however, now been taken up in America, and a controversy has appeared in the April number of the *Journal of Industrial Hygiene*[3]; this controversy may have been occupying the full attention of the authors of the *Bulletin*. Here Dr. A. H. Ryan deals at considerable length with the statistical methods employed by the authors. His criticism is keen, but just. He clearly shows that fallacies have crept into the output and accident indices, substantial enough to invalidate the deductions drawn. He holds that "in view of the objections to the output and accident indices, neither can be accepted as valid, either for the plant as a whole, or for a sufficient part of either plant to be truly representative"; and, further, declares the evidence on lost time not to be conclusive, and the comparison between the two plants to be fallacious. Dr. Ryan disclaims being associated with the bulk of the *Bulletin*, and appears to regret that some of his own work, dealing with rhythm in industry, is included in this publication. Mr. P. S. Florence, one of the authors of the *Bulletin*, to whom this stringent criticism was submitted, essays a reply. But it begs the question and is consequently ineffective. He is driven to accept the criticism as well founded, and has to fall back upon being "doubtful whether the refinements which Dr. Ryan suggests would have made any material difference in the conclusions to be drawn." The authors of this *Bulletin*, which has received much notice, would have done well to submit it to much more careful examination before publication. The *Journal of Industrial Hygiene* has done good service in publishing this discussion.

IN DEFENCE OF THE BACILLUS BULGARICUS.

ALTHOUGH Metchnikoff's teaching as to the value of the lactic acid ferment in the large intestine has still many devoted apostles among laymen—especially on the continent—the results obtained and published by medical men who have used preparations of *B. bulgaricus* in their practice have brought little credit on this method of treating intestinal putrefaction. Prof. E. Doumer, of Lille, while he accepted the practical failure of this treatment, was not able to forget that Metchnikoff had to his credit some convincing experiments carried out in vitro. Why, then, did the same experiments inside the human intestine end so differently? His answer,[1] formulated after careful research, is that the bacillus is provided with a nourishing diet in the test tube, while in the intestine he finds himself deprived of all food in the midst of his enemies. Metchnikoff, it seems, had made the mistake of assuming that some starch would survive the action of both ptyalin and diastase, whereas in fact no starch does. Prof. Doumer therefore coats a proportion of starch with paraffin melting at 44°–45° C. Analysis shows that such a mixture provides available starch in the large intestine and the recorded clinical experience tends to indicate that the bacillus is not slow to take advantage of it.

OUTLOOK FOR PHYSICAL RESEARCH.

IMPETUS is being given to physical research in California by an annual grant of £30,000 made by the Institute of Technology for the current expenses of a new laboratory, the equipment of which is being provided by a private donor, at a cost of no less than £60,000. That manufacturers are keenly alive to the benefit accruing to them from physical researches is shown by the participation of the Southern California Edison Company in some of the new activities, for they are bearing the cost of apparatus required for investigations in the transmission of electrical power at high voltages.

Prof. R. A. Millikan has been appointed director of the new institute. A novel feature of the personnel is that Prof. Lorentz of Leiden is to be one of the staff for the winter months, and it is expected that some British experts will be invited to similar temporary appointments. This seems to be an extension of the idea of travelling professorships, and if a galaxy of talent is thus to be made available to the institute far-reaching results may be anticipated. Physical research has an ever-widening range of action and of

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 10, 1921.

The British Association at Edinburgh.

THE British Association met again this week in the city where it had its origin; for the virtual founder of the Association was Sir DAVID BREWSTER (1781–1868), preacher, natural philosopher, and optical discoverer, whose great aim it was to make a permanent organisation with settled establishment, which should not merely come together year by year in a great social reunion, but should give a continuous impulse to every part of the scientific system. The Association met at Edinburgh in 1834 and again in 1850, 1871, and 1892, and Sir EDWARD THORPE in his presidential address on Wednesday evening last indicated some of the aims of his predecessors in the chair and their measure of fulfilment. BREWSTER'S wish to see established in Britain a national institution of resident members devoting themselves wholly to science is still unrealised, although since his time many scientific workers have obtained the place and station in society which he desired for them—respectable and independent—free from the embarrassments of poverty or the temptations of wealth; and the President recalled the claim made for BREWSTER on his death that the improved position of men of science was chiefly due to his exertions and his example. Lord KELVIN, presiding at Edinburgh in 1871, gave expression to the need for experimental research to become an object of national concern, and now in the establishment of the National Physical Laboratory some approach to this ideal may be seen. Industry, too, is beginning to realise that invention depends upon discovery, discovery on research, and research in its turn on training in science, with the result that a Department of Scientific and Industrial Research has come into being, which, while aiding the individual worker, leaves him free to pursue his inquiry as he himself thinks best.

Turning from the general to the special, Sir EDWARD THORPE opened up a question with which all of us are inevitably concerned, whether actively or passively. What is the inner mechanism of the atom? Until this question is answered, much of bio-chemistry must remain on an insecure basis. Although nearly a century since DALTON formulated the atomic theory, it is only within the last few years that our conception of the structure of the atom has become sufficiently precise to be of any service to the chemist. The discovery of the electron, the production of helium in the radio-active disintegration of atoms, the recognition of the existence of isotopes, all these are quite recent discoveries, and with them chemical philosophy has definitely entered on a new phase. One of the most puzzling discrepancies in exact chemistry—namely, the persistently fractional value of the oxygen standard of some atomic weights, while the majority were whole numbers—has recently been cleared up by the ingenuity of Mr. F. W. ASTON, who has shown a number of elements to be in reality mixtures of isotopes. Chlorine has repeatedly given a value of 35·46 and only by an extension of Sir J. J. THOMSON'S method of analysis of positive rays has this gas been compelled to admit that it consists of two isotopes of relative mass 35 and 37. Neon, argon, bromine, boron, silicon are equally complex, while fluorine, iodine, sulphur, phosphorus, and arsenic are apparently simple elements. This discovery has greatly cleared the way to the formulation of an actual physical basis for MENDELÉEFF'S astounding periodic law. Sir EDWARD THORPE made this basis crystal-clear in his address. Electrons appear to be arranged in the atom on the plan that the positive charge is at the centre with the negative electrons around it on the surface of a sphere. Take, he said, the case of the atom of lithium, which is presumed to have one electron in the outer layer. As each element has one more free electron in its atom than its predecessor, glucinum, the element next in succession to lithium will have two electrons in the outer layer of its atom, boron will have three, carbon four, nitrogen five, oxygen six, fluorine seven, and neon eight. As there cannot be more than eight electrons in the outer layer—when more than this the layer of electrons explodes and a new arrangement is formed—the additional electron in the atom of the next element, sodium, cannot find room in the same layer as the other electrons but will go outside, and thus the atom of sodium, like that of lithium, will have one electron in its outer layer. On this disposition depends the atomic number and the valency. Happy are the students to whom the facts of physico-chemistry can now be presented in such reasonable and attractive guise.

To the Section of Physiology Sir WALTER FLETCHER, secretary of the Medical Research Council, gave a short presidential address which those interested in the next stage of medical education will find suggestive (see p. 541). For the story of the rise of physiology, of its early connexions with anatomy, its subordination to specialism, and its later developments into a broad and general science, is a great example of the way in which the work of separate schools and separate individuals can, under an organised university system, become a homogeneous and forceful whole. And in this development and consolidation of the very foundations of modern medicine, the science of our own country has played a leading part, as could be insisted upon appositely in an address to the British Association. Sir WALTER FLETCHER referred to the synthetic tendency of modern physiology because of its practical bearing upon the present development of the subject in the universities and medical schools. There is no doubt that the whole conception of physiology to-day by teachers and by taught is larger and fuller. We all see that a knowledge of the general processes of life and of their interplay is necessary for the comprehension of the pathological problems, large or small, which present themselves, as serious or rare events in hospital wards and casualty rooms, and on everyday occurrences in routine practice. Through physiology and through physiology alone can be learned the guiding principles of treatment, while it is also to physiology that we now look for assistance in the development of preventive medicine made possible by early diagnosis.

POTT'S DISEASE IN ADULTS.

THE recent tragic death of Mr. H. G. Hawker in an aeroplane crash was a reminder that tuberculous disease of the spine is not a very rare condition in the fighting forces. In the *Archives de Médecine Militaires* for May Lieut.-Colonel Courboulès reported from a hospital at Metz 140 cases of Pott's disease under treatment among soldiers and ex-soldiers aged between 20 and 50, during the period from March 1919 to June 1920. He makes a convenient summary of the salient features of the disease. In soldiers it only rarely develops acutely; one man did over two years' service in the artillery without a day's illness, complained of a swelling in the abdomen which, opened 10 days later, was found to be associated with disease of the dorsal vertebræ. Eighteen were correctly diagnosed at once. Many had suffered from lumbago, rheumatism, or sciatica, with no pathognomonic localising symptoms even for as long as 15 months. Rarely they are ascribed to accidental injury. Hernia, chronic appendicitis, ischio-rectal abscess, even gastric ulcer were accused as causes of the condition. The signs are curvature, paraplegia, abscess; pain is rarer than in children, and loss of function comes on more gradually in the adult, whose disease begins most frequently in the lumbar region, which was concerned in over 100 of this series. One case sent in had really a lipoma over the dorsal region and a malignant tumour of pancreas and liver. Cold abscesses (abcès pottiques) existed in 109 cases, mostly lumbar, iliac, or femoral, but two were perineal and two were retro-pharyngeal. Their course was incalculable; one with a femoral fistula also opened into the bronchi, but that was in a child. The characteristic constrained attitude with stiffness of the back, obvious when a patient tries to pick up an object off the floor, helps in diagnosis, which X ray examination facilitates materially. The treatment is rest in bed, extension, and Sayre's plaster jacket. The abscess must be opened by puncture under stringent aseptic precautions. Cure may follow Carrel-Dakin treatment; 12 cases of such recovery are mentioned, but even that may fail. Some recover unexpectedly, the general condition having improved. A cure cannot be ensured under two or three years of immobilisation. There is hope in bone grafting along the sides of the vertebral processes, fusion of which is the natural cure. Mr. Tuffier has even planted a graft from the occipital bone along the cervical spines, but Colonel Courboulès commits himself to no opinion whether surgical treatment brings cure more quickly and more certainly than does immobilisation.

THE CHOICE OF DENTAL ANÆSTHETICS.

THE latest issue[1] of the National Anesthesia Research Society's bulletin, a periodical which bears constant testimony to the enthusiastic pursuit in America and Canada of improvements in anæsthesia, is largely occupied by a paper on dental anæsthetics. The author contrasts the advantages and disadvantages of nitrous oxide and oxygen with analgesia by local injection. He believes that the former is "undoubtedly the superior method in the vast majority of cases." He is, however, at pains to point out that more skill is required of the operator during the anæsthesia of nitrous oxide and oxygen than during the leisurely operating possible with an effective analgesia. We gather that dentists in America concern themselves with the administration of anæsthetics to a greater extent than is usual, at any rate in big towns, in this country. For the writer remarks that it behoves all dentists to "acquaint themselves with the correct methods of administering nitrous-oxide-oxygen." That the present practice is not altogether satisfactory, however, we deduce from the observations of the chairman of the National Dentist Association meeting. He observed that the regrettable accidents of the past were all due to anæsthesia, and that the "surgeon should insist that the anæsthetic be given by a professional anæsthetist and not by an interne or by someone who gives anæsthetics as a side line. We should only trust our anæsthetics to professional anæsthetists for the reason that they are not interested in surgical technique and therefore are not likely to neglect their patients." There are, of course, innumerable occasions when such an ideal arrangement cannot be carried out, and in this country many dental anæsthetics are given by practitioners without special experience. There is a growing tendency to recognise the fact that even these comparatively minor operations involve the patient, as far as the anæsthetic is concerned, in a certain amount of risk. The patient, however, naturally weighs risk against discomfort, and it is probably true that a number of people would greatly prefer to take a minute risk from gas rather than undergo the discomfort of local anæsthesia. The prodigious crunching noise, the anxiety engendered by previous experience or by the recitals of other sufferers, the prospect of swollen gums, these minor but still appreciable ills make "freezing"—as it still appears to be called—unpopular among those who take nitrous oxide well. Doubtless the more complete the anæsthesia, the more satisfactory and painless will be the operator's endeavours. But the last word has not yet been said on a choice in which the public is very keenly interested.

THE REGULATION OF THE REACTION OF THE BLOOD.

AN elaborate communication by Dr. C. Lovatt Evans to the current number of the *Journal of Physiology* describes experiments dealing with the relative parts played by various modes of buffering in the blood in regulating its hydrogen-ion concentration, this concentration being determined by the indicator method described by the author and Dr. H. H. Dale. The term "reaction of the blood" is understood to mean the reaction of the plasma (or serum), as it has been shown that there is no difference between the reaction of blood and that of its plasma under identical conditions. The methods used for the blood of man, goat, and horse are fully described. The view that the reaction of plasma, like that of a bicarbonate solution, is dependent on the ratio $NaHCO_3/CO_2$ is confirmed; it is shown that the actual reactions of the plasma and of a bicarbonate solution of identical bicarbonate content are not identical; the plasma is more acid than the bicarbonate solution at the same CO_2 pressure, the difference being due principally to the sodium chloride present in the plasma. The influence of the proteins of the plasma is very small, and there is no evidence of any buffering action by the proteins. Plasmas from different bloods and of different alkali reserves have CO_2 reaction curves parallel to one another. The carbon dioxide reaction curves for different bloods are not usually parallel with one another; the discrepancies are due to differences in the hæmoglobin content, and in the extent and range of the ionic interchange between corpuscles and plasma (secondary buffering), and to somewhat capricious chemical alterations in the corpuscles on standing, whereby the secondary buffering is liable to modification. The greater the hæmoglobin content (and the lower the alkali reserve of the whole blood) the flatter the reaction curve of the blood tends to become. Although the CO_2-fixing capacity of blood falls off on standing, it is the corpuscles which, at a given pressure of CO_2, are most affected. The reaction of a blood is that of its "true plasma." Owing to the secondary buffering, the reaction of the "true plasma" alters less rapidly than that of separated plasma when the CO_2 pressure is altered. Plasma and blood, like bicarbonate solutions, are at the same CO_2 pressure more alkaline at higher temperatures, owing to the reduced solupainful manifestations of rheumatoid disease A course of spa treatment may modify the terrain to such an extent that the body recovers its equilibrium And to the patient this equilibrium is the essence of health It has been contended again with some show of justice that the unsuccessful results of spa treatment are not reported In a country village the doctor s failures go about the only street on crutches, the failures of spa treatment, like those of fashionable quacks, are scattered far and wide and have no means of speaking with a common voice Still in the long run it must be on actual concrete results that success depends, as may be seen from the fact that within the larger resorts there are always smaller units which enjoy continuous patronage while success waxes or wanes around them, and this success must depend on a good report handed on from patient to patient by word of mouth A frescoed notice in an Upper Engadine bath runs

---

[1] Current Research in Anesthesia and Analgesia, 1921, Bulletin No. 13.

The scientific individual adaptation of the prescription increases the efficiency of the cure uncommonly and several Engadine resorts have scientific workers of university standard among the practising doctors At St Moritz Bad Dr S HEDIGER is working out the effect of baths upon the volume of the pulse, using the sphygmovolumeter designed under Prof O VERAGUTH at the Zurich Institute for Physical Therapy At Tarasp Dr E LENZ who lectures on pharmacology at Berne has shown by exact observation that a week in a subalpine climate may act precisely like a digitalis cure

Health resorts have been known to cry up their own wares and decry those of others but there need we think, be no jealousy as between spa and spa There is a mass of relievable chronic ill health which does not necessarily show on any monthly mortality return, and which yet reduces in large measure the efficiency and happiness of the community Much of this can be mitigated or relieved by spa treatment, and there must be resorts for many different tastes Some undoubtedly possess such wealth of natural advantage that it is hardly human to expect an equally high standard of art others less favoured by Nature have built up a substantial and sufficient reputation by performing well all the adjuvants of treatment It may be recalled that the mere climate of the Black Forest in which the late OTTO WALTHER made the name of Nordrach world famous has little enough to recommend it As between home and abroad a little competition is good for both spa and patient, and it is open to our own resorts to cater for the outlander just as they do for us The captain of the Syrian host in lauding the virtues of his own home waters over the Jordan apparently was not speaking from actual personal experience of them We can hardly bring to the Welsh or Yorkshire uplands the blue sky and pellucid air of the south, yet the Aix massage, the Plombières douche, or the Nauheim bubbly bath may be equally effective wherever they are individually and skilfully applied

LIGHTING IN KINEMA STUDIOS

THE effect of ultra violet radiation on the eyes has interested ophthalmologists for many years, it was discussed at the International Congress of Medicine in 1913 and papers on the subject have appeared at intervals since Now the matter has again come into prominence owing to the results of the use of powerful arc lamps of American make in British kinematograph studios during last year Some of the actors and actresses developed a form of conjunctivitis after working in this intense light, and the matter was referred by the Minister of Health to the Committee on the Causes and Prevention of Blindness This committee has now issued an interim report

Each division of the spectrum is associated with certain characteristic effects—radiant heat with the infra red, light with the visible part and chemical effects with the ultra violet—but the visible part has thermal and chemical properties too as well as that of light Radiant heat induces erythema of the skin, which reacts and thereby protects itself by sweating The moist eyeball is similarly protected and the fluid media of the eye act as an absorbent screen Heat rays seldom reach the retina although they are refracted in the eye exactly as are light rays They do reach the lens when the eye is subjected to prolonged exposure, cataract in glass blowers is sufficient confirmation of this Visible rays in excess induce another protective measure—blepharospasm which is a characteristic feature of the typical albinotic facies The kinema actress however must usually voluntarily dispense with this protection, so many emotions are associated with sympathetic nerve stimulation and induce a wide palpebral aperture The most familiar protective result is a contracted pupil and the ocular pain complained of probably results from stimulation of sensory nerve endings in the iris

Dazzling is an interesting if distressing phenomenon Its usual cause is a corneal or lenticular opacity which scatters instead of refracting the rays of light But the normal cornea is not quite transparent and some diffusion occurs in the eye with ordinary illumination Under conditions of excessive illumination this increased diffusion will cause dazzling Excessive light also may enter the eye through less transparent structures such as the iris Indeed the position of the normal man in relation to intense light is that of the albino in relation to ordinary light Erythropsia is associated with a large pupil and with aphakia It is due to the visible rays, but the ultra violet rays if not essential to its production materially assist It is a common accompaniment of snow dazzling, and light reflected from snow is rich in ultra violet rays The lens absorbs ultra violet rays and it also converts them into waves of greater wave length, producing the phenomenon of fluorescence of the lens A large pupil is a sign of sympathetic stimulation and in the business of acting must be an almost habitual occurrence Erythropsia should be a familiar after effect of kinema acting in intense light, it might almost be taken as an index of the emotionalism of individual actors and actresses

The symptoms attributed to the intense lights used for the production of films are exactly those of snow blindness and electric ophthalmia and like erythema of the skin after exposure to unusual amounts of sunlight are due to the actinic or ultra violet rays After a latent period of half or one day follow redness of the lids injection and chemosis of the conjunctiva, photophobia, and pain Erosions of the cornea have been described after exposure to light from the arc used in electric welding and stress is usually laid on contraction of the pupils This is not due however, to the stimulus of light, for congestion miosis is common in all corneal and conjunctival inflammations The symptoms pass off in a few days The latent period animals. The chief medical officers, Dr. Marshall and Dr. S. Vassallo, will have the assistance of two junior colleagues, two veterinary surgeons, and a secretary, and the object of the mission is to carry out treatment of infected cases by the serum method, with such experimental variations in technique and general principles as may suggest themselves, and to make general observations on the pathology of the condition, with a view to prevention and immunisation in man and animals. As the expedition is to be organised on such a broad basis, we would suggest that attention be also paid to the action of trypanocidal drugs, such as the organic compounds of antimony, and to the remarkable new compound known as Bayer 205. Mayer and Zeiss[2] have shown that in experimental animals this drug has a direct action upon the trypanosome, whether given subcutaneously, intravenously, or into the stomach. They have also shown that the drug is comparatively non-toxic, and that it exerts a prophylactic as well as a curative action, though in vitro it exhibits no marked predilection for the trypanosome. It is claimed that this drug far excels all known trypanosome remedies, for it confers a protection against fresh infection which lasts for months. We understand that these somewhat astounding results are now being confirmed in this country, and that the minimal lethal dose is perhaps more than one hundred times greater than the therapeutic dose. It may be that upon these lines ultimate success will be attained, and it is perhaps in this direction that the new sleeping sickness commission will ultimately move. A concerted investigation will certainly stimulate fresh interest in this terrible scourge of Africa, and we wish the proposed expedition every success in its labours.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

The following appointments have been made:—Surg. Comdr. J. S. Austin to the *Caroline*. Surg. Lieut. W. J. McB. Allan to the *Dolphin*.

Surg. Lieut. A. C. Anderson to be Surg. Lieut.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Maj.-Gen. J. B. Wilson retires on ret. pay.

Maj. W. Byam retires, receiving a gratuity.

Capt. J. E. Brooks is secd. for service under the Colonial Office.

Capt. A. R. F. Clarke is secd. for service with the Egyptian Army.

TERRITORIAL FORCE.

Capt. W. Barclay to be local Maj. whilst specially empld.

Capt. H. F. Humphreys to be Maj.

Lieut.-Col. J. McKie resigns his commn., and retains the rank of Lieut.-Col., with permission to wear the prescribed uniform.

Maj. R. B. Carslaw resigns his commn., and retains the rank of Maj.

Capt. J. W. Anderson resigns his commn., and retains the rank of Capt.

Capt. C. H. A. Alderton (late R.A.M.C.) to be Lieut.. and relinquishes the rank of Capt.

Capt. J. B. Bate and Capt. J. A. Cooke, having attained the age limit, are retired, and are granted the rank of Maj.

Capt. J. K. Lund to be Maj.

Capts. A. D. Low (late R.A.M.C.) and D. O. Macdonald (late R.A.M.C., Spec. Res.) to be Capts.

J. S. Pegum (late Unattached List, T.F., O.T.C.) to be Lieut.

Capt. R. A. Quinn (late R.A.M.C.) to be Lieut., and relinquishes the rank of Capt.

2nd N. Gen. Hosp.—Capt. A. L. Whitehead, having attained the age limit, is retired, and is granted the rank of Maj., with permission to wear the prescribed uniform.

1st W. Gen. Hosp.—Capt. H. Armstrong, having attained the age limit, is retired, and retains the rank of Capt.

ROYAL AIR FORCE.

Flight Lieut. H. J. Swan relinquishes his temporary commission on ceasing to be employed, and is permitted to retain the rank of Capt.

ALPINE AND SUBALPINE CLIMATIC TREATMENT.

I.—THE PLACE OF ALPINE SPAS IN MEDICINE.

By E. Bosdin Leech, M.D. Camb., F.R.C.P. Lond.,

HONORARY PHYSICIAN, MANCHESTER ROYAL INFIRMARY.

Switzerland abounds in spas; there are said to be 108 health resorts in this small country. When considering that small section of these which is visited by British patients, it is fair to remember the existence of the others. The Swiss spas correspond, so far as their waters are concerned, to those of the surrounding countries, and the medical officers of the spas of Switzerland only follow the suit of their colleagues in other countries when they recommend their own spas for nearly every type of illness. It is therefore essential in choosing a spa to sift the special from the general and to recognise that a place is not made by the exact amount of salt in its waters.

Two Great Assets of the Alps.

The Swiss spas possess, in varying degrees, two great characteristics, and it may be said safely two great assets, which stamp them and which cannot be neglected in estimating their value; whatever advantages accrue from the constituents of the waters, these are present in addition. One of these is altitude. Switzerland begins where other countries leave off. Baden-les-Bains (to be distinguished from Baden-Baden in Germany and Baden in Austria) lies at 1250 feet; St. Moritz, the highest, at nearly 6000 feet. We may choose a spa for its waters or its establishments, but a stay has only to be made at Tarasp, St. Moritz, or Montana, to realise what an asset is the freshness and sunshine of the mountain air. The advantage of high altitudes for tuberculous cases is proved by the records of Montana, Leysin, Arosa, and Davos; the advantage of high altitudes for other diseases is not so well recognised, but is present nevertheless for many of these. The other great claim of Swiss spas on the attention of the world is the beauty of the surroundings; the special beauty of what may be called the Swiss mountain type cannot fail to react favourably whether like hospitable Lucerne on the tourist or restful Pontresina on the invalid. This asset of scenery cannot be left out of count.

Any plan adopted would fail to place even the important resorts into exact groups, but the following rather rough classification will be helpful. The spas may be divided into: 1. Those which depend largely on their waters. 2. Climatic resorts (*a*) for tuberculous cases, (*b*) summer resorts, (*c*) winter resorts. The first class is mainly considered here, but a few points may be mentioned with regard to the others. Tuberculous patients should be sent only to those centres where the treatment of tubercle is paramount, and non-tuberculous patients should avoid places where tubercle is admitted, especially those places which, professedly simple health resorts, admit convalescent or "healed" tuberculous cases. On the one hand, phthisical patients are liable to relax the necessary discipline when they are in sports or tourist centres, and on the other hand compulsory disinfection of rooms is only carried out where the presence of tubercle is officially recognised.

General Character of the Spas.

Sanatoriums in the tuberculosis centres are thick on the ground and usually are well furnished and well managed. There are some institutions in non-tuberculosis centres for the exact diagnosis and treatment of digestive and metabolic diseases; the Chantarella at St. Moritz is an excellent example of these. Practically all the spas have a summer season only, early June to late September; only some of the upland places as Pontresina and St. Moritz have both summer and winter seasons, the former contemporaneous with the tourist season, the latter with that of winter sports. The sanatoriums cater for patients the application The whole problem of available power for the service of man is a question of the possible mode of transformation of the various forms of energy Physical research has shown the laws which govern these transformations but the new knowledge arising out of radio active and associated problems has pointed to the indisputable fact that within the atoms a vast source of energy exists The question that confronts the physicist to day is whether this source of energy may be made available Only a comparatively minute fraction of the atoms liberate any of their energy spontaneously, these being the radio active ones The probability of releasing energy on a large scale from the atoms which are the bricks of the structure we call the world, is difficult to estimate, but atomic studies are a necessary precursor to it Medical interest in physical research has received a great stimulus as electricity and the many forms of radiation become more and more wielded in its service

[2] Arch. f. Schiffs u. Trop. Hyg., 1920, xxiv., No. 9, 257–294.

It is impossible to read of the many benefactions to research in all its forms in America without some regrets that these are such seldom events in this country Here the academic world is not at the present time getting the number of men it should to devote themselves to pure research Should this state of affairs continue it will be a bad day for physical research, and the British school of physicists will hardly maintain its proud record The need is not so much for institutes since excellent laboratories exist throughout the country, what is wanted is facilities whereby men can carry out researches after qualification and before taking up senior appointments which carry a livelihood with them.

OCULAR REACTIONS IN ANAPHYLAXIS

RECENT experiments have shown to what an extraordinary extent the excitability of the smooth muscle of the uterus intestine, blood vessels, and lungs can be increased in guinea pigs sensitised by anaphylaxis R Kodama[1] investigated the smooth muscle of the eyeball and its surroundings in guinea pigs sensitised by the injection of 0 01 c cm and in other experiments by injecting 2 5 c cm of horse serum under the skin The anaphylactic sensibility was after a few weeks produced by dropping the same serum into the conjunctiva, or by intra orbital, intravenous, or subcutaneous injection control experiments being made on non sensitised guinea pigs The palpebral fissure and pupil were accurately measured In both normal and sensitised animals the application of horse serum to the conjunctiva caused at once a dilatation of the palpebral fissure and pupil followed by narrowing of both In sensitised animals the reaction was both quicker and more marked The primary dilatation was due to the stimulation of the smooth elevator fibres of the eyelids and the dilator of the iris The secondary narrowing of the palpebral fissure and iris is due to two factors—decrease of the tonus of the tarsal muscle and dilator iridis and contraction of the sphincter iridis and congestion of blood The primary stimulation of the smooth muscle of the eyelids and dilator iridis requires only a very small dose of the anaphylactic poison, whilst the sphincter pupillæ is acted on later and is brought into action with more difficulty These reactions of the smooth muscles of the guinea pig seem to show that the terminations of the sympathetic nerve as well as those of the oculo motorius are affected by the anaphylactic state Injection of horse serum into the orbital cavity, as well as intravenous injection both in normal and sensitised animals caused increased secretion of the lacrymal and Harderian glands as well as vaso motor disturbances and sometimes hæmorrhage from the epibulbar and retinal vessels In anaphylactic death there was a sudden contraction of the pupil All the reactions occurred equally whether normal horse serum was used or serum that had been heated for some time at 56° C

THE INFLUENCE OF ARSENICAL PREPARATIONS ON CUTANEOUS TESTS

ARSENIC has a selective action upon the skin in a number of ways not yet clearly understood Dr Albert Strickler[1] professor of dermatology and syphilology at the Temple University Philadelphia has carried out a series of investigations to determine the influence of various arsenical preparations on the luetin Pirquet and anaphylactic food tests The influence of a repetition of the luetin test was first examined without any arsenical preparation being used Two Wassermann tests were made on each patient both of which had to be negative before the cases were regarded as eligible In the repetition of the luetin test positive reactions were obtained in three out of 14 cases Dr Strickler suggests that the positive reaction was due to sensitisation of the skin produced by the first inoculation of dead spirochætes The influence of intravenous injection of arsphenamin on the luetin test was then examined in 17 patients suffering from various skin affections two negative Wassermann tests as in the first series having first been obtained The patients were given from two to five injections of 0 4 g before the luetin test was repeated in each case Nine of the patients gave a positive luetin test on repetition and eight responded negatively Intravenous injection of cacodylate of soda acted in the same manner as arsphenamin only more feebly A study of the influence of the intravenous injection of arsphenamin on the Pirquet test showed that arsphenamin acted on the tuberculin test in the same way as it had acted on the luetin test as in three out of ten cases a previously negative Pirquet test became positive On the other hand, the anaphylactic food test made by either the endermic or scratch method did not seem to be influenced by the intravenous administration of either arsphenamin or cacodylate

SILVER SALVARSAN

Dr H E Michelson and Dr David M Siperstein[2] of the University of Minnesota discuss the therapeutic value of silver salvarsan or silver arsphenamin as it is known in America The drug was suggested by Ehrlich shortly before his death and first used clinically by Kolle in March 1918 since when it has enjoyed a considerable vogue in Germany, but does not appear to have been used to any extent in this country or in the United States From a study of the literature and their personal experience of a limited number of cases the writers conclude that silver salvarsan is an efficient spirochæticide which has a pronounced effect upon the visible lesions of syphilis A distinct advantage is the absence of the characteristic and often nauseating garlic like odour noticed by the patient when receiving other forms of salvarsan intravenously The effect of silver salvarsan on the Wassermann reaction is variable As a rule, however in recent syphilis a positive reaction becomes negative after the first course of from six to ten injections of silver salvarsan Authorities differ considerably as to the optimum dosage An initial dose of from 0 05 to 0 1 g for a person of average weight is best with a routine dose of from 0 2 to 0 25 g The following technique is recommended by the writers Dissolve the necessary dose in 10 c cm of sterile distilled water draw into a 20 c cm Luer syringe, puncture the vein aspirate about 10 c cm of blood and re inject the entire solution slowly The interval between the injections should vary from four to seven days and the number of doses in a series varies considerably There is apparently no reaction peculiar to silver salvarsan which has not been noticed with any of the other salvarsan preparation No authentic case of argyria has been reported Immediate reactions are about the same as with the other forms of salvarsan, but it is too early to speak with certainty of remote dangers

[1] Archives of Dermatology and Syphilology Aug [illegible] 1921

[2] Ibid

September, but the hotels in St. Moritz Dorf are open the whole year.

Pontresina, 5000 feet, not far from St. Moritz, is a health resort of the first order which owes its pre-eminence to the pure invigorating air and beautiful surroundings. It possesses no special waters, but is an ideal place in summer for convalescence or for an after-cure. The opportunities for winter sport are good and in this season it is likely to be frequented much by English visitors. Consumptives are not catered for.

Montana, about 4800 feet, lying above Sierre in the Rhone valley, on the open hillside and with a magnificent view, is becoming more and more a centre for tuberculosis. The proportion of English patients, who centre round the Palace Hotel, is a big one. Opportunity for the milder exercises, suitable for consumptives, is provided without the temptations of a recognised sports centre.

Arosa, 6000 feet, situated in a basin in the mountains of the Grisons canton, and thus effectively protected from winds, is a leading resort for tuberculosis. Sports, as at Montana, are within limits which are not likely to lead patients away to harm. The treatment of tubercle is taken wholeheartedly and the medical fittings of many of the sanatoriums are very good.

Davos, 5200 feet, in the Grisons, in a broad, smiling valley, is the oldest of tuberculosis centres. It possesses a great number of sanatoriums. One may mention the magnificent and well-managed sanatorium, the Schatzalp, and its kindly director, Dr. E. Neumann, and one may mention, too, with sadness the fine Queen Alexandra Sanatorium for persons of small means, restricted to English-speaking nationalities. Everything there is ready for further use, but it has been closed since the early part of the war and cannot be reopened for want of funds. Both these institutions lie well above the town. Davos is a centre for winter sports; there is a fairly large English population here.

Aix-les-Bains, Haute-Savoie, France.—This town possesses hot sulphur springs (113° F.). The baths are numerous and well-fitted. The renowned Aix douche involves simultaneous douching and massage and does not fail to quicken the circulation in the affected part. The surrounding country is beautiful with its mountains and lakes, and is historically interesting. The hotels are good; the casino and theatre help to make Aix, as is well recognised, one of the most typical and successful of continental spas.

II.—SWITZERLAND AND "NERVES."

BY S. A. KINNIER WILSON, M.D. EDIN., F.R.C.P.,

JUNIOR NEUROLOGIST, KING'S COLLEGE HOSPITAL.

PHYSICIANS, according to *Mr. Punch*, are divisible into two classes only—those who "run" their patients, and those whose patients "run" them. We all have encountered the type of patient, not exactly a rara avis, who meets every suggestion for treatment with a qualifying "but," and dominates her entourage, physician included, from her bed. Endowed with une faiblesse herculéenne she exhausts and annoys everyone except herself. In the bad old days before the Entente, an Englishman was once defined as "un monsieur qui gêne les autres chez lui, mais qui ne se gêne pas chez les autres," and, mutatis mutandis, the same is largely true of this type of patient in relation to his or her medical attendant. A positive nuisance such people may become, and that they should sometimes be cordially if secretly consigned to another place of residence need not occasion surprise. In contrast stands out the patient of the clinging type, who depends for sustenance on the mental and physical vitality of others, and who, parasite-like, digests what someone else eats. Both types are in reality "running" their doctor, and sometimes not much less than a mental earthquake is required to get them to see themselves as others see them. But the physician, properly so called, manages his patients as well as treats them: his savoir faire enables him to praise or blame, caution or encourage, accept or reject, not indiscriminately but with knowledge. We should cut a sorry figure were we to rack our brains for a convenient sedative or tonic for the love-sick maiden and fail to see the little god laughing at our discomfiture as he sits at the foot of the bed, or exhibit our favourite hypnotic for the city man's insomnia without taking the trouble to learn that he has a "deal" on, which may make or mar him for years.

SUBALPINE CLIMATIC STATION.

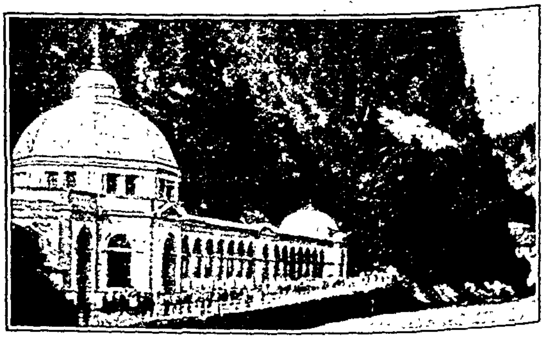
TYPICAL BATHS.



The pump-room and riverside promenade at Tarasp Vulpera in the Lower Engadine.

bility of carbon dioxide. In the same number of the *Journal* Dr. J. S. Haldane records attempts to produce an acidosis in man and to study the corresponding symptoms. He found that ingestion of ammonium chloride in man causes marked and prolonged acidosis. The symptoms include fall in the alveolar CO_2 and in the blood's CO_2 capacity, and increased excretion of acid, ammonia, and phosphates. This is probably due to the conversion of part of the ammonia into urea, thus freeing the acid which has been combined with it. The depression of alveolar CO_2 below a certain value is roughly proportional to the rate of excretion of acid plus ammonia. The ratio of acid to ammonia in the urine depends on the amount of phosphates available for excretion. This amount falls during acidosis.

THE REFRACTORY IRIS.

THE Vienna School of Ophthalmology recently celebrated the seventieth birthday of Prof. Ernst Fuchs in a special number of the medical journal.[1] Among the numerous articles on ophthalmic subjects is one purporting to answer a question which must often have puzzled those who do refraction work. Why is it that the action of homatropine as a mydriatic, though entirely satisfactory in the great majority of cases, is in a few uncertain? The answer suggested is that in the eyes of certain people the anterior surface of the iris is more or less devoid of the crypts that are normally present, that in these cases the surface is comparatively smooth, and further, that these exceptional irides are exclusively found in brown eyes. This formation of the iris, though it cannot prevent the absorption of atropine, may partially or in exceptional cases completely prevent the absorption of homatropine. Dr. G. Guist, the writer of the article, found that in 24 out of 9500 patients homatropine completely failed to paralyse the pupil, whereas atropine succeeded. Whether or not the reason suggested by him is the true one should be easily ascertainable if the attention of a sufficient number of workers at refraction is directed to the subject. Paralysis of the pupil of course is not the same thing as paralysis of the accommodation, but the two conditions are intimately connected. If the explanation offered is correct, stubbornness to homatropine should be far commoner among negroes than among white people, and, so far as is known, this appears to be the case. In confirmation of his theory the author cites three cases of heterochromia in which the blue iris was easily paralysed by homatropine, whereas the brown one remained resistant, or nearly so, to the drug.

KERATOMALACIA IN RATS.

EVERY physician knows the importance of an appropriate and adequate diet in certain diseases of the eyes and eyelids, and the study of deficiency diseases in recent times has shown an intimate connexion between a lack or want of vitamin A in the food and the occurrence of certain nutritive disorders of the eyeball. Observations in this connexion have been made by Knapp, Falta and Noeggerath, and T. B. Osborne and L. B. Mendel. The last-named workers have extended their observations,[2] and find in their feeding experiments on young rats that these changes in the eyeball—keratomalacia, xerophthalmia—occur *only* in the absence of vitamin A in the diet. Among 1000 rats, those fed on a diet free from vitamin A showed these pathological eye phenomena, whilst of other rats fed so as to be but poorly nourished, on food containing vitamin A, not a single animal showed keratomalacia. That this condition is not the consequence of simple malnutrition is further shown by the fact that the eye symptoms usually begin before there is a decrease in body weight. In 61 cases, 33 animals showed the phenomenon before there was any loss of body weight, 15 before the loss of body weight reached 10–20 g., and 13 before the body weight loss reached 20–30 g. A daily addition of 0·1 g. of butter fat or vegetable oil (extract of plants, grass, alfalfa, spinach), caused the diseased state of the eye to disappear in two weeks, and a local improvement of the condition in cases where death could not be prevented. Isabel M. Wason has determined the pathological histology and bacteriological condition of some of these cases of keratomalacia. In all there was hyalinisation or necrosis of the outer layers of the corneal epithelium, œdema and infiltration of the epithelium and stroma, and proliferation of the blood-vessels and fibroblasts. In advanced cases the anterior chamber and occasionally the posterior chamber of the eye were involved. Staphylococci, streptococci and pneumococci, and pseudo-diphtheritic bacilli, or "diphtheroids," were found in the conjunctiva. But, so far, there is no explanation as to how the absence of vitamin A in the diet brings about such localised and specific changes in the superficial structures of the eyeball.

THE TREATMENT OF SLEEPING SICKNESS.

THE serum treatment of trypanosomiasis is based upon similar work in syphilis of the central nervous system. Although this line of treatment was received with considerable enthusiasm some six or seven years ago, it is now generally admitted that salvarsanised serum exerts little or no action upon syphilitic lesions of this specialised tissue. The intrathecal injection of salvarsanised serum in trypanosomiasis was originally proposed by Andrew Balfour in 1913, and was tried by R. A. L. Van Someren in Uganda on a small scale with inconclusive results. To the *Deutsche med. Woch.* (1914, xl., p. 203) Reichenow contributed an account of inconclusive results in a considerable number of cases treated by this method in the German Cameroons; from private sources we learn that this form of treatment has also been given a trial on the Congo. Dr. C. H. Marshall has published some remarkable results; 52 natives and one European under his care were apparently cured of their infection by the intrathecal injection of varying quantities—from 1 to 10 c.cm.—of their own salvarsanised serum. These results were summarised in a paper read before the Royal Society of Tropical Medicine and Hygiene on May 20th, 1921, when an interesting discussion followed his paper. The advocates of this method of treatment are convinced that the presence of trypanosomes in the cerebro-spinal fluid is the main factor in the production of the sleeping sickness state, and that by the introduction of the salvarsanised serum into the spinal canal the parasites can be destroyed. They do not claim that salvarsan or its derivatives exercise any special trypanolytic action, but that such action is possessed by the serum abstracted from the patient's blood three hours after an injection of 0·6 g. of neokharsivan.

The assumption that trypanosomes are invariably present at some time or other in the cerebrospinal fluid is by no means generally accepted; their appearance in this situation may be entirely fortuitous. Stevenson has demonstrated to the Royal Society of Tropical Medicine and Hygiene these bodies lying outside the blood-vessels, in sections of the cerebral cortex and other organs of experimental animals. Very recently Clapier[1] has found them in large numbers in hydrocele fluid (in this instance it was not claimed that *Trypanosoma gambiense* was the cause of the condition, as these bodies may possibly invade and multiply in any collection of serous fluid). The arguments in favour of a serum treatment of trypanosomiasis have been ably put forward by Prof. J. W. H. Eyre and Dr. Marshall, and it is now proposed to apply this method on a much extended scale. The Colonial Office has approved of the proposals made by a recently formed body—The Tropical Disease Prevention Association—to send a special mission, at an outlay of £50,000, to investigate the serum treatment of trypanosomiasis in man and

Rest and Change.

Of course, when we have the wit to see that our inventiveness in therapy is beginning to run dry we can always counsel a rest and a change, and if we can do this with the air of the pundit the suggestion may be hailed with acclamation. But let us beware of facility herein. It scarcely serves to recommend a long sea voyage for our neurasthenic patient, only to be told that he has followed the sea for years, or to enjoin the depths of the country to another in whose hair hayseed can almost be seen. Rest is indeed change of occupation; otherwise how can we explain the rejuvenating effect on the "t.b.m."[1] of the Ziegfeld Follies at midnight, on a roof garden in New York? Some folk like crowds and are refreshed thereby, witness the popularity of visits to the metropolis by those who live in the country and need a holiday. Seaside people go inland, while town-dwellers rush to the sea. Each one, in short, wishes a specific antidote for his particular variety of out-of-sorts-ness, and the finding of this antidote is for the physician in many instances. Marion Crawford has said somewhere that for the sensualist there is Aix in Savoy and for the sybarite Wiesbaden; for the American there is every conceivable kind of Bethesda at a hundred different "Springs" in God's own country, but for the white in India, whatever his ailment, there are only the "hills." Well, there are hills at home too, and hills nearer home for the Londoner than the Himalayas. The man whose diurnal routine consists, largely, of a crowded rush amid a jostling mass of humanity flowing at 9.30 and ebbing at 5.30, and who is not deaf to the call in his heart's core, can be reminded of

> "The silence that is in the starry sky,
> The sleep that is among the lonely hills,"

and can in such an environment find time to readjust his values and learn there are other things in life than the clicking of tape machines.

And yet much depends on the make-up of the individual. One man's meat is another man's ptomaine. A scramble over the crags and through the bogs of Glen Sannox may be life-giving to one, and half-kill another. Ill-balanced enthusiasm for the long-looked-for holiday may result in one's going away for a change and having to come back for the rest. Caelum, non animum, mutant qui trans mare currunt. To send the claustrophobic to a shut-in valley, however delectable otherwise, and the agoraphobic to the moors and wide prospects of the uplands, is to court disaster; what is fascinating to the one may be appalling to the other.

Appropriate Choice a Fine Art.

Thus the choosing of a suitable holiday for our neurasthenic patients, an appropriate change of scene and occupation, is indeed a fine art. The individual has, in a sense, to be prepared if he is to obtain the maximum benefit from the change that is advised, and quiet counsel beforehand may prove of equal value to the actual break that is made in the tired life. A man may lose his taste for Nature, or he may, from a certain attitude of mind, fail to see and to assimilate the beauties that surround him. It was said of Huxley, I believe, that

> "Primroses by the river's brim
> Dicotyledons were to him,
> And they were nothing more,"

and if we have lost the child's gift of wonder we are in a bad way. We may be so accustomed to these very wonders of Nature that we never hear the waves beating on the shore, the ripples lapping in the reeds, never feel the winds or see the clouds for ever going over us. Yet to know once more that

> ". . . . . there, among the flowers and grasses,
> Only the mightier movement sounds and passes;
> Only winds and rivers,
> Life and death."

is to feel an uplift of mind and body which is worth all else put together.

When, then, we are asked as physicians to advise in the matter of recuperation and reintegration by recourse to a thorough change and genuine rest, it behoves us to consider the individual patient, his likes and dislikes, his present manner of living and working, his capacity for appreciation, his ability to absorb and put to use the effects of externals on him. And, when we have appraised the different factors, we must be decisive in our conclusion. We must know the very place for him, we ought and should be able, further, to speak from some personal experience of what we recommend.

As a Scot, I should be a sorry specimen of the breed were I to belittle the claims of the north, or attempt to deny that I seem to breathe a larger and sneller air once I cross the Tweed at Berwick. In our perfervid praise of the country that bore us we sing of other, benighted, scenes that

> "None of them can possibly surpass
> *Our* weather and *our* heather and *our* sea,"

we speak of *our* Scottish bluebells, as though all these were unknown in other less favoured regions. Yet the finest heather I have ever seen was in Holland, and bluebells beside which the Scottish variety pales are to be found in Swiss uplands. And some Southrons may tell us that we can keep our weather.

A Rest-Cure de Luxe.

A recent visit, longer than on former occasions, to Switzerland, has given me the opportunity of seeing and learning more of the possibilities of the playground of Europe, not from the viewpoint of winter sport but as a country where may be found in prodigal variety all that gladdens the heart of the lover of nature, and that can be utilised in the process of dispelling the fatigue and revivifying the sensibility of the routine-deadened brain-worker. It is possibly because Switzerland is, in some measure, but Scotland on a larger scale that it makes its appeal to myself. Apart, however, from personal considerations that are scarcely pertinent, that country offers abundant occasion to the neurasthenic of regaining health and strength, and, from communion with nature, of coming to view life in its proper proportions. I do not mean merely that to step out in the morning to breathe an air like wine, to feel on one's face a wind like that in a ship's rigging, cold and hard and pure, or to bask in a sunny valley in a paradise of flowers, soaking in warmth and sweet scents, is all that la belle Suisse offers. No praise of mine is required to add to what many have known and loved for years. But, speaking more technically, the neurologist cannot regard it as a mere coincidence that some of the greatest names in psychotherapy and the cure of neurosis are Swiss, and he may be assured that the place has produced the men and its attractions the material, drawn from sources innumerable. From all quarters, north, south, east, and west, the current not only of pleasure-seekers but of health-seekers sets towards Switzerland, and no one who knows the country and its opportunities is likely to admit the possibility of disappointment. There are resorts, set like gems in the crown of the Alps, where every kind of technical treatment for functional nervous disease is carried out, as in the best of private homes and hospitals, and where, in addition, the neurasthenic may lie on a balcony and feast his soul on a panorama that has few equals the world over, where the low-toned tinkle of cow-bells, the smell of a new country, the sights and sounds that are unfamiliar, may each and all make an appeal through his sense avenues to aid in the general effect and lead to the general cure. Shall I say that it is a rest-cure de luxe? Amid a comparatively recent and occasionally somewhat ultra-enthusiastic drive in the direction of the psychological aspect of disorder of nervous function we are apt, as it seems to me, rather to minimise if not actually to forget what cures were obtained before psycho-analysis was born, and rather to look askance at any methodological technique that does not include rummaging in old, unhappy, far-off things. For some cases this is material, for others it is more than ordinarily immaterial. The vendor of patent powders advertises over his shop-door, "Leave

Railway map showing direct routes from surrounding continental countries to the climatic health stations of Savoy and Switzerland. The position of three Alpine tuberculosis resorts is indicated by a figure in a square frame: 1, Montana-sur-Sierre; 2, Davos (via Landquart); 3, Arosa (via Coire).

whole year round but are only largely patronised in winter.

In the spas the baths and fittings are generally good, though without the magnificence of Harrogate and Bath. Baths, douches, and electrical treatment of all the recognised types are in general use. Several of the waters are hot; perhaps the advantage of being treated by naturally hot waters is, for the patient, mental rather than physical, but in a country where coal may cost £20 a ton, hot springs and water-made electricity are important. Leukerbad, one of the lesser winter sport centres, promises a natural hot bath to the devotees of sport when the day is done. The cold springs generally contain CO_2, so that one of the factors of Nauheim treatment is at hand. The springs are generally only feebly radio-active, but the waters of Disentis (at the top end of the Vorder-Rhein valley) and Baden are the most active.

The Upper Engadine (St. Moritz and Pontresina) with its fresh air affords an excellent after-cure both for patients who have undergone treatment at Tarasp in the Lower Engadine and also for patients who have completed sojourns at the spas of other countries.

The principal Swiss spas, then, may be classified as follows; in parentheses some of the corresponding spas in Great Britain or on the Continent are given:—

Sulphated waters.—Tarasp. (Cheltenham, Leamington, Marienbad, Karlsbad, Kissingen.)

Alkaline carbonated waters.—Passugg. (Cheltenham, Vichy, Ems.)

Carbon dioxide waters.—St. Moritz, Tarasp.

Iron waters.—St. Moritz, Tarasp. (Tunbridge Wells, Pyrmont.)

Arsenical waters.—Val Sinestra. (Levico, La Bourboule.)

Sodium chloride waters.—Rheinfeld, Bex. (Droitwich, Nantwich.)

Sulphur waters.—Baden, Gurnigel. (Harrogate, Strathpeffer, Aix-les-Bains.)

Simple thermal waters.—Ragaz, Leukerbad. (Bath, Buxton, Plombières.)

Individual Features.

The following notes are largely based on personal experience:—

Tarasp, 3900 feet, situated in the river gorge which runs along the wide valley of the Inn; well protected from winds and with small rainfall. Waters used for bathing and drinking. Two springs are purgative with sulphates, another contains iron; all are cold and contain much free CO_2. The hotels both here and at the contiguous Vulpera are good; the baths are excellent. Schuls, which lies close by and depends on the same waters, is less expensive. There are many graduated walks suitable for invalids and mild heart cases. Summer season only.

Ragaz, 1700 feet, in the canton St. Gallen, close to the Upper Rhine and near the Austrian frontier. The water, which is very abundant, is brought from Pfäffers, which lies in a ravine in the mountains; it is hot, 98° F., and has a very small amount of solids; it is mainly used for bathing. The baths are good and of many types, including thermal swimming baths. Summer season only and most suitable in early and late summer when the weather is not too hot.

Leukerbad (Loèche-les-Bains), 1600 feet, at the head of a side-valley off the Rhone, surrounded by high hills. The waters are abundant from several springs and hot; one has a temperature of 123° F. Both the baths and hotels are less luxurious than in many other spas, but the hotels are quite comfortable and the baths are adapted for the special type of bathing practised, the patients staying in the water for six hours or even more. The treatment is largely used for chronic itching diseases of the skin. Besides the summer bathing season there is a winter sports season, December to February.

St. Moritz, 6000 feet, the highest of the big health resorts, magnificently situated in the open valley of the Upper Engadine, formerly accepted tuberculous patients but now does not cater for them. In addition to winter sports, which are well known, it possesses iron and CO_2 waters which are hardly known enough, and the resort merits more recognition than it has received for convalescent cases. The waters are cold and the CO_2 springs are said to be the strongest in Europe. The hotels are numerous and luxurious and the baths well up-to-date. The baths are frequented June to returning to the lowlands should be refilled to a higher pressure than usual before leaving.

The complications of artificial pneumothorax and those cases where a pneumothorax cannot be produced owing to adhesions are more thoroughly treated by surgery than is generally possible at present in this country. Various types of thoracoplastic operation, and the filling of cavities otherwise impossible to close, by paraffin wax or by transplants of fat, seem to be the operations mainly performed. I did not hear of any special operations for the division of adhesions. Most of the sanatoriums have now their own operating theatre, and practically all their own X-ray plant.

Tuberculin seems to be now used in a somewhat attenuated manner, and rather in those cases "which are strictly localised, and when the patient is 'sticking' and not getting on," to use the phrase of Dr. Bernard Hudson of the Palace Hotel Sanatorium at Montana, than as a routine.

A general impression of the Swiss resorts for tuberculosis suggests that though there may be many cases which would do equally well in this country, there are others where the undoubted climatic advantages of the Alps, the well-equipped sanatoriums to be found there, and the therapeutic renown of the mountains, are of inestimable service.

METROPOLITAN ASYLUMS BOARD:
A COMPREHENSIVE REPORT.

To the annual report[1] for 1920 of the Metropolitan Asylums Board is appended a note on the constitution and duties of this Board which traces its history and development in succinct paragraphs. It was established in 1867, under an Act which empowered the Poor-law Board to combine into districts the unions and parishes of the metropolis for the purpose of establishing "asylums" for the reception of the sick, insane, or infirm. Successively under the control of the Poor-law Board and the Local Government Board, the Metropolitan Asylums Board is now composed of 73 members, of whom 18 are nominated by the Ministry of Health. The extension of its duties from the reception and relief of paupers suffering from fever, small-pox, or insanity (1867) to the present important and far-reaching activities has been gradual but continuous, and is a proof of the public confidence in the discretion of the Board. As regards infectious diseases alone, since 1911 the admission to the hospitals under certain conditions of non-pauper as well as pauper patients suffering from measles, whooping-cough, puerperal and other fevers, as well as those attacked by more classical infections, has effected an enormous change in the public conscience as regards the spread of infection. Moreover, under these newer regulations there is seldom a month when at least one of the hospitals under the control of the Board does not number a medical student among its patients, and the advantage gained is mutual. The instruction of medical students and of candidates for the D.P.H. is an important part of the work of these hospitals, and valuable public service is also rendered by the research and statistical departments. In connexion with the evergreen topic of the doubtful value of medical statistics unchecked by experts, a summary (p. 68) of the cases of mistaken diagnosis admitted into ten hospitals is of interest. Excluding the 45 uncertified cases and the 60 "admitted with mother,"—it seems somewhat harsh to include these in a table of mistaken diagnoses—there were altogether 2847 cases admitted in which the diagnosis was not confirmed on admission or after a period of observation; since the total number of patients admitted during 1920 was 35,916, the percentage of detected error is just under 8. The seasonal rise in infectious diseases started in the autumn of 1920 from a fairly high level, and in November, 1920, there were in hospital 8669 patients, 1511 more than the highest previous record. From present indications it is anticipated that a very heavy seasonal rise may be expected this year, and steps are being taken to prepare for this possibility.

Second only in importance to the work of the Board in providing segregation and treatment for patients suffering from epidemic and sporadic infectious diseases is its recently acquired responsibility for the treatment of persons suffering from tuberculosis. On May 1st, 1921, sanatorium benefit ceased to be included among those conferred under the National Health Insurance Act, and the duty of providing institutional treatment having devolved upon the county and county borough councils, the Board has entered into arrangements with the London County Council under which it provides residential treatment for tuberculous patients in the county. A total of 1664 beds for adults in sanatoriums and hospitals is being provided by the Board and 1317 beds for children, including 883 for children sent through the boards of guardians. Inasmuch as the available accommodation approximates to the requirements independently estimated by the London County Council, the Ministry of Health has decided that the proposed extension schemes shall not be proceeded with for the present. The education, training, and after-care of tuberculous children is receiving special and expert attention, and suitable provision is being made also for the training of adults.

The present scope of the work of the Metropolitan Asylums Board is so vast and the reports on its various activities so enlightening, that it is difficult to choose for comment any special section. The classification of mental defectives and their segregation in various institutions according to grades, the residential treatment of women and girls suffering from venereal diseases, the isolation of cases of ophthalmia neonatorum in a special hospital, and the efficient ambulance service are described, and the functions of the Board with reference to these and other responsibilities appear to be efficiently administered. The source of the boys admitted to the training ships *Exmouth I.* and *II.* is not made clear, and the classification of tuberculous patients on different principles in successive tables (pp. 23 to 30) is confusing. Among the medical records included as appendices is one by Mr. T. B. Layton on the otological work done at the North-Eastern and Western Fever Hospitals, to which we shall have occasion to return; it is unfortunate that the concluding section of this important report, containing recommendations now under consideration, has been omitted. But considering the mass of material dealt with, the annual report of the Board is informative without oppressive bulk, and regret can hardly be felt for the omission of a certain amount of matter, however interesting, which has enabled it to be issued in such convenient form.

GUY'S HOSPITAL BIENNIAL DINNER.—This dinner will be held on Oct. 26th at the Connaught Rooms, London. Mr. Montagu Hopson will preside, and tickets, price 15s., exclusive of wine, may be obtained from the hon. secretary, Mr. Arthur W. Ormond, 7, Devonshire-place, London, W. 1.

NORTH-EAST LONDON POST-GRADUATE COLLEGE.—The syllabus of a special post-graduate course, to be held at the Prince of Wales's General Hospital, Tottenham, from Sept. 26th to Oct. 8th, has been issued. Lectures on all aspects of medicine and surgery and the special branches will be given in the morning by members of the teaching staff of the hospital, and from 3 P.M. to 4 P.M. students will have access to the general hospital work. From 4.30 P.M. to 5.30 P.M. daily lectures on special subjects will be given by Mr. C. J. Bond, Dr. F. G. Crookshank, Mr. James Berry, Col. L. W. Harrison, Mr. H. W. Carson, Lieut.-Colonel W. Byam, Dr. Arthur Giles, Mr. H. D. Gillies, and Sir William Willcox; these lectures are free to all qualified medical practitioners. The fee for the course, to those not members of the Fellowship of Medicine, is 5 guineas, or 3 guineas for either week. Names of those wishing to attend should be sent, not later than Sept. 22nd, to the Dean at the hospital (or at 19A, Cavendish-square, London W. 1), or to the Secretary of the Fellowship of Medicine at 1, Wimpole-street, London, W. 1.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Salford.

THE annual report for 1920, by Dr. C. H. Tattersall, on the health of the county borough of Salford, extends to over 200 pages. With an estimated population of 235,239, the total number of births was 6441 (3282 males and 3159 females), equal to an annual rate of births of 27·3 per 1000—a decided increase from 18·3 in 1919—and the highest recorded since 1911. The death-rate is the lowest ever recorded, being 13·7 per 1000, which compares very favourably with 15·8 for 1919 and 16·8 for the five years 1913–17. The total deaths were 3133 (1646 males and 1487 females) and the excess of registered births over deaths was 3308. Special attention was given by the health committee to housing matters and to the two housing schemes at Lower Kersal and Weaste. The question of a central hot water-supply to the houses was abandoned on account of the greatly increased cost which would be entailed. The provision of shops on these two sites was included in the original plans, but up to the time of writing the Ministry of Health had not agreed to allow shops to rank for Government subsidy, and therefore the committee did not feel themselves justified in throwing the whole cost on the rates. The question of concrete houses was considered very carefully as a means of building economically, but the conclusion was arrived at that concrete houses, if properly constructed, would cost as much as brick-built. Electricity is to be installed for lighting and gas for cooking.

The erection of a new tuberculosis sanatorium, giving accommodation for 120 patients, has been commenced, and, it is hoped, will be ready for occupation in 1922. A scheme has been drawn up for providing 50 beds at Ladywell for female patients who require hospital as distinguished from sanatorium treatment. Scarlet fever and diphtheria have been more prevalent than during the past three years, but there has been no alarming epidemic. The conversion of the privy middens in the borough has been practically completed. A table is given showing the number of conversions made during the past 20 years and a comparison between the incident death-rate of enteric fever and epidemic diarrhœa respectively. In 1900 there were 23,000 privy middens, 7254 pail-closets, and 14,876 water-closets, the corresponding numbers in 1920 were 25, 800 and 49,206. As to enteric fever the attack-rate per 1000 living at all ages in 1894–98 was 1·80 and in 1916–20, 0·21; and for epidemic diarrhœa the death-rate per 1000 of population in 1894–98 at all ages was 1·70 and under 5 years of age 14·90, while in 1916–20 the corresponding numbers were 0·47 and 0·41.

Six cases of encephalitis lethargica were notified, but three of these turned out to be tuberculous meningitis. Forty-two cases of malaria were notified, of which 3 died; all the cases were found to have contracted the disease abroad. The total cases of syphilis treated were 680 and of gonorrhœa 606 at Salford Royal Hospital, and 260 of syphilis and 264 of gonorrhœa in outside institutions. In connexion with child welfare and supervision of midwives, 109 cases of ophthalmia neonatorum were notified during the year, 36 of these by the medical staff of the Royal Eye Hospital. Ninety-two cases occurred in the practice of midwives. In 52 cases both eyes were affected, and in 57 cases one eye only. Of the 109 cases, one died; 106 recovered completely with no injury to sight.

Ilford.

A large proportion of the inhabitants of the urban district of Ilford, with an estimated population in 1920 of 82,693, earn their living in London, which is only seven miles distant. The population is mainly lower middle class. There are a few industries: (1) photographic works; (2) paper mills; (3) manufacturing chemists; (4) electric battery makers; (5) nautical instrument makers. In the interests of efficient local government, a town of this size ought to have control of its own tuberculosis scheme, and midwives. The health statistics are satisfactory, as might be expected in a town like Ilford, the general death-rate is 9·0, the infant mortality rate 54, the rate for diarrhœa under 2 years per 1000 births is only 2·4, as compared with 9·5 for London and 8·3 for England and Wales. The death-rate from phthisis showed the usual rise during the war but for 1920 it was 0·50, the total death-rate from tuberculosis being only 0·69. A great improvement in the treatment of tuberculosis has been made during the past year by the institution of dental treatment for tuberculosis cases.

In 1919 Dr. A. H. G. Burton and the surveyor estimated that the council should provide at least 600 houses to meet local demands, and satisfactory progress has been made with four housing schemes, comprising 356 houses. In addition to this, the City of London have a scheme for 2400 houses on the Lonsdale estate, and the London County Council a scheme for 3200 houses at Dagenham, both in the Ilford district. Ninety per cent. of the diphtheria and 89 per cent. of the scarlet fever cases were treated in the Isolation Hospital. There has been some difficulty in obtaining nurses.

The infant mortality rate among illegitimate children was 230 and Dr. Burton is certainly justified in thinking that the supervision of foster children should be transferred from the guardians to the maternity and child welfare department, as suggested in the Ministry of Health's circular of Sept. 30th, 1919. Of the 90 deaths of infants, 45 occurred in the first four weeks of life. Two more health nurses have been appointed and overlapping is avoided and travelling time saved by these nurses performing the duties of health visitor and school nurse. Two antenatal clinics were opened during the year and a dental clinic is available for mothers and for children under 5. Ten cases of ophthalmia neonatorum were notified. In two cases the children were left with serious impairment of vision in one eye owing to corneal opacities. During 1920 169 women were admitted to the maternity home; the fee is two guineas per week, a portion being remitted when necessary.

Dr. Burton is also school medical officer and advocates great care before advising operation for tonsils and adenoids. "Most cases of enlarged tonsils are associated with carious teeth, which should first be treated. Many slight cases can be improved by suitable breathing exercises. . . . Further, the operation is by no means free from risk, especially when it is done, as is frequently, in an out-patient department, and the child allowed to return home the same day." Satisfactory arrangements are made for the treatment of minor ailments and the number of children seen at the school clinic has gone up from 962 in 1919 to 1763 in 1920. Of 4188 children inspected by the dentist, 3025, or 72 per cent., were found to require treatment. The report of the organiser of physical training points out the inadequacy of the swimming-bath accommodation.

Chelmsford.

The Registrar-General's estimate of the population of the borough of Chelmsford for 1920 was 21,666. The birth-rate was 20·8; the uncorrected death-rate was 11·9, the "corrected" 8·8. The infant mortality rate was 55·4 and the total tuberculosis rate 0·55. There were no deaths from infant diarrhœa. Dr. William J. Cox draws attention to the river pollution in the district. Under the heading "Maternity and Child Welfare," he mentions that "109 mothers (25 per cent.) suffered from carious teeth to a serious extent" and that in about 45 per cent. of cases no cot was provided for the baby. Overcrowding, he states, remains much the same as during 1919. "The conditions caused by overcrowding in this borough are undoubtedly serious." There are 120 houses calling for early demolition which cannot be dealt with your headache here," and as long as the consulting room remains true to its traditions it will similarly be the gateway to renewed mental and physical health for the neurasthenic, via Switzerland, Scotland, Skegness, or any place soever, provided its occupier has a knowledge of human nature and a lore not gained from books.

III.—SWISS HEALTH RESORTS FOR TUBERCULOSIS

BY A. NEVILLE COX, M.D. LOND., M.R.C.P. LOND.,
TUBERCULOSIS OFFICER, BRIGHTON

THE Swiss health resorts fall into two classes: (a) those which cater for patients suffering from tuberculosis, and (b) those which do not accept such patients. This arrangement has manifest advantages. The non-tuberculous invalid has no grounds for the fear, however unreasonable such a fear might be, that he runs risks of infection from other patients; and the consumptive has the satisfaction of knowing that he is among his kind, and that he is not shunned by others. It is not suggested, of course, that none but consumptives go to the tuberculosis resorts. That is far from being the case, and indeed several of these resorts attract healthy winter sport enthusiasts in large numbers. Some hotels at Davos and elsewhere do not accept invalids, and in some others a part of the hotel is reserved for the healthy visitors.

The Climate and its Advantages

All these tuberculosis resorts enjoy great advantages of altitude, abundant sunshine, and pure atmosphere. It is difficult to judge which of these factors is the most important, but it is undeniable that the combination of them produces remarkable improvement in cases of phthisis of the right type. It is obviously futile to send to the mountains consumptives with advanced progressive disease, intestinal ulceration, great dyspnœa, cyanosis, and the like grave symptoms. Hæmoptysis, on the other hand, is no contra-indication. Laryngeal cases also do well, if the pulmonary lesions are not too severe. Sanatorium physicians in Switzerland, as elsewhere, complain that patients are frequently sent to them too late.

It is not considered necessary for the patient, unless he is much enfeebled, to do the journey in easy stages as was formerly recommended. Arosa is now easily reached from Chur by electric railway, which takes the place of the old six-hour journey by diligence. Montana, similarly, is now connected with Sierre on the main Simplon line by funicular. Davos is reached from Landquart by the Rhaetian railway. Each of these places has its special attractions. Arosa lies well sheltered and delightfully among its wooded mountains. Montana is perched 5000 feet up on a plateau on the north side of the great Rhone valley, facing due south a grand distant panorama of Alps. It lies just within the French-speaking part of Switzerland. There is a sanatorium staffed by English doctors and nurses, and for the healthy there is the attraction of a fine golf course. Davos in its valley is quite different from both, but has a charm of its own. It has also the advantage, from the point of view of some patients, of possessing the shops and social amusements of a considerable town. Each of these places has its enterprising 'Kurverein,' which is ever ready to supply information to intending visitors, and does valuable work in developing the amenities of the place. At Davos, for instance, the damage done by the avalanche of a recent winter has been repaired, and steps have been taken at great expense to prevent the risk of similar accidents in the future.

Equipment and Outline of Treatment

Many of the great Swiss sanatoriums, even of those known as the "popular" sanatoriums, are planned on a lavish scale. This of course can be overdone, and is by no means essential to good treatment. But the ideal of extreme simplicity can also be overdone, and it is possible that in some cases in England cheapness in buildings and equipment is associated with cheapness in more important matters.

In regard to treatment at the Swiss sanatoriums one is struck by the amount of individual supervision of patients. Each patient is usually seen by the doctor twice daily, and, of course, oftener if he is seriously ill. The hours of rest and the amount and times of exercise are all laid down for strict observance. All this is implied in the general term "Kur." It is perhaps an unfortunate word, since it suggests that very different thing, the anatomical cure of the disease. When we hear of a patient coming for the "cure" several years in succession, it sounds like a contradiction in terms. May it not be the lack of this constant and careful supervision in some of our English institutions which has brought the whole system of sanatorium treatment into some disrepute among us of late? Genuine sanatorium treatment in the average case is nothing more or less than an unremitting attention to every detail of the patient's life, an attempt to eliminate as far as possible every adverse influence retarding recovery, and promote every favourable influence assisting it. This is not an art to be acquired in a few months, yet we frequently see medical appointments at our English public sanatoriums advertised at salaries which cannot possibly attract good men for long. Often, too, it is stipulated that applicants shall be unmarried.

In Switzerland much more importance seems to be attached to rest than to exercise, and the method of graduated labour does not appear to be in vogue. Walking is generally regarded as the best form of exercise. There is sometimes a difficulty in restraining the more energetic patients from taking too much part in winter sports, most of which are obviously unsuited. For the ambulant patients about five hours' rest daily, lying on long chairs on the balconies, seems to be the rule. Rest before meals is insisted on; rest immediately after meals is not encouraged, and it is thought better at those times to take a little walk. From two to four each afternoon is in many places kept as a time of complete rest, with no talking, reading, or any occupation whatever. Patients on admission are kept for about a week in bed, and if the pulse and temperature are satisfactory, are then allowed to begin getting up. The method used in some American sanatoriums of keeping even afebrile patients in bed for six to eight weeks does not seem to be practised.

Special Methods

Heliotherapy is everywhere condemned for pulmonary cases except for certain chronic pleurisies, which it relieves. In the ordinary pulmonary case it is said to cause "congestion" and to provoke hæmoptysis. This apparently is not the experience in some of the Scandinavian sanatoriums; one author there states that the incidence of hæmoptysis in his institution has strikingly diminished since actinotherapy was started. In surgical tuberculosis heliotherapy is, of course, extensively used with excellent results when properly applied. No more than a drug like digitalis can sunlight, whether real or artificial, be used in treatment with success if employed indiscriminately and without proper regard to dosage and idiosyncrasy. Dr. O. Bernhard, of St. Moritz, a pioneer in the scientific application of sun treatment, has summarised his experience in a recent article in *Tubercle* (August, 1921).

Of the more specialised forms of treatment, artificial pneumothorax is everywhere in considerable use, and is probably applied in a wider range of cases than is at present customary in England. At one sanatorium I was told that some 12 per cent. of cases are found suitable for this treatment. As a main indication, assuming a unilateral lesion, definite evidence of breaking down or cavitation of lung tissue shown, for instance, by the presence of elastic fibres in the sputum, was suggested to me. Patients in whom a pneumothorax is already established should go to the mountains just before a refill is due, so that the change in atmospheric pressure is not harmful; similarly, on

THE NATURAL HISTORY OF ENCEPHALITIS LETHARGICA.

To the Editor of THE LANCET.

SIR,—In regard to encephalitis lethargica I have a theory which I should like to put before the medical profession for their careful consideration, believing that if it stands the test of criticism and turns out to be true it may prove of considerable value. During the year 1918 I saw some 12 cases of this disease; they occurred mostly during the first three months of the year. Most of them were severe cases and very typical; about half of them died, and of those who survived one eventually found his way into an asylum, one took to drink, and one, a lad, became feeble-minded. A fourth, a child of about 8, still suffers from headaches, and is unable to make any progress at school or to get on happily with other children. In this year the disease was not a notifiable one, consequently statistics are not available. In 1919 I can only remember to have seen 4 cases; of these two died and two recovered, but one, a year later, was reported to be unable to attend school owing to headaches. Four other cases were reported. In 1920 I saw 3 cases, one of which was in December, but 7 others were reported to the Ministry of Health, making 10 in all. This year I have seen 12 cases and one other in which the diagnosis was somewhat doubtful; 11 others have been reported to the medical officer of health; one at least of these was doubtful. They mostly occurred in the first three months of the year and were then milder in character, but in June and July there were some fresh cases, and these were more severe ones. Those I have seen this year have conformed less to the type originally described than did those of 1918. These cases have been scattered all about the county. With the possible exception of the south-east corner, which I see but little of, no large area of the county seems to have been without one or more cases, yet hardly any case seems anywhere to have arisen in close proximity to any other case. They have occurred amongst rich and poor alike, and in remote country cottages and farms more often, I think, than in towns. The only point I would note, taking the four years together, is that an unduly large proportion have occurred amongst those whose work is connected with the railways.

All this suggests that the infection is very widely distributed. What are the connecting links between the cases? The two most probable suppositions are: (1) That the infection is spread by carriers—i.e., human carriers, who do not themselves show any symptoms of illness. (2) That there is a very widely spread and fairly common disease in our midst which only very rarely affects the central nervous system, just as tubercle only very occasionally causes meningitis or cerebral tumour. I believe the latter supposition to be the correct one. It certainly would account for the peculiar distribution of the disease far better than any other that has been suggested.

Now there has been this year another set of cases occurring in Shropshire very commonly, I believe, characterised more or less clearly by the following signs and symptoms.

1. Fever, sometimes sudden, sometimes gradual, or even insidious in its onset, of varying type, uncertain duration, and prone to recrudesce.
2. Sore-throat of a peculiar character.
3. Gastro-intestinal disturbances—generally vomiting and diarrhœa.
4. Broncho-pneumonia, with sharp crepitations at the bases of the lungs.
5. Often an erythematous rash on the body and legs, chiefly in the form of large red patches, but varying greatly and of short duration. This is by no means always noticed, possibly because of its transient nature and because it is not looked for.
6. Marked prostration and slow recovery.

The throat is characterised by slight swelling but very marked congestion of the fauces and pharynx; the colour is generally a deep crimson, but sometimes is almost vermilion. There is comparatively little swelling of the tonsils, but whitish patches of exudation are to be seen on tonsils, fauces, and pharynx. These patches sometimes look very like diphtheritic membrane and occasionally can even be stripped off, but in none of the cases has the specific organism of diphtheria been found. These throats tend soon to become dry, and are often associated with a red, bare, swollen, and dryish tongue. Curiously enough, the patients complain very little of any pain, and unless the fauces are very carefully examined the presence of the "sore-throat" is apt to be overlooked; the patients more often come before one as cases of gastro-enteritis or broncho-pneumonia than of tonsillitis. It is, I think, a very infectious illness, though often seen in much slighter forms in other members of the household.

Now I have seen a similar condition of throat in a number of the cases of encephalitis, and have pointed it out to my medical colleagues—sometimes even telling them beforehand that I expected to find it; but I think it has only been in those which I have seen in the early stages. I have also found symptoms of gastro-enteritis and broncho-pneumonia in these cases, and often albuminuria. I was particularly struck by its appearance in my women's ward at the Royal Salop Infirmary at a time when I had a typical case of encephalitis lethargica there. Two very well marked cases occurred; one was in a strong, healthy, hysterical girl who had been in for some weeks previously and who became very ill with it. The other was an elderly woman suffering from heart disease who had been in for many weeks and was at the time slowly recovering. She developed this illness and very nearly died from it. It was especially noteworthy that she made very little mention of any pain or soreness in the throat, though it was very markedly congested and unhealthy looking. We had a good many slighter cases of sore-throat in the ward. None of them showed any symptoms of encephalitis, but it was the fact that the patient with encephalitis had a similar condition of sore-throat when first admitted that made me suspect that she might have been the original source of the trouble.

Another case seen near Newtown, in Montgomeryshire, impressed me greatly. A country gentleman, aged 60, who led a very healthy, active life was suddenly smitten down after a day's hunting with a very severe illness, characterised by high fever, sore-throat, and intense headache, the pain being most severe behind the right eye. The glands of the neck were enlarged and tender; there was marked redness and slight swelling of the face, and a transient erythema on the body and limbs. The throat was a very marked example of the condition I have tried to describe, and showed the typical white patches of exudation. When I saw him he had broncho-pneumonia, with sharp crepitations at the bases; he also had gastro-enteritic symptoms, and his liver was palpable and slightly tender. He was certainly very acutely ill; but he was slowly beginning to show signs of improvement, when on the fifteenth day of his illness he had a rigor, the temperature ran up to 104° F., his face became ashy grey and sunken-looking, and his breathing became of the Cheyne-Stokes character. He became first drowsy, then more and more comatose, and he died three days later. This seemed to be a case of encephalitis lethargica in which the stress of the disease had fallen chiefly upon the medulla rather than upon the mid-brain or cerebrum, and it certainly began as a typical but very severe case of the illness which I have been trying to describe.

The theory which I wish to put forward is, therefore, that we have a very widespread disease in our midst, which is itself new in character, which is markedly infectious and therefore tends to be fairly common, and which occasionally attacks the higher nervous system and especially the mid-brain, producing the symptoms to which we have given the name of encephalitis lethargica. I think it is quite possible

Public Health Services.

SCHOOL MEDICAL SERVICE.

Sheffield.

Dr. Thomas Chetwood reports that the routine medical examination of 24,488 children showed 22·5 per cent. of them to require treatment. Sheffield would appear to be a health resort for children, since only 3 per cent. were noted as anæmic and 2 per cent. as rickety. Yet the average height in the elementary schools, which may be taken as an indication of the whole past history of the child, is below standard, and the average of weight, which reflects present conditions, is still more below standard. Conversely the secondary schools are well above the usually adopted standards. These averages as given for the largest groups comparable are interesting enough to reproduce here.

Age in years.	—	Boys.		Girls.	
		Height.	Weight.	Height.	Weight.
12	Elementary schools	137·21	31·94	138·48	32·23
	Secondary ,,	143·05	34·75	144·10	35·01
13	Elementary ,,	141·47	33·45	142·42	35·07
	Secondary ,,	146·19	37·56	148·40	38·83

Excellent and detailed work is recorded in every department; only the notes on "school hygiene" are perfunctory and not quite worthy of the rest of the report. Here surely in this great University city there might be coördination with the University, which is an untapped source of enthusiastic workers ready for training and experience. 25 per cent. of the children had sound teeth, 44 per cent. having less than four teeth decayed. 11 per cent. had nutrition under average, 0·5 per cent. being classified as bad. During the year 176,000 school dinners, 189,000 breakfasts, and 97,000 teas were served in school and feeding centres. The employment of a few more dental dressers, in addition to three dental surgeons, should ensure an excellent dental service. 10,858 children out of 12,784 examined were found to require dental treatment, and of these 4874 obtained it. One-seventh of the cases were cured with an average of five attendances. The two open-air schools by means of which Sheffield helped to educate this country are reserved for ailing children. There are no classes for dull and backward children, and no nursery schools.

Excellent reports are given of the school baths, each of which serves 4000 children weekly. Swimming is taken as a physical exercise in the public baths. It has been found that in the douche bath rooms, unless the hoppers of the windows are open outwards instead of inwards the valve-like action prevents the rising steam escaping. The report calls attention to another risk of bathing, as does Dr. Dan McKenzie in our correspondence columns.

> "Several cases have occurred during the year of serious infection to the nose and ears in children attending the swimming baths. The danger of this infection is mostly to children who already have some discharge either of the ears or the nose. It has long been recognised that the entrance of unsterilised water into the ears in cases of otitis media constitutes a grave danger. That this is so in cases of nasal discharge is not so generally recognised, but it is fully as important."

A good analysis of loss of attendance from various causes shows coughs, colds, and bronchitis as responsible for 30·4 per cent., infectious disease 10·1, contagious disease 6·7, sore throats 3·8, debility and anæmias (which last we have already seen is so rare) 3·6 per cent.; illness in the home 4·5 per cent., chiefly in the girls' department. "This is not to be wondered at, when the figure given for illness of mother is as high as 3·4 per cent." Of possible attendances 13 per cent. were lost.

Northampton.

The Northampton authority is to be congratulated on a live and heartening report, which shows a breadth of view and a grasp of essentials deserving close attention. Dr. G. H. Skinner gives a general survey of school hygiene, showing still existent small diamond-shaped windows, long desks with seats without backs, and 92·0 per cent. of 5-year-old children unvaccinated. Attention is drawn to the necessity for what is called individual ventilation—a single desk for each child, so that a definite free air space of several inches is ensured for each. No defect treated has been counted twice, nor has any unremedied defect been counted over again during the period in which it remains unremedied. The census of cripples showed 10 per cent. under school age. Dealing with dental decay, the report urges:—

> "It must be borne in mind that the toothbrush used indiscriminately in a septic mouth acts as a spreader of disease, and by friction may convert chronic inflammation into the acute form; this might promote healing had the cause of sepsis been removed, but might have serious results if it had not; and on this account I am of opinion that toothbrush drill in school may prove to be a mixed blessing. . . . Fortunately, on account of the diffusion of knowledge as to the importance of cleanliness of the teeth it is not so necessary as it may have been in the past. All attempts at food reform must come to naught as far as school children are concerned unless the teeth are put in such a state that mastication is painless, and reform will then be a natural consequence in most cases, as the human being, like most mammalia, has always shown a desire to exercise his teeth upon resistant substances unless hindered by unnatural conditions which prevent him obtaining the mixed diet to which his teeth are suited. By treating incipient decay at the earliest possible opportunity with silver nitrate, most infants would present, and by subsequent supervision would retain, at least a fairly satisfactory milk dentition, which would not contaminate the permanent teeth, would preserve the space for their successors, and would enable the child to masticate more solid food. Otherwise slops must be given or the solid food is bolted; one tender tooth will throw out of action the whole masticatory apparatus."

It is also pointed out that dental treatment of children under 5 would probably enable a dentist to overtake 10,000 children instead of 5000 as at present.

Successful arrangements have been made for the treatment of speech defects. Two experimental nursery classes have been established as a preliminary to a nursery school. The transference of the X ray work to the school clinic has resulted in the number of ringworm cases at the end of the year being the lowest recorded. The total number of ear defects requiring attention was 429, and of that number 261 received treatment at the school clinic, with an average of 18 attendances, 52 per cent. being cured. Altogether 5515 routine and 3734 special examinations were made, and of these 4118 children were found to have defects, the number of defects requiring treatment being 6126; 91 per cent. of these obtained treatment, and 70·6 per cent. were cured.

In its grasp of essentials and its curtailment of non-essentials this report reaches high-water mark.

Nuneaton.

The number of children examined at routine inspection was 2035. Of these, 29 per cent. were found to be vaccinated, as compared with 43·3 per cent. in 1919. Of the girls in the 13 senior departments, 57 per cent. had verminous heads. The term verminous is rightly applied to children with one or more nits or pediculi in their heads; consequently the percentage is higher than in most school medical officers' reports. There are no nursery schools, no school baths, and no voluntary body exists except the Society for the Prevention of Cruelty to Children. 30·6 per cent. of 2035 children were found with perfect dentition. The arrangements for the treatment of ringworm with X rays should result in a marked diminution in the number of cases of this disease, which is at present too high. Arrangements for building a cleansing station for the treatment of scabies are in hand.

Dr. Middleton Hewat reports that every school in this area has a playing field, and every crippled child suspicious case of diphtheria in a house in the poor industrial part of the town. I gave antitoxin, which the M.O.H. authorised me to purchase, and sent the bill in to the local council, which after discussion refused to pay, informing me that I must collect the money from the patient. The same week they refused to pay for antitoxin given by another practitioner for a similar case.

I give antitoxin for two purposes: (1) the benefit of the community, and (2) the benefit of the patient. If the local authority refuses to provide antitoxin, I endeavour to collect the cost from the patient; if I fail to do so, I then have to pay out of my own pocket for treatment which benefits the community. If this state of affairs is allowed to continue my dosage of antitoxin will depend on the length of the patient's purse or of my own. The suitability of patients for free antitoxin is surely a matter which must be left to the practitioners who enter the homes and know the circumstances of each case.

On placing the case before the Ministry of Health a letter was written to the council and elicited the reply, "that the case was one in which the council did not consider they should be called upon to provide antitoxin." The Ministry then informed me that they could do no more.—I am, Sir, yours faithfully,

August 28th, 1921. B. L. S.

THE GROSVENOR TELEPHONE EXCHANGE:

MEDICAL MEN'S NEW NUMBERS.

THE new Grosvenor exchange, opened on Sept. 3rd, at 39, South Audley-street, London, W. 1., involves the transfer of a number of medical subscribers from the Mayfair exchange. The new exchange lies within the 5-mile circle from Oxford Circus, and therefore within the local fee area of all exchanges within a radius of 10 miles from Oxford Circus. Arrangements have been made to transfer calls made for the old numbers with as little trouble and delay as possible, the callers being advised of the change in each case. We give a list of the names transferred from Mayfair to Grosvenor, and take the opportunity of adding a further list of intended transfers from Mayfair to Langham.

Transfers from Mayfair to Grosvenor. (Below the dividing line to take effect on Sept. 17th.)

Medical News.

FREE MILK IN INFANT WELFARE CENTRES.—The value of infant welfare centres has been considerably enhanced during the past few years by the supply of free milk to expectant mothers in the later months of pregnancy, to nursing mothers, and to artificially fed infants up to the age of 5 years. 50 per cent. of this expenditure has been met hitherto by a grant from the Ministry of Health. The decision to reduce this grant considerably is doubtless in response to the well-recognised need for economy in national expenditure. An adequate supply of milk is essential for expectant and nursing mothers and for artificially fed infants, and any measure that interferes with this supply is to be deplored. On the other hand, there is a possibility of abuse of this grant, and it is of the utmost importance that the milk should be granted only to deserving cases. It is to be hoped that by exercise of a vigorous scrutiny the welfare centres will be able to continue their valuable work, despite the proposed reduction in the State grant, and that at the same time the prospects of health of the next generation will not be impaired.

EPSOM COLLEGE.—Several exhibitions will shortly be awarded to the sons of such duly qualified medical men as shall in the opinion of the Council of the College be among the less fortunate members of their profession. Holders of these exhibitions pay only 50 guineas a year instead of the usual fee of 100 guineas. "France" pensions of £30 a year will also be awarded to several medical men not under 55 years of age, whose income, independently of any allowance from the College, does not exceed £100 a year. Forms of application can be obtained from the secretary, Mr. J. Bernard Lamb, 49, Bedford-square, London, W.C. 1.

THE death is reported on Monday from Rhosneigr, Anglesey, of Thomas Arthur Helme, M.D., F.R.S. Edin., M.R.C.P. Lond., consulting physician to the Northern Hospital for Women and Children, Manchester.

THE LATE DR. R. W. ALLEN.—Richard William Allen, M.D., B.S. Lond., who died on August 28th, was a native of Auckland and graduated M.A. New Zealand from Auckland College. He then had a distinguished academic career at Guy's Hospital. Formerly pathologist to the Royal Eye Hospital he became interested from the first in vaccine therapy, directing this department at Mount Vernon Hospital, and editing for a time the *Journal of Vaccine Therapy*. His book on Vaccine Therapy: its Theory and Practice, ran into four editions, and he was the author of a larger work on the Bacterial Diseases of Respiration.

THE LATE DR. A. J. MACCALLUM.—Alexander John MacCallum, who died in a nursing home at Aberdeen on August 23rd, was a native of Keith, Banffshire, and took his degrees of M.B., C.M. at Edinburgh in 1891, becoming F.R.C.S. Edin. in 1902 and M.D. in 1908. He practised at Kendal, and was particularly interested in epilepsy, being for some years physician to the Staruthwaite Epileptic Colony. A magistrate for Kendal, and for some time a County Councillor, Dr. MacCallum had many interests outside his busy professional life, and his death at the early age of 54 removes a figure well known throughout Westmorland.

THE LATE DR. ALFRED MACPHERSON.—Dr. Alfred Macpherson, the oldest practitioner of Uitenhage, Cape Province, died there on August 4th, after an illness of three months. He was one of the leading men of the district, having taken an active interest in educational, political, and other public matters. Dr. Macpherson, though he had refused all invitations to stand for election to the House of Legislative Assembly, was the leader of the local branch of the Unionist Party (now amalgamated with General Smuts's South African Party). Dr. Macpherson was educated at the University of Edinburgh, where he graduated M.B., C.M. in 1880. He leaves a widow, one son, and three daughters.

THE LATE DR. T. H. MORTON.—Thomas Henry Morton, who died at his home at Nether Edge, Sheffield, on August 26th, in his 83rd year, was the doyen of the medical profession in the city. He became M.R.C.S. Eng. in 1861, L.S.A. in 1862, L.R.C.P. Irel. in 1874, and M.D., C.M. Aberd. in 1876. At one time President of the Sheffield Medico-Chirurgical Society he practised in Sheffield throughout his professional life, and was held in grest esteem by the workpeople. Although he had retired from practice for many years Dr. Morton remained a well-known figure on account of his wide interests, which included furniture, archæology, numismatics, ornithology, and photography; he was also keenly interested in politics and active in Church affairs.

owing to the acute shortage At the present time there is a waiting list of about 600 applicants for new houses under the corporation scheme The scheme, it seems, has been much hindered by the difficulties of obtaining building materials

Herefordshire

Dr Herbert Jones's report on the Herefordshire Combined District for 1920 covers the rural districts of Bromyard, Dore, Hereford, Ledbury, Leominster, and Weobley, and the urban district of Bromyard The estimated population of the 6 rural districts for 1920 was 47,086 The birth rate was 25 2, compared with 17 5 in 1919 The death rate was 13 5, the infant mortality rate 60 and the phthisis death rate 0 80 An endeavour is being made to pool the infectious hospital accommodation of the districts and that of the city of Hereford in the interests of efficiency and economy

Dr Jones reports on many primitive sanitary conditions such as cottages draining into road side ditches, obsolete forms of drain traps, and dip wells liable to pollution At the end of the report is a valuable leaflet on the economical construction of earth closets The combined district is just the area for their employment and it is disappointing that so few people living in the country have as yet taken the trouble to master the simple principles necessary for the maintenance of a sanitary closet In 1871, the State Board of Health of Massachusetts issued a report strongly recommending the earth closet as a substitute for that disgrace to civilisation, the country privy Dr W Ramsay Smith, head of the South Australian Public Health Department advocates them in a report published this year As Dr Jones says "Wherever there are a few perches of garden attached to a house it is possible to replace a foul smelling dangerous privy closet by a harmless inodorous earth closet" The public in general fails to appreciate the deodorising and purifying effect of earth suitably applied No stinking privy should be dignified by the name of earth closet Dr Jones's leaflet has been separately published by the *Medical Officer* and merits a wide circulation in country districts

IRELAND

(FROM OUR OWN CORRESPONDENT)

Irish Labour and the Public Health

IT is a healthy sign that in spite of the distracting elements in Irish public life at the present moment, all parties are showing an intelligent interest in the public health Under the auspices of Dail Eireann several of the local health authorities have been putting forward schemes of reform of the Poor law and Public Health Services which show evidence of careful consideration And now labour is devoting its attention to the same subject At the recent meeting of the Irish Trades Congress in Dublin the following resolution was unanimously passed —

> "That the National Executive be instructed to draw up for the benefit of Labour members of local authorities a comprehensive scheme of Public Health Service reforms towards the attainment of which all Labour members of local authorities could use their influence

In their deliberations the national executive of the Trades Congress should gain much help from a study of the report of the Irish Public Health Council

Cancer Research in Dublin

Ireland's high death rate from cancer is well known A concerted effort is being made to raise a sum of money to provide more adequate accommodation for cancer patients in the City of Dublin Hospital and to establish and equip a research department in connexion therewith The committee formed in London to assist this Cancer Research Fund has Mr J McVeagh M P, as its chairman and Mr Frank Spicer F R C S I, as hon secretary with an address at 58 Warwick street, S W

Household of the Lord Lieutenant

The following medical appointments have been made to the household of His Excellency the Lord Lieutenant of Ireland —Physicians in Ordinary E McD Cosgrave F R C P I, Sir James Craig, M D Surgeons in Ordinary Sir F Conway Dwyer, F R C S I, E H Taylor, F R C S I Physician to the Household Sir John Lumsden, M D K B E Surgeon to the Household Sir W I de C Wheeler, F R C S I Surgeon Oculist, H C Mooney, F R C S I

HYDROCYANIC ACID AND SANITATION

To the Editor of THE LANCET

SIR —An annotation in your issue of July 16th (p 116) refers to recent legislation in the *United* States, Italy, and Sweden on the use of hydrocyanic acid for *fumigation* of shops and buildings, based upon an article in the May issue of the *Office International d'Hygiene Publique* May I say that throughout South Africa this method is very commonly used for the destruction of bugs From time to time there have been an appreciable number of *fatalities and, as regards Johannesburg and several* of the Reef towns this was specially the case in the years immediately preceding 1913 In Simonstown some years ago a pigeon fell dead while flying past a window broken with a stone to permit the egress *of the gas after disinfection*

As our statutory list of offensive trades' includes charcoal burning and lime burning with which for this purpose cyanide *fumigation is sui generis I* recommended its addition to the list of such trades and the adoption of stringent controlling regulations This proposal was turned down as ultra vires by the then town clerk, but was eventually entirely upheld by the Government law advisers, and in January, 1916 regulations were *adopted Briefly*, these provide for the licensing of such disinfectors, for the safety and supervision of their methods, for 24 hours written notice *of intention* to disinfect (*a*) to the M O H, (*b*) to the occupier of the premises concerned, (*c*) to the occupants of any adjoining house unless *separated* by a *minimum* open space of 50 feet, for the evacuation of all apartments on the same or any upper floor for putting out of fires and removal *of all liquid or moist foods*, *for effectually* closing or caulking all openings and crevices in the room under disinfection for closing and locking it from the outside and placing upon it a conspicuous danger placard and for opening the windows from the outside at least one hour previous to entry *after disinfection* Every disinfector must be equipped with aromatic spirits of ammonia and with brandy, must be competent to apply *artificial respiration*, must *dispose* of the cyanide residue in such a way *as to* obviate danger therefrom (this is very important), and must keep under lock and key any cyanide stored *by him* Basements cellars &c which do not possess a door, window *pavement light, or hatch opening* directly to the outside air must not be *disinfected* with cyanide

These stringent regulations were at first resisted or ignored but as the *danger* was very generally recognized in Johannesburg, a number of prosecutions with heavy fines quickly brought the disinfectors to heel, and the results up to date have been quite satisfactory I may add that when framing these *regulations* I was unable to find any *other code* dealing therewith but derived assistance from an article by Dr Howard of the United States Department of Agriculture (*Bureau of Entomology*— Circular No 163 Nov 20th, 1912) Our regulations have now been widely adopted verbatim, throughout the Union —I am, Sir, yours faithfully,

CHARLES PORTER

Aug [illegible] 1921 Medical Officer of Health Johannesburg

Queen Mary's Hospital for the East End, Stratford, E.—Cas. O. £150.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—H.P.'s. £100.

Rotherham Hospital.—Jun. H.S. £150.

Royal Free Hospital, Gray's Inn-road, W.C.—Cas. O. £100. Clin. Assts.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.S. £100.

St. Mary's Hospital Medical School, Paddington, W.—First, Second, and Third Asst. in the Med. Clinic. £750, £450, and £350 respectively.

Saint Pancras Dispensary, 39, Oakley-square, N.W.—Hon. Phys.

Salford Royal Hospital.—Res. Surg. O. £250. H.P. £200. H.S. £150. Cas. H.S. £150.

Salisbury General Infirmary.—H.S. £200.

Sheffield, East End Branch of the Children's Hospital.—Female H.S. £150.

Sheffield Royal Hospital.—Cas. O. Asst. Cas O. Each £150.

Sheffield Royal Infirmary.—Asst. Cas. O. £150. H.S. for Ear, Nose and Throat. £150.

Sunderland Royal Infirmary.—H.S. £200.

Tunbridge Wells General Hospital.—H.S. £160.

West London Hospital, Hammersmith-road, W.—Two H.S.'s. H.P. Each £100. Surgeon.

Westminster Hospital, Broad Sanctuary, S.W.—Cas. M.O. £50. Temp. Cas. O. 50 gs.

Wolverhampton County Borough Education Committee.—Asst. Sch. M.O. £600.

Wolverhampton, Wolverhampton and Staffordshire General Hospital.—Res. M.O. £200.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at: Hoo (Kent); Knottingley (York, West Riding); Preston, West (Lancs.); Stevenage (Hertford); Catrine (Ayr); Carnoustie (Forfar).

The Home Secretary gives notice of a vacancy for a Medical Referee under the Workmen's Compensation Act, 1906, for the Sheriffdom of Forfar. Applications for the post should be addressed to the Private Secretary, Scottish Office, Whitehall, S.W. 1, and should reach him not later than Oct. 1st.

Births, Marriages, and Deaths.

BIRTHS.

BETT.—On August 23rd, at Haslar, the wife of Surgeon Rear-Admiral William Bett, M.V.O., R.N., of a son.

CAPLAN.—On August 28th, at North End-road, West Kensington, the wife of Samuel Caplan, M.D., of a daughter.

FOULKES.—On August 29th, at Nelson-street, King's Lynn, the wife of Peter Gifford Foulkes, M.B., B.S. Lond., of a son.

HAWARD.—On Sept. 2nd, at the Wold, Woldingham, Surrey, the wife of Walter Haward, M.B.Durh., B.S., of a son.

HEFFERMAN.—On August 29th, at Namtu, Burma, the wife of L. W. Hefferman, M.R.C.S., L.R.C.P. (Joan Godfrey), of a daughter (Pamela Dorothy). (By cable.)

HOSKIN.—On August 29th, at Sheffield-terrace, Campden Hill, W., the wife of T. Jenner Hoskin, B.Ch.Camb., M.R.C.P.Lond., of a daughter.

MONTGOMERY.—On August 24th, at Beaumont-street, W., the wife of V. C. Montgomery, M.B., Ch.B.Belf., of a son.

PERN.—On August 28th, at Hildegarde House, Whitby, the wife of L. Pern, M.R.C.S., L.R.C.P.Lond., of a son.

PURCHASE.—On August 29th, at Warwick Mansions, S.W., the wife of Dr. W. Bentley Purchase, Barrister-at-law, of a daughter.

MARRIAGES.

FRANKLIN—WEIR.—On Sept. 1st, at St. Columba's (Church of Scotland), Pont-street, the Rev. Foster Franklin, M.A., Minister of the Parish of Kimlacolm, Renfrewshire, to Mary MacLean Weir, M.A., M.B., Ch.B. Glasg., daughter of Mr. and Mrs. John Weir, Catford.

GREVILLE—MOWAT.—On Sept. 3rd, at St. Andrew's Church, Frognal, Gordon Greville, M.R.C.S. Eng., L.R.C.P. Lond., to Marjorie Scott, daughter of the late Robert Mowat and Mrs. Mowat, Edinburgh.

MACKIE—COLLINGWOOD.—On Sept. 1st, at Yateley Church, George Mackie, D.S.O., T.D., M.B. Edin., to May Campbell Carnegie Collingwood.

WALLIS—ROFFEY.—On Sept. 1st, at St. Swithin's Church, East Grinstead, William Evershed Wallis, M.B., B.C. Camb., only son of Dr. W. Wallis, Groombridge, to Eileen Mary Constance, only daughter of Sir Walter and Lady Roffey, Thornhill, East Grinstead.

DEATHS.

ALLEN.—On August 28th, at Harley-street, London, W., Richard William Allen, M.D., B.S. Lond.

DAVIES.—On August 30th, after an operation, Hughes Reid Davies, M.R.C.S. Eng., L.R.C.P. Lond., of Gildredge House, The Goffs, Eastbourne, aged 62 years.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PART PLAYED BY THE ENDOCRINE GLANDS IN THE EVOLUTION OF MAN.[1]

BY PROFESSOR L. BOLK,
DIRECTOR OF THE DEPARTMENT OF ANATOMY IN THE UNIVERSITY OF AMSTERDAM AND SECRETARY OF THE ROYAL ACADEMY OF SCIENCES.

THE invitation of the London University to deliver a lecture was accepted by me with great pleasure. By accepting it I intend to express my full approval of the aims of the Anglo-Batavian Society. The English and the Dutch have many psychical and physical characters in common. This resemblance is rooted in the identity of the racial composition of the population of both countries. As I have investigated the anthropology of my people during many years, it would have given me much pleasure to describe this resemblance to you in detail. Attractive as a lecture on this subject would have been, however, this evening I will direct your kind attention to another theme. The desire was almost irresistible to lecture in the country of Darwin, Huxley and Wallace, on the "Evolution of Man." This subject was chosen by me because I believe I shall be able to throw some new light upon this problem of problems.

I intend to describe to you human evolution as the effect of the agency of the endocrine organs. Now, I am aware that this theme is not quite new. The country, one of whose most famous poets—writing at a time when Darwin was still in his boyhood—once said: "And I am born where men are proud to be"—this country in later times also has brought forth biologists of uncommon intellectual power who, by their investigations, have added considerably to our knowledge of the evolution of man. I fear it would be too severe a strain upon the modesty of my colleagues, Prof. Elliot Smith and Prof. A. Keith, if I undertook to sketch their merits with regard to the deepening of our insight into the historical development of man. But in drawing your attention to the most recent publication of Prof. Keith, concerning the relation between evolution and the endocrine system, it will become clear to you that the side from which I approach this problem is not in all respects a new one. The time at my disposal is short, and I am obliged to treat my subject in a very condensed manner. I shall begin with a summary.

Functions of the Endocrine Organs.

It is certainly superfluous to enter into details as to the function of the endocrine organs. It is generally known that the secretions of these organs are in some obscure way correlated with the general condition of the organism. And it may be sufficient to mention that by this secretion the metabolism of the organism is regulated. This function being of a purely physiological nature will not be discussed in the present lecture. A second function of these organs, which undoubtedly stands in close relation to the one just mentioned, is of greater interest to the morphologist. The endocrine organs control the harmonic development of the body, they are the sources of the directing factors of morphogenesis. The different parts of the body do not develop in an autonomic way, independent of each other, but during development they stand in continuous interrelation. The maintaining of this correlation is that function of the endocrine system which I call their architectonic function. By virtue of this function they are the controlling factors of the development of the body; each morphological feature is subject to their influence. Thus it is clear that these organs are of the utmost significance for the ontogenesis of man. The question, however, which will be treated on in the present lecture, concerns their significance for phylogenesis, the historical evolution of the human body. And I intend to demonstrate to you that the endocrine organs have to a very large extent controlled this evolution also.

It may be accepted a priori that some interrelation must exist between phylogenetic development and the function of these organs. For in human individuals of that a far milder form of this disease is very common indeed, and that it is characterised by slight sore-throat and fever and some mild gastro-intestinal symptoms. Many of our nurses at the infirmary suffered from mild sore-throats at the time I spoke of, and sore-throats are not as a rule common amongst them; and if inquiries are made when a definite case of encephalitis occurs, one generally finds that others in the house, especially the children, have, or have had recently, slight colds or sore-throats.

---

[1] A lecture delivered at the Royal Society of Medicine on May 12th, 1921, under a scheme for the exchange of Lecturers in Medicine between England and Holland arranged by the Anglo-Batavian Society in coöperation with the Royal Academy of Sciences in Holland and the University of London.

I cannot pretend to have proved my theory, but I think it is right to put it forward for others to criticise and possibly either to confirm or to confute; and I do so feeling that in some ways a man who practises as I do as a consulting physician in a wide and somewhat thinly populated country district is in a better position for observing what one might term the natural history of diseases than those who practise chiefly in our large towns.

I am, Sir, yours faithfully,
H. WILLOUGHBY GARDNER, M.D., F.R.C.P.
Shrewsbury, Sept. 1st, 1921.

THE SWIMMING-BATH AND EAR INFECTION.

To the Editor of THE LANCET.

SIR,—In addition to the simple Eustachian catarrh described by Dr. K. Amersbach, of Freiburg, in your last issue (p. 519), workers in throat and ear clinics are only too well aware of the occurrence of the much more serious purulent otitis media as a consequence of bathing. So regularly does every warm summer bring cases of ear suppuration due to this cause to our notice that it would scarcely be an exaggeration to describe the incidence as an epidemic to which all bathers may be at some time or another exposed, and it is noteworthy and regrettable that the infection is quite frequently of a highly virulent type, as the serious sequelæ show. I have just had two cases of cerebellar abscess and lateral sinus thrombosis, both of which followed an acute middle-ear infection induced by bathing.

To suggest a method of preventing such accidents is rather difficult. On a hot summer day the refreshment of a cool dip is irresistible, and so people will only smile at the very slight risk of ear infection. Sufferers from chronic otorrhœa, however, should always be warned that bathing for them does entail a very serious risk indeed. On the other hand, a person with an old, dried-up perforation in the membrane is probably not any more prone to middle-ear infection than a normal subject, since it is almost certainly through the Eustachian tube and not through the external meatus that the infection reaches the middle ear in most cases. This raises the question whether the water is itself to blame for the infection, or whether it is not rather due to the washing-up of the patient's own nasal and naso-pharyngeal secretions into the middle ear in the same way as when that cavity is infected by the sniffing up of liquids into the nose for cleansing purposes.

Nevertheless, that pyogenic organisms are present in the water people are habitually bathing in cannot be denied, and every effort should be made to render and to keep such water as clean as possible. This, we must admit, must often be a difficult ideal to realise, but the matter is one for consideration by public health authorities.

Fresh water swimming-baths should be emptied and refilled with clean water not once but several times in the course of the day when there are many bathers, although this naturally necessitates a plentiful supply of water.

This precaution should also be adopted if possible at public sea-bathing establishments. There seems to be a popular notion prevalent that sea-water has the property of keeping itself pure and free from germs. This, of course, is an error. Wyatt Wingrave has often told me that he has always been able to grow the *B. coli communis* from the sea-water on the beach of any of our seaside resorts. And if this is true of water open to the sea, how much more contaminated must water be when it is enclosed in a public bath, where, between one full tide and another, crowds of bathers of all kinds are splashing about, adding each his own quota to the sum total of the bacterial flora.—I am, Sir, yours faithfully,

Wimpole-street, W., Sept. 3rd, 1921. DAN MCKENZIE.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—I wish to disclaim any connexion with the publication of a paragraph in the *Daily Mail* of August 31st, in which my name occurs with reference to a case of Cæsarean section, and at the same time to protest against the exposure of such medical details in the lay press. On this occasion I am informed that a reporter visited the home in question and obtained such details as he required, in order to dish them up for the palate of the newspaper reader.

I am, Sir, yours faithfully,
BECKWITH WHITEHOUSE, M.S., F.R.C.S.,
Honorary Obstetric Surgeon, General
Hospital, Birmingham
Birmingham, Sept. 3rd, 1921.

LATE EFFECTS OF GASSING OR TUBERCULOSIS?

To the Editor of THE LANCET.

SIR,—Dr. J. B. Hawes's experience of the late effects of gas poisoning, the subject of an annotation last week, agrees with my own experience among tuberculous pensioners while tuberculosis officer for Carlisle. Patients suffering from the after-effects of gas poisoning do not show the usual constitutional symptoms associated with tuberculosis, but on the contrary are fairly well nourished. They complain of cough with a copious muco-purulent sputum in which repeated examination fails to reveal the tubercle bacillus. The chest is emphysematous in type, and in marked cases there is evident dyspnœa during rest, and sometimes asthmatical attacks occur at night. The physical signs which may be almost entirely confined to one lung consist of some impairment of the percussion note or definite dullness and faint breath sounds with prolonged expiration, accompanied by fine and coarse râles or rhonchi. The vocal resonance is also diminished. The condition remains practically unchanged under treatment. There is some amelioration during the summer, but the symptoms become aggravated during damp weather.

Such cases are referred by the Ministry of Pensions as tuberculosis, but I am of the opinion that the tubercle bacillus is in no way responsible for the condition which is one of chronic interstitial pneumonia. I am unable to state definitely the proportion of these cases, but I think I came across 5 among 70 pensioners referred to the tuberculosis dispensary.

I am, Sir, yours faithfully,
Eccles, Sept. 5th, 1921. J. E. SPENCE.

EARLY DIAGNOSIS IN DIPHTHERIA.

To the Editor of THE LANCET.

SIR,—In your issue of May 21st Dr. Frederic Thomson emphasised the great practical importance of early diagnosis in diphtheria, and two weeks later Dr. S. R. Collier related the steps taken by the Public Health Committee of Wimbledon to ensure to the practitioner a ready supply of antitoxin. It certainly seems useless for teachers and authorities like Dr. Thomson to instil into students the need for immediate antitoxin treatment on the diagnosis or justifiable suspicion of a case of diphtheria, if we, as practitioners, are to be hindered from carrying out such treatment by laymen on local district councils.

I am practising in a home county town not 35 miles from London, and some time ago I had a pigmentation of the skin. You know that the cause of Addison's disease is an affection of the suprarenal body. And so the following facts may be stated. An affection of an endocrine organ causes a reappearance of the pigment in the skin of white man—that is to say, that an essential human character is lost by this affection, the individual reacquires a quality of one of his ancestors. And so it seems to me to be not a daring conclusion that the loss of pigment during the course of evolution was due to the suppressing influence of the suprarenal body. As soon as this organ is affected its normal function is modified, the check is removed which hinders the formation of pigment in the skin, and it becomes coloured again.

Orthognathy of Man.

I pass on to another human character. Man differs from the other Primates in a typical way by his orthognathous skull. In the nearest relatives of man, the anthropoids, the facial part of the skull is strongly developed, the massive jawbones predominate over the braincase, and the brow ridges overhang the orbits like penthouses. The anthropoids have a small facial angle. In man, on the contrary, the facial part of the skull is of slighter development, the jawbones are scarcely prominent, the brow prominences project but little, and the facial angle is a large one. Now, in judging the human form, I lay stress upon the fact that orthognathy is a fœtal character of all Primates. It is only during the second half of ontogeny that the facial part of the skull begins to project strongly. In man the embryonic condition persists, the development of the jawbones is a very slight one. Therefore the orthognathy of man must also be considered as the consequence of the suppression of a developmental potentiality. This suppression does not act equally strongly in all human races. And again, in the black races in general and the Australian natives in particular, the prominence of the jaws becomes least suppressed. As regards this characteristic also the white race, judged from my standpoint, is the most human.

Is there any indication of the endocrine gland by the agency of which the orthognathy of man may have come about? Certainly. For though the strong development of the jaws, especially in the white races, is suppressed, its developmental potentiality is not annihilated; it has become latent. There are known to all of you cases in which, in some individual, the jaws recommence to grow in an anomalous manner, and the brow prominences begin to project, this being one of the main symptoms of acromegaly, well recognised as a disease of the hypophysis. It seems as if in these cases the hormones of this endocrine gland act insufficiently and the latent potentiality reasserts its power. This occurrence is comparable to that in which the higher psychical functions of man are abolished, and the brutal instincts which are normally inhibited reacquire control of his actions.

The affection of the hypophysis causes yet another phenomenon in accord with the principle of my theory. In comparing the hand and foot of man with those of anthropoids, striking differences, specially of the foot, may be noticed. In anthropoids, as you know, the terminal part of the hind limb is hand-shaped. Again, I want to emphasise the fact that in its outer form the foot of man has retained its fœtal feature; the hand-like foot of the anthropoids is the differentiated form. So also in the outer form of man's foot an embryonic condition persists. But it is not only to this point that I wish to draw your attention. The anthropoid hands are clumsy and heavy, those of man slender and modelled after a more elegant pattern. And if I had sufficient time to do so I could prove to you that also the hand of man is of a more fœtal form than that of apes. Now I remind you of the fact that another acromegalic symptom is the enlargement and increasing clumsiness of hands and feet in man. It seems, therefore, that like his jaws the terminal parts of his limbs are freed from a suppressive influence in man; his pituitary body is affected, and a lost ape-like condition returns.

Closing of the Cranial Sutures.

The next essential characteristic of man which I shall discuss is of a more histological nature. As a rule the sutures of the skull close very early in apes, and there is a great tendency for them to unite in childhood. Some years ago I published a thorough investigation of this phenomenon, and demonstrated that, for instance in gorilla and orang, the sutures in the vault of the skull, as a rule, have disappeared before the spheno-occipital synchondrosis is closed. In man, on the contrary, the synostosis of the cranial bones is postponed to a very much later period than in anthropoids and the disappearance of the sutures seems to be more a symptom of senescence.

The sutures of the skull are the lines along which the enlargement of the cranial bones takes place, and this enlargement is requisite as long as the brain-case increases in size. The function of the sutures is terminated, therefore, as soon as the brain has attained its adult proportions, after which they can close without harm. This happens in all other Primates. The persistence of the sutures in man long after the brain is full-grown is again to be considered as the continuation of a fœtal condition; and like the other characteristics already mentioned, the persistence of the sutures also results from a retardation or suppression of a growth process—namely, the ossification of the fibrous tissue between adjacent bones. This retardation in the closure of sutures exhibits itself in yet another way—namely, the occasional permanence of the interfrontal suture. As a rule this suture is closed in man in early childhood, as it does also in anthropoids, whilst in lower Primates the frontal bones have become fused together even before birth. In a certain percentage of men, the interfrontal suture does not close—a phenomenon which is distinguished as "metopism." In an investigation published some time ago, I demonstrated that metopism is not at all due to increased intracranial pressure, caused by exceptional enlargement of the brain, as is asserted by some authors. Metopism is nothing but the result of the same process by which the sutures in man generally tend to persist.

Metopism is certainly one of the last acquired somatic human characters, and it is very remarkable also that this character is found more frequently in white men than in black races, and, further, that among the former it occurs most frequently in the Norvic race. In the latter it is found on an average of 8 or 9 per cent. Thus the race which is distinguished by the absence of pigment, by the high degree of prognathism, and also with regard to metopism, is found in the highest level of human evolution. Is there any indication as to the endocrine organ by the agency of which the ossification of the sutures in the skull was retarded? Certainly. And this indication is afforded again by pathological observations. It is more than a probability that this organ was the thymus, for the osteogenetic processes are regulated by this gland. This is not a mere supposition, for we know that extirpation of this organ in young individuals or destruction of the same by some affection causes a disorder in the normal osteogenesis. This disorder is recognised by the rachitic changes in the tissue of the bones. Now it is a matter of fact that one of the symptoms of a rachitic constitution is the premature and irregular closure of the sutures of the skull. Therefore we conclude that, since normal function of the thymus prevents premature closure of the sutures, the regular ossification of the sutures, and the time at which this process takes place depends on the agency of this gland.

Labia Majora and Hymen in the Human Female.

I will now proceed to discuss another essential somatic characteristic of man which also is a perpetuated fœtal feature, but of a nature quite different from the foregoing. Females of the human species differ from those of the other Primates by the possession of labia majora and of a hymen. I shall not discuss this latter formation, its ontogenesis being as yet a subject of much controversy. I lay special stress upon this difference between man and apes, because it is an anatomical characteristic, for which it cannot be claimed that its development was of any value to the individual in the struggle for life, or may have been acquired by the influence of some external factor. Many years ago this difference between man and apes was the subject of an attack made by Bischoff, the Munich anatomist, on the Darwinian doctrine. He maintained that the complete absence of labia majora proved conclusively that there was no relationship between man and the apes. Now Bischoff overrated the value of this argument, because he committed the mistake of examining only adult specimens. If he had extended his researches to fœtal material he would have destroyed the foundation of his argument against Darwinism. For—and this is an essential point for the present discussion—in the embryo and fœtus of other Primates there are also during a shorter or longer period a mons veneris and labia majora. As you know, the labia majora, together with the mons veneris, are differentiated from the outer genital folds. Now these folds appear in apes as in man. But whilst in apes as a rule they are flattened and disappear completely, in man, on the contrary, they increase; their ventral part surrounds and covers the genital papilla, or clitoris, so that this organ comes to lie deeper, whilst in apes it remains at the surface. The lateral parts of the external genital folds increase also, and form the labia. So the special structure of the external genitals in women is a persistent fœtal character.

Now it is very interesting that in anthropoids the tendency to this perpetuation is present. For in anthropoids the flattening of the outer genital fold is not as complete as in lower Primates. So in his monograph on the chimpanzee, Sperino remarks that on both sides of the entrance of the vestibule there is a slight prominence, caused by a thickening of subcutaneous fat; and there is also an indication of a mons veneris. Quite the same condition is noted by Deniker in

PORTLAND convict prison has been converted into a Borstal Institution making the fifth institution of the kind in England

THE late Sir George Henry Savage left his books on insanity to the Bethlem Hospital and his collection of minerals to the Natural History Museum, South Kensington

THE George Henry Lewes studentship in physiology, value £215 a year and tenable for one to three years will shortly be vacant Application to Prof Langley at the Physiology School Cambridge

WIGAN INFIRMARY—*During the 13 weeks of the coal strike the Wigan Infirmary lost more than £3000 by* the lapsing of the weekly subscriptions which the miners voluntarily contribute to the maintenance fund of the hospital A special effort week is being organised in the town with the object of wiping out the temporary loss of *subscriptions*

PRESENTATION TO A MEDICAL MAN—On the occasion of his resignation from the position of surgeon in charge of the Glasgow Orthopædic Institute Dr William Laird has received a presentation of silver plate As many as 14 000 cases of disabled soldiers have passed through Dr Laird s hands since the opening of the Institute He proposes to devote himself to private practice

THE Manchester Corporation have made grants amounting to £6000 to local hospitals including £1500 to the *Royal Infirmary and £1200 to Ancoats Hospital* The corporation have received Government grants for tuberculosis treatment £17,500, for maternity and child welfare work £13,500 and for treatment of venereal diseases £4161, in respect of estimated expenditure for the half *year ending Sept 30th*

DRUGS NEEDED IN RUSSIA—*A cablegram received* from the Russian Committee of the Friends Relief Committee (27, Chancery lane London W C 2) states that there is urgent need in the famine area for the following drugs—namely, atropine sulphate caffeine iodine, ipecacuanha root, *neosalvarsan potassium iodide and pilocarpine* hydrochloride These drugs can be put to good use if placed at the disposal of the Committee

VISIT OF SWISS MEDICAL STUDENTS TO VIENNA—On Oct 7th about 100 medical students accompanied by the professors from a number of Swiss clinics will pay a visit of inspection to *hospitals* and clinics in Vienna Special courses lasting a fortnight are being arranged The visit was proposed by Prof von Eiselsberg (surgery) of Vienna to his old assistant Dr P Clairmont now professor of clinical surgery at Zurich on a visit paid by the former to Switzer*land in July*

WINSLEY SANATORIUM—*On August 31st a large* number of representatives of Bristol and Bath Corporations and of the Wiltshire County Council visited the sanatorium at the invitation of the executive committee of the institution During an informal gathering which followed inspection of the grounds, various speakers expressed their sense of the excellent work now being carried on there and paid tribute to the pioneer efforts of Dr Lionel Weatherly whose labours were largely instrumental in the foundation of the sanatorium in 1903 and who became the first chairman of the managing committee when the buildings were opened in the following year

Relation of Endocrine Glands to General Retardation.

Finally, I will return to the principal problem of the present lecture and put the question: whether this general retardation, too, is in any way related to the agency of the endocrine system? That the rate of development generally is regulated by this system is sufficiently demonstrated by experimental researches of late years. Though these experiments are yet in an initial stage, we have already become acquainted with an endocrine organ, able to *accelerate* the development. This organ is the thyroid gland. I mention only the statement that feeding tadpoles with thyroid accelerates the metamorphosis of these animals. But, as far as I am aware, experimental investigations have not yet brought to light any element of the endocrine system able to retard the rate of development. I am convinced, however, that there must be such an inhibitory element in the human organism. And I have a strong belief that this is the pineal gland. This belief is based on the occurrence of well-known anomalous conditions. Every physician is acquainted with the very deplorable cases of so-called premature sexual development. This anomaly occurs in boys as well as in girls, but apparently more frequently in the latter. Several instances of this pathological condition, in which, for example, young girls of six or seven years become pregnant, are dealt with in literature. Now I believe these cases must be explained in this way, that in such individuals the arresting influence of the endocrine system on the function of the genital glands was insufficient, and the check which hindered the maturation of germ cells was removed too early. Considered from this point of view the premature sexual development appears as a physiological atavism. Observations of late years have shown conclusively what endocrine organ is responsible for this anomaly. You know it is the pineal gland. These observations justify my assertion that this organ is, and has been, the regulator of maturation and that it was principally by its agency that the general vital process of man was retarded.

Adaptation to Animal Food.

And now, in conclusion, only a single remark concerning the primary cause of this retardation. I consider this to be the adaptation of the human species to animal food. All other Primates are herbivorous or frugivorous, only man has accustomed himself to an omnivorous existence. This must thoroughly have changed his metabolism. The whole endocrine system functions as a unit. All its organs are physiologically associated with each other, and the effect of this association is an equilibrium. Now in each organism this equilibrium is in harmony with the chemical structure of the food, of the material which must be assimilated. If this material is exclusively or principally vegetable, the endocrine system must function in a somewhat different manner than when the material submitted to its regulating power is of animal origin. Therefore, by a transition from a vegetable to an omnivorous diet, the regulation of the metabolic processes must necessarily be modified. Is there any indication as to the nature of this modification? I think there is. I draw your attention to the very interesting fact that as a rule the development of carnivorous animals, mammals as well as birds, takes place at a slower rate than that of herbivorous ones. I consider this fact as an argument in favour of my assertion that the retardation of human development is in some way or other connected with the adaptation of man to animal food. I have not the slightest idea of the relation of cause and effect in this case; the question is more physio-chemical than morphological.

Conclusion.

I must finish. However much I may regret to be obliged to condense the treatment of my subject, I must come to a conclusion; and let me end with a general remark upon the endocrine system. There exists, as I have mentioned already, a close relation between all internal secreting glands; the whole endocrine system is an organic unit, it is a sort of controlling super-organisation in our somatic organism, an *imperium in imperio*. And this "imperium" fulfils its task in a stimulating or a suppressing manner. The endocrine glands are, so to say, the sense-organs of the autonomic system, sensitive only to chemical stimuli, as the sense-organs of the cerebro-medullar system to physical stimuli. These organs judge the quality and intensity of the chemical substances produced in the body, and regulate the nature and the quantity of the same by means of their hormones. And certainly it is not a mere chance that the principal organs of this system are derived from the epithelium of the foremost part of the alimentary tube. I believe that originally they controlled also the chemical nature of the food, before there were senses of smell and taste. By investigations and observations on the endocrine system during late years we have arrived at a very important point. It seems to me that we have reached a summit, and a large plain and wide perspectives lie open before us.

MEDICAL CONGRESS AT YVERDON.

A MEDICAL congress is being arranged for Oct. 8th and 9th to be held at Yverdon-les-Bains, which lies at the S.W. end of the Lake of Neuchâtel, 40 minutes by rail from Lausanne. The springs are of two kinds. One gives a supply of 12,000 litres an hour of a sulphur water, at a temperature of 24° C., analogous to that of Aix-les-Bains, Eaux Bonnes, or Cauterets. The other is a cold water containing $MgSO_4$. Both are used for inhalation as well as bathing, and among the special indications are mentioned arthritism, gout, obesity, diabetes, high arterial tension, plethora, and auto-intoxication. The season lasts from May until October.

AN EXAGGERATED REPORT.

UNDER this heading there appeared in our issue of June 11th, p. 1280, a démenti from our Geneva correspondent of the report current in the lay press that a certain surgeon had extracted a beating heart from a still living body. The accusations brought against this surgeon, who is none other than Prof. E. Kummer, by some of his junior colleagues at the university clinic, have formed the subject of a judicial inquiry nominated by the Conseil d'État. As regards the particular accusation referred to above, the court of inquiry find that the evidence refutes the "singularly hasty" reproach of homicide ("assassinat involontaire") which had been made. Prof. Kummer has emerged from the whole inquiry, whose scope was considerably greater than the clearing up of this one incident, with his reputation enhanced.

THE OLD "IMPREGNABLE."

THE old wooden battleship *Impregnable* has for so long figured as the least healthy of the boys' training ships that few will regret to see that she is to be broken up. She had 78 cases of pneumonia in 1913, 42 in 1914, 197 cases of mumps in 1913, 149 of measles in 1914, in each case the largest number shown by any ship in the training service. That they were not all attributable to this individual ship, but also to the sister ships associated with her, is doubtless true; still all old wooden ships are badly ventilated and likely to be overcrowded, and are consequently unsuitable for barracks. That another of them has gone from the Navy and may be replaced by a more modern ship gives hope for better health returns from the training establishment, in which *Impregnable* had a pneumonia incidence in 1913 ten times, and in 1914 five times as great as that of the general service.

ANOTHER CONSUMPTION CURE IN THE LAY PRESS.

WE have received a 12-page pamphlet containing extracts from several Queensland newspapers regarding a new specific treatment for tuberculosis stated by its inventor, Dr. De Luca, to be similar in principle to the Spahlinger cure. The exact nature of the remedy is not revealed, but it appears to be a tuberculo-protein administered as a vaccine, first by mouth and then subcutaneously. No clinical or pathological data have yet been given. Dr. De Luca is given in the Australian Medical Directory for 1914 as an M.D. of Naples, qualified in 1895, but he does not appear to have taken any registrable qualification in the country where he is now practising, or, at any rate, to have taken any steps for its registration. Nor has he communicated anything concerning his remedy to a medical society or a medical journal.

A NEW PROCEDURE IN OBSTETRICS.

UNDER the above title Dr. Lorenzo Diaz, of Toluca, Mexico,[1] describes how he treated a transverse presentation ("acromio-iliac right dorso-posterior") with prolapsed arm, in which the membranes had ruptured and all the amniotic fluid escaped before the patient was admitted to hospital. In the face of this difficulty Dr. Diaz took a large Nélaton catheter and inserted it behind the back of the fœtus (which was dead), and using the prolapsed arm to occlude the cervix he injected sterile water through the catheter from a 25 c.cm. glass syringe—sterile water was used because normal salt solution was not available. The result was in any case most happy; version was performed and the child safely delivered. The patient's temperature had fallen to normal two days after the operation, and she made an uneventful recovery.

THE name of the preparation "Chlorosan," made by the Institut Séro-Thérapique et Vaccinal of Berne, has been changed to "Phyllosan."

AN aged medical man's widow, nearly blind, is in want of a bath-chair. "A," 12, Park-lane, Tottenham.

---

[1] Gaceta Medica Balear, July, 1921, vii., 9.

to-day the effect of their function is the development of a human body as it actually exists. But in earlier times, *in the ancestor of man*, there was built up under their influence a form different from the present, a form with more primitive, ape-like characters. So it follows that, if *the endocrine organs control* the development of the body, they must modify their function in accordance with the modifications in the structure or features of this body during the course of time. This fact gives rise to the following question of fundamental importance: What is the nature of the correlation between the morphological *modifications of the organism and the changes in the function* of the endocrine glands? There are two possibilities: either the endocrine organs have adopted their function to the modifications of the body, or the latter are the *consequence of a primary* alteration in the function of the glands. To determine which of these possibilities is the true one is of the utmost importance, for this decision determines our standpoint as to the more fundamental question whether evolution is the result of external factors only, or of those in conjunction with internal ones. This problem forms the general biological foundation of my lecture.

Results of their Suppressive Agency.

The somatic differences between a primitive form and its more differentiated descendant are of a regressive or of a progressive nature. In the first case some anatomical character of the ancestor is *absent* or *not so strongly* developed in the descendant—in other words, the potentiality for development of this character is suppressed or weakened in the course of phylogenesis, and the agency of the endocrine system *in this case was a suppressive one*. In the second case an anatomical character is more strongly developed in the descendant; the agency of the endocrine glands has, in this case, been a stimulating one. Now I intend to *make clear* to you that nearly all essential human characters are the result of a suppressive agency of the endocrine organs. How, you will ask, have you arrived at this conclusion? By two ways: that of embryology and that of pathology. Embryological and pathological phenomena, in combination with each other, throw a very *interesting* light upon the important influence which the endocrine organs have exercised on the evolution of the human body, as I will demonstrate to you. I believe it will be of great use to summarise beforehand the *essentials of my* lecture. I shall give this summary in the form of the following six conclusions:—

1. The essential characters of the human body are a *survival of fœtal conditions.* 2. This persistence of fœtal conditions is the result of a retardation or a suppression of the development of certain general characters of Primates. 3. This retardation or suppression is caused by the agency *of the endocrine organs.* 4. In morbid affections of the endocrine organs this suppressing agency is removed, *and the human body once more acquires* features of some ape-like ancestor. 5. The retardation of development concerns not only purely somatic features, but human development as a whole. The developmental rate of man is *retarded*, the succeeding phases of his life are protracted. 6. This retardation of the developmental rate of man is, perhaps, *caused by the change of the nature of his food*, the frugivorous ancestor of man becoming omnivorous *or carnivorous.*

Hairlessness of the Human Body.

These conclusions, which are so many chapters of a theory of the evolution of man, are *not speculative*, but are founded, as you will see, upon well-known *embryological* facts and pathological observations, with exception of the last of the series, which is merely a suggestion or presumption. The fourth *conclusion implies that diseases of the endocrine* organs influence in the first place the essential human characters. Now, the number of these is very small, and I shall begin by discussing one of the *simplest—namely*, the *hairlessness of the* human body. Many opinions as to the cause of the nakedness of the human skin have been advanced in literature *already*: *natural selection*, sexual selection, climatological influences, and so on. I refrain from criticising these ideas, but draw attention to the fact that nakedness of *the skin is a common fœtal character.* In the embryos of all Primates the hair appears rather late, the development of the hairy covering in this order of vertebrates seems *to be generally retarded.* This retardation is the initial phase *of the process* which resulted in the complete loss of the hairy covering in man, with the exception of the scalp. It is *maintained that* the presence of hair here is due to sexual selection. This assertion cannot be true, *as* I will demonstrate to you. In the skin of a nearly full-grown fœtus *of a chimpanzee* the *pigmentation is* yet wanting, a remarkable fact to which I shall return. But most remarkable is the hairlessness of nearly the whole body; *only* the *scalp bears long* brownish hair. This valuable specimen proves that *the mode* of distribution of hair on the surface of the human body is found already in principle in the anthropoids, and that therefore the agency which caused the nakedness of the human body is already active in anthropoids. Could you wish for more conclusive proof that this nakedness cannot be the result of natural or sexual selection, but is acquired by the influence of an internal factor, which suppressed almost completely *the development of the hairy covering of the* body and perpetuated a fœtal condition?

Now the question arises, what endocrine organ suppressed the development of the hairy covering of the human body? Some very suggestive pathological observations serve as a valuable clue. It is a well-known fact that affections of the pituitary body can influence the state of hairiness in a high degree. This influence does not always bear the same character, but, for the point under discussion, it suffices to recall to mind that it is demonstrated in some patients by the development of a dense hairiness specially all over the limbs and trunk. I am inclined to believe that in those persons the suppressive influence exercised by the hormones of the pituitary body is eliminated, so that the latent potentiality for hair-forming becomes active again.

White Skin of Some Human Races.

We shall now consider a second essential human character—*namely, the white skin of man. Though this be only* a racial character I will discuss it now, because it affords me the opportunity of demonstrating the significance *of the endocrine organs with regard to racial differences.* For it is obvious that if these organs have influenced the evolution of man as a species, the same holds true also, *in no mean degree, as to the differentiation of this species into its races.* The skin of all Primates is coloured by black or brown pigment, and in man some races agree *in this respect with the apes, but a considerable part of* man has a white or somewhat yellowish coloured skin. Many opinions have been advanced as to the means by *which man got his uncoloured skin. None of these will* be advocated here, because I shall throw light upon this phenomenon from my own standpoint.

It need scarcely be observed that of all Primates the fœtus passes a stage during which its skin, *as well as its* iris are free of all pigment. White skin and blue iris are, *therefore, properties of the primate-embryo in general.* But before birth the skin and iris of the ape-fœtus become coloured. *In man in some races these fœtal qualities—pale skin and blue eyes—have become perpetuated*—that is to say, the potentiality to form pigment in the deeper layer of the skin is suppressed. In other races, on the *contrary, this potentiality is preserved; skin and iris become* intensely coloured. But, as will not be unknown to you, this pigmentation of the skin happens after birth; the *negro-babe is born with a somewhat greyish or yellowish* coloured skin. It seems as if the internal factor, which suppresses the formation of pigment in *the skin of white races, exercises its influence already* in the black *races*, where the process of colouring is retarded.

Allow me in this connexion to draw your attention *to a parallelism between two facts?* The developmental factor causing the nakedness of man was already active in anthropoids, as shown in the fœtal chimpanzee with *naked trunk, limbs, and face*, and head covered with *long hair*, quite like a human baby. This is the first fact. And as to the pigmentation of the skin we have seen that the *developmental* factor, by the agency of which a part of the human species became pale-skinned, is active already in the other part; the negro-babe is white-skinned. This *is the second fact.* My conclusion *from these relations* is quite simple. By the preservation of his naked skin man occupies a higher level in the developmental scale *than the other Primates*; so by the permanence of the unpigmented skin *the white race* occupies a higher level than the black races. The race with white skin and blue eyes—the Nordic race—is a more progressive form of man than the black-skinned races. It is, so to say, the most fœtal *of human varieties.* Can it be possible that this assertion affords a key to the solution of the problem why also in other respects the negro is inferior to the white? As you see, my point of view perhaps opens some new perspective for the understanding of the inequality of human races.

After this digression we return *to the matter* in question. We have demonstrated that the paleness of the skin of the white races is due to the suppression of a developmental potentiality present in all Primates—namely, the formation of pigment.

And again we put the question: Which of the endocrine organs must be considered as the starting-point of this phenomenon? This question calls up in my mind the *name* of one of your countryman, Addison. It is superfluous to summarise the symptoms of the *disease named* after this renowned physician. Passing over the general constitutional symptoms, consider for a moment the most characteristic phenomenon of this disease—the

RESPIRATORY EFFICIENCY CONDITIONED BY HYGIENE AND SANITATION.

These figures show that the causes of physical inefficiency are to a large extent preventable. I do not wish to enter largely into details of sanitation and hygiene—as, for example, to point out the effects of insufficient or ill-chosen diets, overcrowding, back-to-back houses, and ill-ventilated workshops—but I cannot refrain from pointing out that, apart from the very important question of diet, these evils lead to a condition of respiratory and circulatory inefficiency largely involving the well-being of the individual. From this statement it will be seen that I attach great importance to the respiratory efficiency of the individual in the acquisition and preservation of physical efficiency. In particular is this the case in regard to bodily endurance. I have been led to this view by my work in connexion with the Royal Air Force. It has been my privilege to study the causes which lead to flying fatigue, and also to endeavour to study the bodily qualifications which must be sought for in the successful airman. To do this satisfactorily it was necessary in the first place to examine successful flying officers, as well as those suffering from various degrees of breakdown. As the results of investigations, with which I shall deal later, it became apparent that for efficiency in air work and for the prevention of physical endurance of the stress of flying respiratory efficiency was of particular importance. As the result of the examination of many hundred candidates for the Royal Air Force it has also become obvious that the same condition applies to all physical efficiency and bodily endurance, whether it be for air work or for work on the ground.

PRESENT KNOWLEDGE CONCERNING RESPIRATORY FUNCTION.

Before dealing in detail, however, with the results obtained in connexion with this work it is necessary to review the present state of our knowledge regarding the processes of respiration, since I believe that a considerable amount of the respiratory inefficiency of the present day may be attributed to the fact that the true significance of the mechanism of respiration is not correctly appreciated, and therefore that the fundamental physiological principles of respiration are not correctly taught and applied.

Broadly speaking, movements concerned in respiration are designed to serve three functions: (1) to provide the body with oxygen and to rid it of carbon dioxide; (2) to act as accessory pumps to the circulation, thereby aiding, particularly in the upright posture, the return of blood to the heart; (3) to massage the alimentary tract, thereby helping to preserve the muscle tone of stomach and intestines.

With regard to the movements of respiration, it is not proposed here to enter into the time-worn controversy as to the exact action of the various muscles engaged in the respiratory processes, nor as to exact movements performed by individual ribs. Too much time has already been wasted by hypothecating such actions and movements from minute considerations of the dead structures. There is a great difference between the living and the dead thorax. It is better for ordinary purposes to consider the movements of the thorax as a whole. Although the muscles concerned in respiration are so arranged that they can be coördinated in various ways to bring about the processes of inspiration and expiration, there is, undoubtedly, a most efficient way for each process, and for bodily efficiency and endurance it is important that this way be employed. The essential movements of quiet inspiration are the descent of the diaphragm and the raising of the lower ribs. When inspiration is deeper the movement spreads progressively in undulatory fashion from the lower to the upper ribs, so that the upper part of the chest is seen to rise. This upper chest movement is to be regarded as the accessory part of inspiration. On this account it becomes particularly prominent when breathing is greatly increased in depth by excessive exercise, or becomes laboured in disease, or when correct inspiration is impeded by occupation or clothing.

CLOTHING AND RESPIRATION OF WOMEN.

It may be argued that costal breathing is the normal type of breathing for women. This should not be the case when the clothing is properly adjusted. This does not mean that costal breathing is altogether due to wrong clothing. It is probable that women normally employ the costal element to a larger extent than men—since, as suggested by John Hutchinson, it forms the accessory mechanism for efficient quiet respiration during pregnancy. That such breathing, however, is in large part due to clothing is shown by the fact that in cases of complete hypospadias which have been wrongly regarded as females and clothed as such, the type of breathing has been observed to be what may be termed female in character, although the subjects were in reality males. It would be a mistake to teach that costal breathing alone is normal for the female. Young girls and women should be taught that correct inspiration is always associated with good diaphragmatic action, and that the upper costal element, however large it tends to be, should be regarded as the accessory element. The clothing of women, therefore, should be adapted to give free abdominal movement. I have not had sufficient opportunity to study widely what may be termed normal female breathing, but at a school of physical training I noticed that abdominal breathing was present.† As regards the male, however, it must be emphatically asserted that the time has come to abandon the idea that by striving after a large upper chest expansion the respiratory capacity is greatly increased. In this type of breathing the pit of the stomach is usually observed to move inwards instead of outwards during the inspiratory process, while expiration is accompanied by an outward movement in this region. Many observers have already noticed that this type of respiration is less efficient. In reality the vital capacity in such type of breathing is considerably less.

MEASUREMENT OF UPPER AND LOWER CHEST EXPANSION.

Radiographic evidence has also shown that in such breathing the diaphragm moves little if at all; indeed, in extreme cases the abdominal contents pass farther up into the thorax, so that in reality the apparently increased lung capacity consists of the pushing of the abdominal contents higher into the thorax. Although prevalent at one time in the army, this type of breathing has now been abandoned; possibly it attained a vogue owing to the frequency with which phthisis is found to attack the apex of the lung. As shown later, however, upper costal breathing is adequate only for the expansion of the anterior part of the upper lobes; the efficient expansion of the apex of the lung is largely dependent upon efficient diaphragmatic and lower costal breathing. As a guide to respiratory efficiency the measurement of upper chest expansion should be abolished or at least combined with a measurement of the increased size of the chest at the level of the lower ribs. This latter is the more important measurement. On deep inspiration there should be a movement out of the pit of the stomach, together with considerable expansion of the lower part of the chest. Correct inspiration, therefore, consists of the contraction of the diaphragm, attended generally by an upward movement of the lower ribs, full inspiration being attained by a wave-like movement which passes to the upper ribs. Observation shows that it is the type prevalent in individuals who possess the greatest bodily endurance. By its means the greatest respiratory capacity is attained, and by its means alone is the lung adequately expanded in all its parts.

---

† Dr. Mina Dobbie, medical officer to the South-Western Polytechnic School of Physical Training, tells me that she attaches considerable importance to the increase of the abdominal measurement during inspiration over that during expiration as a sign of progress in efficiency. Her records certainly bear out this contention.

the gorilla. He writes verbatim as follows: "In accordance with my description the labia majora exist in the fœtus of the gorilla and the nymphæ are very like those of the human fœtus. These facts are in contradiction with the assertion of Bischoff." The same holds good for the orang, for this ape also possesses rudimentary labia majora. Thus we see that the disappearance of the outer genital fold is already incomplete in anthropoids. It seems as if the course of morphological evolution which resulted in the human form of external genital organs made its first progress in anthropoids, for the retarded flattening of this fold in apes may be regarded as a transitory stage to the persistence of the same in man. Now in man the individual variability of the labia majora is considerable. I do not know if this variability forms a difference between black and white races. The collection of the anatomical museum of the Amsterdam University contains only two examples of external genital organs of female negroes. Both are characterised by large labia minora and very scanty development of the labia majora. This is in accordance with what I expected to find, but if my observation be an exception or the rule, I cannot say.

Is it possible to ascertain what endocrine organ has effected the perpetuation of this fœtal condition in man? I think so. In some instances one observes an ape-like condition—that is, a very scanty development of the outer genital organs—in individuals of the white race. These pathological conditions again furnish a hint as to the endocrine organ by which the growth of the labia majora is regulated. This gland is the thyroid. I shall confine myself to enumerate only two facts in favour of this view. The first fact is that after extirpation of the thyroid the labia majora commence to atrophy, and the second, that atrophic or infantile female outer genitals begin to develop more strongly after injection of thyroidine. These facts justify my assertion that the development of the labia majora and mons veneris as an essential human character was due to the agency of the thyroid gland.

Position of the Occipital Foramen

Now there still remains a group of essential human characters of which it is easy to demonstrate that they are persisting fœtal conditions. For the sake of conciseness, however, I must confine myself to a simple enumeration and some brief remarks on these features, because I prefer to give you a somewhat complete survey of my theory of human evolution, and such a survey requires also an explanation of the fifth and sixth conclusion previously mentioned. One of the most characteristic features of the human skull is the central position of the occipital foramen. It is a rather common opinion that during the evolution of man this foramen is shifted forward, because in apes it occupies a more backward position. As the result of an extensive investigation I have come to a different conclusion. In the fœtus of all Primates the occipital foramen occupies during a shorter or longer phase a central position, as in man. In man this primitive position is fixed, whilst in the other Primates the foramen shifts backward. Therefore there is no question of a shifting forward in man, but the shifting backward, normally occurring in Primates, is inhibited in man. It is, however, very interesting that this displacement occurs also in man to a small extent between the seventh and twelfth year. Thus also the structure of the base of the human cranium appears as a persistent fœtal condition, like its prognathism and the high vaulting of its roof. As a further special human character I mention the shape of the pelvis, which is very primitive. In vain you will try to find in the human fœtus a transitory stage of this part of the skeleton similar in form to the pelvis of lower Primates. The broad short iliac bone is characteristic of an early stage of development. In man this stage is fixed; in anthropoids the beginning of this process is seen; in lower Primates it is transformed into the long, narrow bone common to many mammals.

Structure of Aortic Arch and Kidneys. Weight of the Brain

I will give further instances. The arrangement of the branches of the human aortic arch differs from that of apes. Now the manner of branching in man represents an earlier embryonic stage than that in apes. And to put it briefly, the same may be remarked with regard to the difference in the structure of the kidneys. Man possesses kidneys with a greater number of papillæ, a primitive condition; the other Primates, with exception of the American monkey Ateles, have kidneys with a single papilla. I regret that want of time prevents me from a discussion on these points, and also from a debate on the principal difference between man and apes—namely, the considerable weight of his brain. With a very conceivable scepticism you might ask me if this characteristic is also the result of an inhibition in the morphogenesis of man? It may sound paradoxical, but I answer this question in the affirmative. The considerable weight of the human brain is the result of the fixation of an early developmental relation between this organ and the body as a whole. In apes this relation is fixed in a more advanced stage of development, in which the weight of the brain has already become relatively smaller. The earlier the relation between brain and body is fixed, the larger the volume of this organ becomes. Viewed from this standpoint the considerable weight of the human brain appears to us as dependent on the function of the endocrine system. In the masculine sex the relation is fixed somewhat earlier than in the female; in the microcephalic idiot the relation is fixed too late. I restrict myself in giving you only the main line of my opinion as to the origin of the large volume of the human brain. The treatment of this subject would require a special lecture, and is surely worthy of one.

Retardation of Germinal Development in Man

In the foregoing I have given the principal arguments in favour of my assertion that each somatic characteristic of man is the result of a retardation or an arrest of a definite part of the developmental process. So the human body in its actual state gradually evolved by the successive loss of somatic features of the pithecoid ancestor. I cannot mention a single essential human character which is a new acquirement—an addition. Only the high differentiation of the facial and laryngeal muscles in man may be considered as such a really progressive feature; but this progression was a consequence brought about by his psychical evolution. Now I am convinced that this arrest or suppression of the development of somatic characters is the expression of a more general process—namely, the retardation of the vital process of man as a whole. The rate of development in man is retarded with the consequence that the infantile and puerile phases of his life are prolonged; the duration of man's life is extended. This general retardation concerns the somatic as well as the germinal part of his organism. For the sake of conciseness I restrict myself again to some remarks regarding the retardation of his germinal development. The generative glands of women have the very curious peculiarity that there is an interval of 10 to 15 years between the completion of the histological differentiation and the commencement of the physiological function of the organ. As far as I am aware this phenomenon is met with only in the genus Homo. The possibility, however, that there are other mammals—specially among those of larger dimensions—in which the same takes place is not to be denied. But it certainly is not a rule. As a rule the genital glands in mammals behave like other organs; function begins as soon as the histological differentiation is completed. The condition as found in man is not a primitive one. At the end of the second year the human ovary contains its final number of germ cells. There is no further increase. There follows a rather long period during which the ovary remains in a state of latency, as if it were dead though living. This condition lasts till the development of the somatic part of the organism has progressed far enough to undergo the consequences of the function of the germinal part—that is, conception and pregnancy. This period of latency of the genital glands, this prolonged state of childhood in man, must have been intercalated during man's evolution and can only be explained by an arrest of the vital process, by a retardation of his development.

And this very particular biological phenomenon, this alteration of the utmost importance in the vital process of mankind, has perhaps been the mightiest cause of the evolution of man as a social being. For by this retarded development the awakening to consciousness of man is delayed till long after birth, the time of life in which the human individual is able to support himself, when he can begin his struggle for life, is delayed till a rather remote epoch. During this protracted childhood he remains dependent on his parents, forming with them a biological community, a family in its most primitive form. And the family is the element of society.

Inequality of the Sexes

But not only the evolution of man as a social being is rooted in this arrest of his development, but in my opinion the undeniable inequality of the two sexes (with the superiority of the masculine) has taken its starting point from this arrest. If retardation of the developmental processes be the fundament of human evolution, then that sex has attained the highest level of human evolution in which this retardation is most pronounced. And without doubt this is the case with the masculine sex. A very interesting subject for a special lecture! He who proclaims the inequality of the human races must proclaim the same for the sexes. Yet there is a striking difference. The superiority of the white race above the negro is caused by the greater *extensity* of the process of retardation, the superiority of the masculine sex is caused by a greater *intensity* of the same.

circumference to the inner wall of the thorax by the negative intrathoracic pressure. Thus, when its two parts contract it acts like a true piston, moving in a forward and downward direction. The lungs, including their roots, follow this movement, which therefore tends to bring about expansion throughout the whole lung, including the apex, which would otherwise be ill-expanded. In quiet, normal breathing the amount of movement of the right dome is about half an inch, that of the left dome and of the central tendon somewhat less.

MOVEMENTS OF THE RIBS.

In general, two movements of the ribs have been recognised as taking place in inspiration—namely, (1) round an axis corresponding to the spinal articulation, increasing the back-to-front diameter of the thorax; (2) round an axis corresponding to the spino-sternal articulation, increasing the diameter from side to side. Owing to the variation in size, shape, inclination, and articulation of the ribs, such an explanation, while essentially true in a general sense, is imperfect. It is better, as Keith does, to divide the ribs into two sets: (1) the upper, the second rib to the fifth; (2) the lower, the sixth rib to the tenth. These two sets differ in their musculature, in the nature of their articulation and ligaments, in their shape and arrangement, and in their movements. The first rib is not looked upon as one of the costal series; together with the manubrium sterni it forms an operculum to the chest and performs a special movement of its own. The lowest two ribs, inasmuch as they are unattached in front, are essentially a part of the abdominal wall. It is on the movement of the upper ribs (second to fifth) that most of the observations upon rib movements and the action of the intercostal muscles have been made. The following view has been put forward by Keith as to the mode of action of the intercostal muscles. The purpose of the upper rib movement is the expansion of the upper lobe of the lung, particularly in its anterior part. When concerned in inspiration both sets of intercostal muscles act together, and draw up the upper ribs towards the operculum, which acts as a fulcrum. During the succeeding expiration the lower set of ribs are fixed and act as a fulcrum, the upper set being drawn down towards them by the intercostal muscles. There is some experimental evidence to show that the external intercostal muscles act during inspiration. The fibres slant from above downwards and forwards, and shortening, raise the ribs. The fibres of the internal intercostals, on the other hand, slant from above downwards and backwards, and shortening, lower the ribs. The two, acting together, make rigid the thoracic wall. The intercartilaginous fibres act with the external intercostals. The purpose of the movement of the lower ribs is primarily to expand the lower lobe of the lung. In this action the diaphragm is intimately concerned, aided by the ilio-costalis, and the action of the external intercostal and the interchondral muscles. The antagonistic muscles are the external oblique, the internal oblique, and the transversalis. During inspiration, owing to the mode of articulation of the ribs, the lateral and anterior part of each moves outwards more than the one above. At the same time, the lower ribs are raised, together with the sternum, so that the net result of the lower rib movement is to increase the transverse and back-to-front diameter of the lower thorax, and with the diaphragm moving downwards, the vertical diameter of the whole cavity.

The first pair of ribs and the manubrium sterni are intimately bound together and form a lid or operculum to the thorax. This lid is articulated behind with the spinal column, in front with the body of the sternum, the manubrio-sternal joint (Fig. 2). During inspiration there is a slight upward movement of the lid, allowed by the manubrio-sternal joint, which causes an expansion of the anterior part of the apex to the lungs. This movement is particularly marked in the thoracic type of breathing. In persons with ill-developed chests there is but little movement here. The posterior part of the apex of the lung is but little affected by the movement of the operculum, its expansion being secured by diaphragmatic breathing. Inspiration is, therefore, a very complex act, and it is owing to the complicated nature of the movements concerned that the lungs are divided into lobes. The upper ribs are chiefly concerned in the expansion of the upper lobes, the lower ribs in the expansion of the lower lobes, the diaphragm promoting the expansion of the whole lung. As already stated, expiration is controlled by muscular action; generally speaking, the extensibility and elasticity of the thorax are to be regarded as factors in producing expansion or compression of the lung only when the ribs pass into extreme inspiratory or expiratory positions.

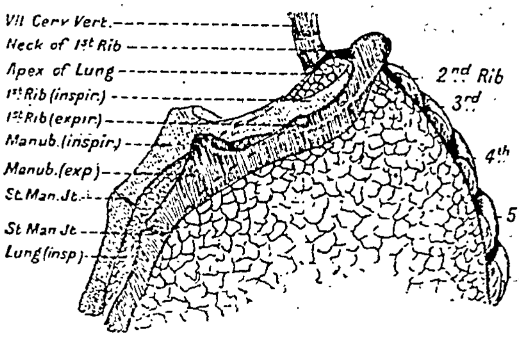

FIG. 2.—Diagram to show respiratory movements of the first pair of ribs and manubrium sterni, and the effect of these movements on the expansion of the apex of the lung (Keith).

MECHANISM OF CIRCULATION.

The mechanism of the circulation has been so contrived that it remains constant and efficient, not only in the horizontal position, but also when the living animal is ceaselessly shifting the position of his body. The hydrostatic influence of gravity had a most important bearing on the evolution of the mechanisms which control the circulation. In the upright posture the blood under the influence of gravity continually presses downwards, and would sink if the veins and capillaries of the lower parts were sufficiently extensile to contain it and there were no mechanisms to counteract the effect of gravity.[9] [10] Such is actually the case in the snake or eel; in them, as Leonard Hill has shown, the heart empties so soon as they are immobilised in the vertical posture. This does not occur if the snake or eel be immersed in water, since the hydrostatic pressure of the column of water outside them balances that of the blood within. During the evolution of man there have been developed special mechanisms by which the sagging of the blood to the lower parts is prevented and the assumption of the erect posture rendered possible. In fishes, amphibia, and reptiles there are venous valves for preventing regurgitation of the blood from the sinus venosus into the great veins. In the warm-blooded vertebrates, with the appearance of the diaphragm and the fusion of the sinus venosus with the right auricle, a venous cistern formed by the superior and inferior venæ cavæ and by the innominate, iliac, hepatic, and renal veins, takes the place of the sinus venosus. Six pairs of valves prevent regurgitation from this cistern—namely, those placed in the common femoral, the subclavian, and jugular veins (Fig. 3). The cistern, when filled, may hold some 400 c.cm. of blood. In the liver there may be some 500 c.cm. of blood. This can be expressed into the cistern by abdominal pressure. The portal venous system, when distended, may hold another 500 c.cm., which can be expressed through the portal veins and the liver into the cistern. There is thus a large volume of blood for the heart to draw upon during diastole, and this may be of particular value during the performance of a great

LIBRARY

The Milroy Lectures

ON

RESPIRATORY EFFICIENCY IN RELATION TO HEALTH AND DISEASE.

Delivered before the Royal College of Physicians of London

BY MARTIN FLACK, C.B.E., M.B., B.CH. OXON.,
WING COMMANDER, ROYAL AIR FORCE MEDICAL SERVICE.

LECTURE I.*

Dr. Milroy's desire in establishing these lectures was to "promote the advancement of medical science along with the interests of philanthropic benevolence and of social welfare."[1] As showing what was in his mind he states in the codicil to his will that—

> "*there is a vast amount of protracted malaise and suffering, disablement or lessened capacity for industrial work, and often, too, of slow but eventually fatal sickness* in almost every region of the world due to the multiform class of the cachexiæ or those chronic constitutional diseases which consist, according to Cullen's definition, in a depraved state of the whole or of a considerable part of the habit of the body without any primary pyrexia or neurosis combined with that state."[1]

It is my hope to show that this state of physical inefficiency is frequently associated with a state of respiratory insufficiency. Bearing in mind the vast amount of material at my disposal, it will be necessary for me to confine myself to certain lines of thought. In doing this I shall endeavour as far as possible to bear in mind the advice offered by Dr. John Brown.[2]

> "The physiology to be *taught* in schools and to our clients the public should be the physiology of common sense rather than that of dogmatic and minute science ...... and will make them understand enough of the fearful and wonderful machinery of life, to awe and to warn, as well as enlighten."

There can be no doubt as to the necessity of enlightening the public in regard to the correct application of physiology *to daily life*. The aims of *Dr. Milroy for the advancement of social welfare can therefore best be met by the exposition of views in such a form that they can be readily transmitted to the public and be easily understood by them.* The *views I wish to put forward in these lectures are the* result of my experience in the Medical Service of the Royal Air Force, where I have had the *opportunity* of testing and extending the observations *made by two of my former teachers*, Arthur Keith and Leonard Hill, to whom I take this opportunity of *acknowledging* my very great indebtedness. Their work has already been ably set forth by them, but I *desire to insist* upon the fact that it has been too little applied and that now is the time for its *application to* everyday life.

The publication of the figures of the war physical census *emphasises this point.*[3] During the 12 months preceding the armistice 2,425,181 medical examinations were conducted, the men being graded as follows :—

		Actual grading.		Keith's standard.
Grade I.	..	871,769 (36%)	..	1,697,595 (70%)
Grade II.	..	540,276 (22–23%)	..	485,010 (20%)
Grade III.	..	756,859 (31–32%)	..	181,902 (7·5%)
Grade IV.	..	250,280 (10%)	..	60,617 (2·5%)

In other words out of every 9 men called up 3 were placed in Grade I., 2 in Grade II., 3 in Grade III., and 1 in Grade IV., a figure sadly below what might be expected from a healthy nation. This is *seen* when comparison is made with Keith's standard, which is based on the law worked out in regard to *other* human measurements by Karl Pearson and his pupils. *Instead of every 1000 men examined yielding on the* average 700 Grade I., 200 Grade II., 75 Grade III., *and 25 Grade IV., the actual yield is* 359 Grade I., 226 Grade II., 312 Grade III., and 103 Grade IV. *The position may be summarised by saying that in* round numbers our physical census showed a shortage *of 825,000 Grade I. men, an excess of 61,000 Grade II.* men, and the alarming excess of no less than 575,000 *Grade III. men, and 190,000 Grade IV.* men.

When dealing only with the youths of 18 it might be expected *that the proportion of fit*, and consequently the index of fitness, would be considerably higher. Instead *of this it was found among the youths* who became 18 years of age during 1918 that there was: (*a*) A *deficit of nearly 13,000 Grade I.* youths among the 260,000 examined : (*b*) an excess of over 6000 Grade IV. youths, or, *in other words*, almost double the number of youths "totally and permanently unfit for any form of *military service*" which there should have been, judging by Keith's standard.

CAUSES OF DEFICIENCY.

As the official report says, "*Such a conclusion can only be regarded as exceedingly disquieting, and in itself throws a lurid light upon the effects of our civilisation upon the adolescent population.*" The chief causes given for this deficiency were : (1) *Poor* physique and presence *of physical defects* ; (2) tuberculosis ; (3) diseases and degeneration of the heart and blood-vessels, in *many cases due to various* infective conditions.

With regard to the *first* group, *a considerable* amount was due to preventable conditions in early life such as dietetic errors. *Apart from these*, however, a very important cause of defects of physique and of degeneration was the effect of *occupation* on workers. I quote from a lecture by Sir James Galloway[4] :—

> "*One of the most striking features of the report of grading* in the industrial districts is the rapid fall of the numbers of young men who could be placed in Grade I. at the age of 18 years compared to the numbers who could be placed in the same grade on being examined four or five years later."

This remark applied particularly to the young workers in the textile industries, *both in cotton and* wool. A medical officer in regard to the south-eastern areas of *Lancashire noted that the average* man there was for military purposes an old man before he reached the age of 40. *Of* 200 youths of 18 to 20 years of age examined and rejected in the north-western region of England *no fewer than* 85 were rejected on account of poor physique.

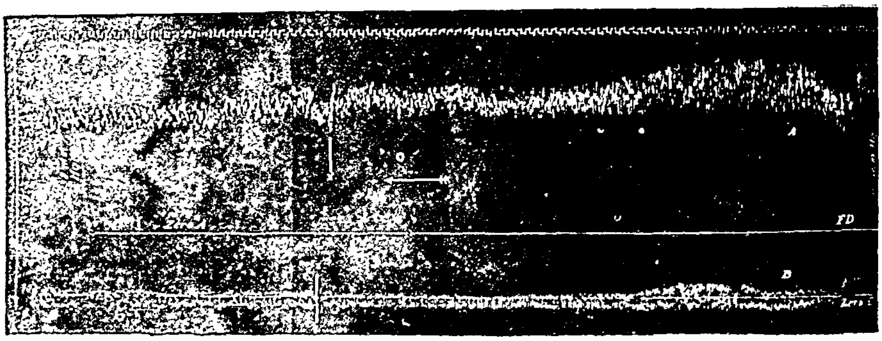
The second great cause, as *I have stated*, was tuberculosis. In London 3·1 per cent. of 160,515 examinations made were placed in Grades III. *and* IV., 2·6 being for tuberculosis of the lungs. As the result of 66,000 examinations made in *Liverpool from* Nov. 1st, 1917, to Jan. 31st, 1918, which were carried out in close association with the medical officer of health and his officials, about 1·75 per cent. were rejected on account of tuberculosis, the striking *fact emerging* that of 277 *cases proved to be tuberculous* 218, or 78 per cent., were previously unknown to the *health authorities*.

The third great cause noted was disease and *degeneration of the heart and* blood-vessels. Included in this category are the various forms of heart disease *due to rheumatic* inflammation of the heart. On these I do not dwell except perhaps to point out that *I hope to show* efficient respiration to be of great value in aiding to preserve the physical efficiency of *such cases*. On the other hand, one of the most important forms of circulatory troubles was venous varix *in some* form. The amount of this was surprising even to experienced medical men, especially in industrial districts and among older men. Varicosity of the veins of the lower extremities to an extent sufficient to disable or be dangerous was found to be very common. It may be pointed out that such diseases are largely associated with deficiency of the respiratory mechanism.

---

* Lectures II. and III. will be published in subsequent issues of THE LANCET.

great splanchnic area and of the musculature of the abdominal wall is lost, and the capacity of the abdominal vessels is thus greatly increased. On the animal, when lying in the horizontal posture, the total effect is a considerable fall of arterial pressure, and a marked diminution of the respiratory undulations of pressure; in the vertical feet-down posture, the arterial pressure falls rapidly, and may reach zero; the circulation is then at an end. Under the influence of gravity the whole of the blood collects in the great abdominal veins; it can pass rapidly through the dilated arterioles, there is no mechanism left for filling the heart, and the latter, empty of blood, continues to beat to no purpose. If the abdominal wall be compressed with the hand (B, C, Fig. 4), the capacity of the veins and splanchnic area is reduced, the right heart is once more filled with blood, the arterial pressure rises, and the circulation is renewed. On taking off the hand, the heart once more empties, the arterial pressure falls, and the circulation again ceases. When the animal is returned to the horizontal position, the influence of gravity is abolished, and the circulation becomes re-established. The effect of compression of the abdomen in the horizontal position is also evident (B, C, Fig. 5) but slight. In the feet-up position the aortic pressure rises under the influence of gravity, returning to normal as compensation takes place or when the horizontal position is resumed (Fig. 5). Such experiments prove that in the anæsthetised animal there are two chief compensatory mechanisms by which the hydrostatic effect of gravity is overcome—namely, the vaso-motor mechanism of the arterioles and the respiratory pump.



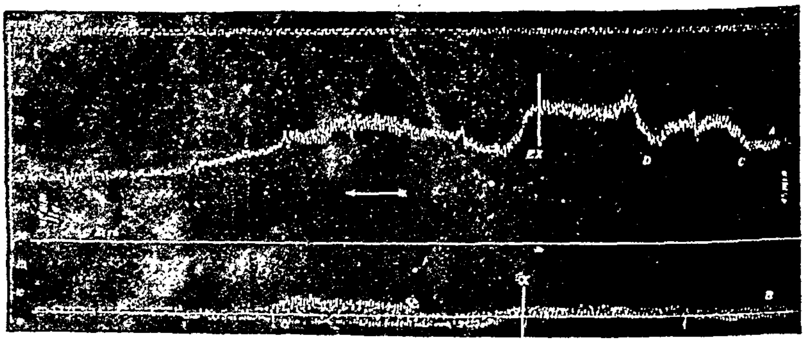


FIG. 6.—To show effect of gravity upon the circulation: carotid and superior vena cava pressures of dog (Hill). F D = Animal turned into feet-down position with cannulæ in axis of rotation. The arterial pressure fell in 50 minutes from 110 mm. Hg to 42 mm. Hg. From C to E X animal was immersed in a bath which was deepened to chin at D. Note increased effect of respiration on venous pressure after F D and again after bath. Note also fall of pressures at F D, and compensatory rise of arterial pressure, which gradually weakens.

COMPENSATORY MECHANISMS.

The vaso-motor tone of the arterioles splanchnic area can be abolished, without interference with the respiratory mechanism, by section of the splanchnic nerves through a lumbar incision. The result of this procedure in the vertical feet-down posture is that the arterial pressure falls very considerably; but, nevertheless, the circulation may remain efficient, on account of the action of the respiratory pump. By greatly increased respiratory movements, combined with powerful abdominal compressions, the diastolic filling of the heart is maintained and the velocity of flow through the splanchnic capillaries checked. Withdrawal of the support of the abdominal muscles by a crucial incision of the abdominal wall leads to dilatation of the splanchnic vessels, and the pressure falls to a further extent. Finally, opening the thorax causes the pressure to fall to zero and the circulation ceases. By compression of the abdomen, or by a return to the horizontal posture, the circulation can be once more renewed. Such an experiment shows that the respiratory pump can compensate for the influence of gravity when the vaso-motor mechanism is paralysed. The respiratory pump can be paralysed by itself, and without damage to the vaso-motor mechanism, by the injection of curari. The power of the heart may then be sufficient by itself to maintain the circulation in the feet-down position, so long as the capacity of the abdominal vessels is kept under control by the vaso-motor nerves.

In man measurements of arterial pressure likewise reveal the effect of gravity upon the circulation.[11] In a normal man standing upright the pressure in the post-tibial artery in the leg is higher than the pressure in the brachial artery by the height of the column of blood which reaches from one artery to the other, about 70 mm. Hg. (See Table I.)

In changes of posture, then, the pressure in the brachial artery—that is, in the root of the aorta—is maintained at practically a constant height by the tone of the splanchnic arterioles and action of the respiratory pump. If the splanchnic arterioles are in an efficient state of tone, and if the abdominal veins are supported by the tone of the abdominal walls, then the splanchnic vessels will not dilate under the hydrostatic stress of gravity. The nervous mechanism involved is probably of the simplest nature, for if the arterial pressure suddenly rise or fall at the moment of change in posture, the bulbar centres are thereby either directly or reflexly excited to increased or decreased activity. A sudden fall of arterial pressure provokes acceleration of the heart, amplified respiration, and increased vaso-constriction. A sudden rise of pressure, on the other hand, provokes a slow heart, shallow respiration, and vaso-dilatation.

When the compensatory mechanism is abolished by destruction, exhaustion, or inhibition of the bulbar centres the circulation fails and becomes inadequate to maintain life in the vertical posture. The blood passes into the capacious reservoirs of the toneless abdominal veins, the heart empties, and the

CORRECT EXPIRATION.

Just as correct inspiration is important so also is correct expiration. If inspiration be correctly coordinated, correct expiration naturally follows; this consists of a contraction of the abdominal muscles, especially those of the upper part of the abdomen together with a reposition of the ribs by virtue of muscular action. The fact that expiration is a muscular act must be emphasised. Inspiration and expiration are due to the coordinated action of groups of antagonistic muscles. When the leg is flexed, as Prof. Sherrington has shown, both the antagonistic flexors and extensors come into action in order to produce a finely coordinated movement. So in the respiratory movements the muscles of inspiration and expiration are antagonistically concerned. In inspiration, the inspiratory muscles in coordinated fashion overcome the expiratory; in expiration the expiratory overcome the inspiratory. From the beginning to the end of the movement each muscle concerned is balanced, steadied, and controlled by the action of its antagonist.

Reference to text books of physiology show that in general the act of quiet expiration is regarded as a non muscular act due to elastic recoil of the expanded lung and the return of the chest by its own weight. This view is undoubtedly based upon the classical work of Dr. Hutchinson[5] published in 1835, and, as Prof. Keith points out, is based upon an error of observation. Michael Foster,[6] in his text book, writes as follows:—

> In normal easy breathing expiration is in the main a simple effect of elastic reaction. By the inspiratory effort the elastic tissue of the lungs is put on the stretch; so long as the inspiratory muscles continue contracting the tissue remains stretched, but directly the muscles relax the elasticity of the lungs comes into play and drives out a portion of the air contained in them. Similarly the elastic sternum and costal cartilage are by the elevation of the ribs put on the stretch; they are driven into a position unnatural to them. When the intercostal and other elevator muscles cease to contract the elasticity of the sternum and costal cartilage causes them to return to their previous position, thus depressing the ribs and diminishing the dimensions of the chest. When the diaphragm descends, in pushing down the abdominal viscera it puts the abdominal wall on the stretch, and hence when at the end of inspiration the diaphragm relaxes the abdominal walls return to their place, and by pressing on the abdominal viscera push the diaphragm up again into its position of rest. Expiration then is in the main simple elastic reaction, but there is probably some, though possibly in most cases a very slight, expenditure of muscular energy to bring the chest more rapidly to its former condition. This is, as we have seen, supposed by many to be afforded by the internal intercostals acting as depressors of the ribs. If these do not act in this way we may suppose that the elastic return of the abdominal walls is accompanied and assisted by a contraction of the abdominal muscles.'

It will be seen that active expiration is allowed to be a supposition. Evidence will be adduced later to show that it should be regarded as a necessity, if properly coordinated efficient expiration is to take place.

THORACIC ANATOMY: EXTENSIBILITY OF THE LUNG.

To understand properly the movements concerned in the processes of inspiration and expiration, certain anatomical details in regard to the bony framework and the musculature of the thorax have to be considered. The varying extensibility of different parts of the lung has also to be borne in mind.[7] In the act of inspiration, owing to the varying degree of extensibility of the different structures of the lung, the organ expands in the manner of a Japanese fan—least in the neighbourhood of the great vessels and bronchi (the root of the lung), most in the outermost zone just beneath the pleura (subpleural zone). The infundibula are the essential distensible elements of the lungs. They vary in size in these different zones of the lung, being largest in the subpleural zone and smallest at the root of the lung (Fig. 1). The distensibility of any part of the lung depends upon the number and size of the infundibula in that part. The lungs do not expand equally in all directions; the two surfaces which are most expanded are the diaphragmatic and the sterno costal, or ventro lateral. In general, the apical surfaces remain almost stationary. It is only when the lungs are well ventilated that the parts most remote from these surfaces of direct expansion are brought properly into action. In people of sedentary habits, therefore, such parts of the lung tend to fall into a condition of disuse, and receive a poor supply of blood, with its immunising properties. This, as Keith suggests, explains why phthisis so frequently first attacks the apex of the lung.[8] The great fissure of the lung is of functional significance in providing for the adequate expansion of the lung in all its parts.

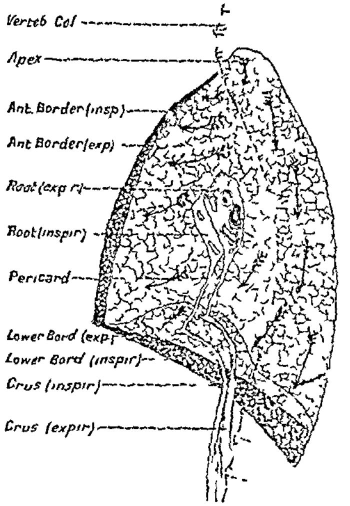

FIG. 1.—Mediastinal aspect of right lung to show respiratory movement of the root (Keith). The crus of the diaphragm is also indicated and its attachment to the root of the lung through the pericardium. Arrows indicate direction of inspiratory movement of various parts of the lung.

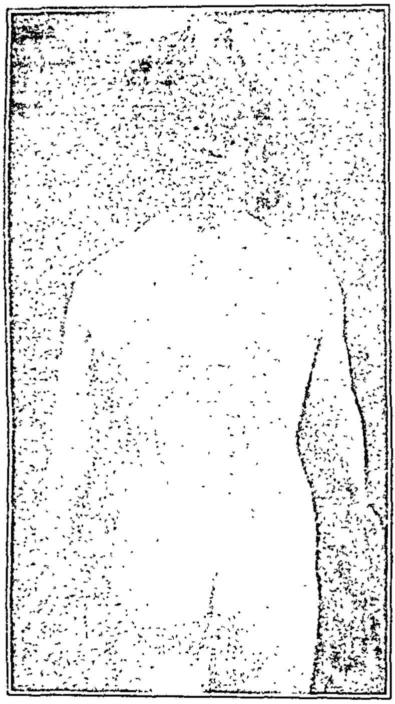
In the inspiratory movement the thorax is, or should be, expanded by the movement of the diaphragm and by the movements of the ribs and rib cartilages. There has been considerable speculation as to the exact nature of the movements performed by the diaphragm. The view commonly expressed is that this muscle, by its contraction, in association with muscles which fix the thorax, opens up the angle which it forms with the thoracic wall, thereby enabling the lung to expand in a downward direction. In such a movement the central tendinous portion is supposed not to participate. After contraction it is assumed that the diaphragm passively returns to the position of rest. Recent study of the diaphragmatic movement by means of the X rays has shown, however, that there is a forward downward movement of the whole diaphragm accompanied by a definite movement of the abdominal viscera.

The diaphragm may be regarded as consisting of two parts: (1) the spinal or crural, from the spinal column and arcuate ligaments to the back portion of the central tendon; and (2) the costo-sternal or anterior, attached to the front and sides of the central tendon and arising by several digitations from the ribs. The arch of the diaphragm rests upon, and is supported equally by, the abdominal viscera, and is at the same time kept constantly applied at the

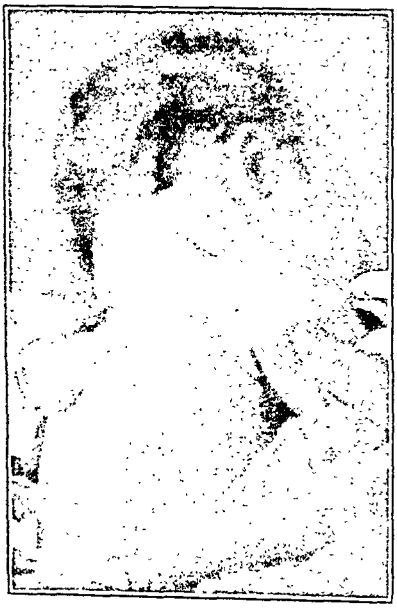
the spine shows a defect of the vertebræ. The third child is the subject of the photograph and had a large meningo-myelocele in the sacral region. This was operated on with the result shown in Fig. 2. The patient is quite well and without deformity, the only symptom present being that she is perhaps unable to hold her urine as long as usual. The fourth and last member of the family has the least defect, which is an exaggerated post-anal dimple.

FIG. 2.



Same patient as Fig. 1, aged 9 years.

FIG. 3.



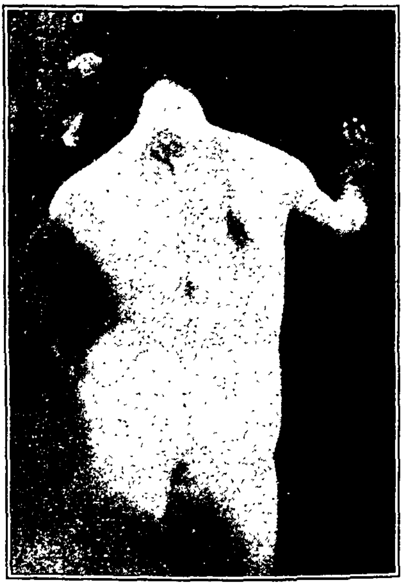
Pedunculated meningocele in the dorsal region. Child aged 2 weeks; a hair field is seen above the tumour.

Various Forms of Spina Bifida.

As before stated, the course of the case depends mainly on the variety of spina bifida present, and whether it is associated with hypersecretion of the cerebro-spinal fluid. Those in which the central canal of the cord opens on the surface do not survive many days owing to loss of fluid or infection. The other cases may die early from ulceration or rupture of the sac with similar consequences.

Spina Bifida Occulta.—Of the varieties of spina bifida the mildest occurs where there is some defect of the vertebral arches without protrusion of the contents. This form, the spina bifida occulta, is commonest in the lumbar region. The defect is often shown by a scarring and depression of the skin in the middle line. This may be covered or surrounded by a hair field (Figs. 3, 4, and 8). In other cases the defect may be covered by a nævoid condition of the skin or a lipoma which forms a definite swelling. This spinal defect may cause no symptoms or may be associated with other deformities at birth, such as club-feet. Later in life various forms of talipes may become evident, trophic lesions may appear on the feet or legs, and an actual paralysis may result owing to pressure or traction on the cord or nerves. In some cases a mild scoliosis or other spinal deformity may develop at the site of the defect.

FIG. 4.



Same patient as Fig. 3, aged 8 years. A hair field partly covers the operation scar. A spina bifida occulta is seen in the lower dorsal region.

Meningocele.—The next in order of severity is the meningocele, which is perhaps the least common. Here, in addition to the spinal defect, there is a protrusion of the membranes, the cavity of which is occupied by cerebro-spinal fluid. The tumour may be pedunculated (Fig. 3) and covered by normal skin, having a narrow pedicle which may become closed and a natural cure result. In other cases the sac may be large, sessile, and thin walled (Fig. 5).

Meningo-myelocele.—This, the commonest type seen in hospital, is associated with a protrusion of the membranes and some part of the spinal cord. It is, as a rule, larger than the former, having a broad base and larger defect in the spine. The coverings may be thin, scarred, and translucent; when the tumour is situated in the lumbar or sacral region the tip of the cord is attached to the summit of the tumour, the cord itself crossing the sac to reach this position. The spinal nerves also cross the sac on either side to reach the intervertebral foramina. In other region muscular effort. Although the aspirating action of the thorax tends to suck this blood into the heart in the upright posture, it is the descent of the diaphragm during inspiration and the efficient contraction of the abdominal muscles during expiration which play the greatest part in forcing blood onwards from the liver and cistern into the heart. The intra-abdominal pressure may be raised considerably on bending or straining. Under such conditions the pericardium protects the right side of the heart from being over-distended with venous blood. If a tame hutch rabbit with a large patulous abdomen be suspended and immobilised in the erect posture, death may result in from 15 to 30 minutes, for the circulation through the brain ceases and the heart soon becomes emptied of blood. If, however, the capacious veins of the abdomen be confined by an abdominal bandage no such result occurs.

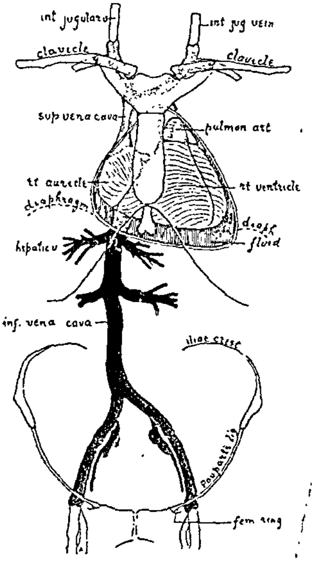


FIG. 3.—Diagram of the venous cistern from which the heart is filled (Keith). The abdominal or infra-diaphragmatic part of the cistern is indicated in black; the thoracic or supra-diaphragmatic is stippled. The heart is compressed upwards and backwards against its attachments.

In a man six feet high the hydrostatic pressure of a column of blood reaching from the vertex of the head to the sole of the foot is equal to 140 mm. Hg. But during the evolution of the upright posture man provides himself with an efficient abdominal belt wherewith to counteract this pressure. The splanchnic arterioles also are maintained in tonic contraction by the vaso-motor centre, and the flow of blood to the abdominal viscera thereby confined within due limits. The veins of the limbs are broken into short segments by valves, and these support the weight of the blood in the erect posture. Every contraction of the skeletal muscles compresses the veins of the body and limbs, for these are confined beneath the taut and elastic skin. Guided by the valves of the veins, the blood is by such means continually driven upwards into the venæ cavæ. In the hanging motionless arm the veins, as seen at the back of the hand, soon become congested. Forcible clenching of the fist or elevation of the limb demonstrates the great influence which muscular exercise and continual change of posture have on the return of blood to the heart. It becomes wearisome and soon impossible for a man to stand motionless. When a man is crucified, immobilised in the erect posture, the blood slowly sinks to the most dependent parts, œdema and thirst result, and finally death from cerebral anæmia ensues. In man standing erect, the heart is situated above its chief reservoir—the abdominal veins. The blood is raised by the action of the respiratory movements, which act both as a suction and as a force pump; for the blood is not only aspirated into the right ventricle by the expansion of the thoracic cavity, but is expressed from the abdomen by the descent of the diaphragm, and the contraction of the abdominal muscles. When a man faints from fear, his muscular system is relaxed and respiration inhibited. The blood, in consequence, sinks into the abdomen, the face blanches, and the heart fails to fill. He is resuscitated either by compression or by being placed in a head-down posture. Men and women with lax abdominal wall and toneless muscles take refuge in the wearing of abdominal belts. To maintain a vigorous circulation and digestion it is necessary to exercise the muscles daily, particularly those of the abdomen.

Leonard Hill studied the question experimentally by passing cannulæ down the external jugular vein and carotid artery into respectively the superior venæ cavæ and aorta of a dog, anæsthetised and placed upon a specially constructed animal table, made to turn round an axis passing through the body at the level of the cannulæ, so that upon turning the table any alteration in the level of fluid in the manometer tubing is avoided. On placing the animal in the feet-down posture, the arterial and venous pressures immediately fall (Figs. 4, 5, and 6). The venous pressure remains down until the horizontal posture is once more assumed, when the arterial pressure rapidly rises again to normal, and it may often be found to rise above normal. The respiratory undulations are frequently intensified while the animal is in the feet-down posture. If left long in the feet-down position the compensatory mechanism gradually fails and the arterial pressure falls. By division of the spinal cord at the level of the first dorsal vertebra, the influence of the bulbar centres on the parts below the section is removed. Abdominal and intercostal respiration is paralysed, and the breathing becomes purely diaphragmatic. The tone of the arterioles of the

motor nerves, anæsthesia, or trophic lesions such as perforating ulcer.

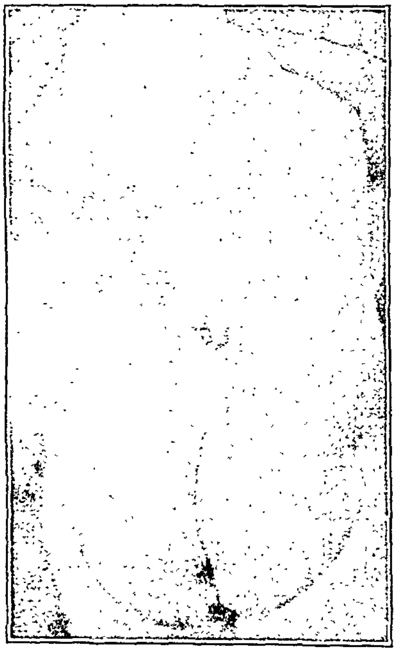
Selection of Cases for Operation.

Even of the cases submitted for one's opinion at hospital only a comparatively small number admit of surgical treatment, which should be limited to the most favourable types, and those who, after operation, are likely and capable of becoming useful members of society. It will, perhaps, be best to discuss each variety separately.

In spina bifida occulta operation is rarely required for the spinal defect. Surgical intervention may be required for the relief of symptoms due to pressure or traction on the spinal cord. In larger defects where static deformity shows itself some form of spinal brace may be necessary or a plastic operation to control this.

In all other cases certain general rules for the care of the patient may be given. It is important to keep the affected part clean, especially when situated in the sacral region, where it is too apt to become dirtied with fæces much to the detriment of its coverings. The surface or tumour should be protected from pressure and abrasion by a careful arrangement of wool round it, and its surface covered by an antiseptic dressing if thin. The lower margin of such dressing may be sealed down by strapping or collodion and so protected from the napkin area.

FIG. 8.



Spina bifida occulta.

The most difficult question now is the selection of suitable cases for operation. Most meningoceles require operation, but as a rule there is no urgency, especially when the tumour is small and has a narrow pedicle. Operation may be carried out at leisure any time during the first year, but parents are usually anxious for the children to be put right as the tumour is a source of anxiety to them and may prevent the child being nursed on its back.

In certain cases operation is contra-indicated. The presence of hydrocephalus should be considered a bar as after operation the head continues to distend —the cerebro-spinal fluid being robbed of a second outlet for the relief of tension. Other cases presenting gross bodily deformity or deformity of limbs not easily rectified should be included in this group. Certain technical difficulties may present themselves in dealing with some of these cases. Owing to the large size of the tumour, and especially if a considerable part is composed of thin translucent membrane, much difficulty may be experienced in covering over the raw surface after removal. In other cases, where a raw spinal area or ulceration is present, sterilisation of this surface may prove difficult, and if not effected leads to wound sepsis and often death.

Cases in which operation is of doubtful use are those of myeloceles and meningo-myeloceles where there is a large raw area. Even if operation is successfully accomplished, deformity is likely to become manifest as the patient grows older, and one such case has complete incontinence of urine and fæces and is a nuisance to himself and his parents. No operation should be undertaken if hydrocephalus is present, but if doubt is felt about this point the head may be measured at regular intervals and its rate of growth noted.

Method of Operation.

In performing the operation the child should be supported on a pillow and lie on its face with the head at a lower level than the trunk, to prevent the undue escape of cerebro-spinal fluid. The first step in the operation consists in exposing the neck of the sac by an encircling incision—designed to leave as much skin as possible for covering over the defect. The neck of the sac should now be isolated—this consists of the dura mater and needs to be cleared of fascia and other coverings obtained from the spinal muscles. In meningoceles, when the neck is narrow, it may be ligatured and the stump returned to the spinal canal; or it may be opened, the redundant sac being then removed and the opening in the neck closed by suture.

In meningo-myeloceles, after the neck is isolated, the sac is opened at one side and the contents inspected. The spinal cord is then separated from its attachment to the apex of the sac and returned with its nerves to the spinal canal. The redundant portion of the membranes is then removed, and the dura and arachnoid closed. In some cases it is impossible to pack the cord back into the spinal canal. In these cases it must be left projecting as far as necessary in the hope that with growth in length of the spine it will gradually be drawn into its proper place.

The third stage in the operation consists in repairing as far as possible the spinal defect. Where a small opening only is present it may, by small incisions undercutting the margins, be possible to draw these together and give sufficient protection to the cord and prevent further displacement of the contents of the canal. In cases where a larger defect is present incisions are made along the outer margins of the erector spinæ muscles through the lumbar fascia. This is dissected up on either side towards the middle line, and the flaps so formed turned over the gap and sutured together. In order to further supplement this covering similar portions of the erector spinæ itself may be used in like fashion. Following this the skin is brought together—a procedure which may require considerable undercutting or even flap formation.

In some cases an osteoplastic repair may be necessary. It has not been so in my cases, but in order to form a bony covering for the defect the spinous processes above and below the gap may be cut across at their bases and turned to meet one another and sutured over the defect. A further possible method is to expose and divide the laminæ of the affected vertebræ on each side and bring them together in the middle line. Where a considerable defect requires filling, and especially if some deformity has arisen or is likely to arise, bone grafting, after the method of Albee, would be suitable.

cerebral circulation ceases There can be no doubt that the control of this compensatory mechanism is one of the most important and necessary functions of the group of bulbar centres—a function which must have been evolved to its highest point, as man in his evolution assumed the erect posture During the course of each day the compensatory mechanism becomes fatigued especially is this so after severe muscular exertion By sleep and rest in the horizontal posture the compensatory power is restored In conditions of neurasthenia of weakness and exhaustion after bodily strain and disease, of shock after severe injury or hæmorrhage, this power may be greatly lessened

TABLE I

Posture	Pressure in mm Hg		Difference in mm Hg	Difference calculated from height of column in mm Hg	Height of column separating armlets in cm
	Brachial artery	Posterior tibial artery			
Horizontal	106	106	0	0	0
Standing	110	165	55	58	54
L posture legs up	115	85	30	33	44
Vertical head down	115	50	65	63	82

A useful clinical guide to the condition of the compensatory mechanism in man is afforded not only *by the pressures in the brachial artery, particularly* the diastolic pressure but by the rate of the pulse on change of posture If the heart greatly accelerates on rising from the horizontal to the vertical position, the mechanism is deficient From the above the importance of the respiratory movements as regards circulatory efficiency is clearly seen The downward plunge of the diaphragmatic piston during inspiration and the inward thrust of the abdominal wall during expiration are necessary for man s efficiency in the upright posture

Finally I would draw attention to the importance of the correct muscular movements of breathing in massaging the abdominal contents The descent of the diaphragm in inspiration the contraction of the abdominal wall in expiration provide massage mechanism which plays an important part in the preservation of the tone of the smooth muscle of the abdominal contents

One of the present day evils is constipation which does not occur when a good tone of the abdominal wall is preserved *Equally as important is the fact* that the state of semi constipation is abolished, the state in which the bowels although acting daily, act only in insufficient fashion without the use of occasional purgatives By what means good tone of the external abdominal *muscles induces good tone of* the smooth muscle is not *sufficiently known, nor* can it yet be adequately explained how conditions affecting directly the tone of the smooth muscle as for example enteritis bring about a relaxation of tone of the external muscles The fact remains however, that good *tone of the muscles constituting* the natural abdominal belt play an important part in preserving a healthy condition of the abdominal contents

SPINA BIFIDA[1]

BY FREDERICK C PYBUS M S DURH, F R C S ENG,

ASSISTANT SURGEON ROYAL VICTORIA INFIRMARY LATE SURGEON HOSPITAL FOR SICK CHILDREN NEWCASTLE ON TYNE

BY spina bifida we mean a congenital defect of the vertebræ, usually the *posterior arch associated,* in most cases with some protrusion of the spinal contents *The defect may involve a large or small area of the spine, but when a tumour is present this* is due to a protrusion of contents due to increase in the intraspinal pressure This increased pressure may be temporary, as such cases can be cured or may undergo spontaneous cure while others are progressive in character and are often associated or followed by hydrocephalus Probably various combinations of these factors account for the production and *different varieties of this condition* This defect occurs in about one in 1000 births and is often incompatible with life, at the best many cases succumb during their first year, and others exist for a time with various accompanying deformities

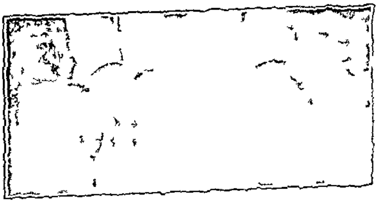
Development of Spine and Spinal Cord

Fully to understand the anatomy of the condition *it is essential to know the method of develop*ment of the spine and spinal cord Briefly it is as follows in the dorsal middle line a groove appears the neural groove, which sinks into the underlying mesoblast and subsequently its edges fusing it *becomes the neural canal This becomes separated* from the surface, the surrounding mesoblast forming *the spinal membranes* Round the spinal cord and membranes *thus formed the vertebræ are developed* Cartilage being *formed round the notochord and being in its turn replaced by bone centres of ossification* appear for the bodies and *posterior arches* The process of ossification for the bodies commences in the mid dorsal region and progresses up and down the spine while the centres for the neural arches commence in the cervical region the process extending backwards so that the lumbar and sacral elements are the last to have a bony roof Development may be arrested at any one of these stages and accounts for the different types *of spina bifida met with* clinically

Spina Bifida as a Family Defect

Spina bifida is met with almost equally in the two sexes and we can only suggest that it is due to some somatic defect *Occasionally it is a family defect* One member of such a family is depicted in Fig 1

FIG 1



Meningo myelocele in a *child at 14 months* a large thin walled translucent sac in the sacral region

Here all four children *had some degree of spinal* defect The eldest died at the age of 18 months with spina bifida the type of which is unknown and with hydrocephalus The second child now aged 10 years has a spina bifida occulta indicated by a scar and depression in the upper dorsal region and by slight scoliosis A photograph of this portion of

II.—*The Special Symptom Sheets.*

Early in our work it became evident that certain well marked symptoms are common to many states of ill-health—for example, pain, exhaustion, &c. It was decided to attempt to differentiate the nature of each of these symptoms: (1) By careful consideration of the associated phenomena present in each case; and (2) by a systematic investigation of their mechanism.

The first step was to decide which phenomena associated with each leading symptom should be systematically recorded. As a result of many discussions sheets were drawn up embodying points considered essential for uniformity and accuracy. These sheets are still provisional and are regularly reviewed from time to time; only by a lengthy experience can they be brought to anything like perfection. All sheets filled up for any one symptom, common to a number of diseased states, are filed together, and compared and analysed. In this way types of exhaustion, breathlessness, headache, &c., characteristic of certain morbid states can be differentiated by consideration of the variety of the associated phenomena present in each case. The details of some of these sheets are recorded below with some comments on their objects and uses. The following is the sheet for recording pain.

Pain.

A.—*Subjective Phenomena.*

(*a*) Regions; (*b*) area and point of maximum intensity; (*c*) radiation; (*d*) character—dull, aching, sharp, lancinating, wave-like, &c.; (*e*) how induced, relieved, and aggravated; (*f*) relation to effort, posture, &c.; (*g*) time of onset and duration.

B.—*Associated Phenomena.*

1. *Subjective.*—(*a*) Faintness; (*b*) giddiness; (*c*) others—e.g., visceral reflexes such as vomiting, frequency of micturition, &c.

2. *Objective* (Physical Examination).—(*a*) Hyperalgesia of skin, subcutaneous tissue, muscle; (*b*) deep tenderness; (*c*) rigidity of muscles; (*d*) cutaneous reflexes: muscular, pilomotor, vasomotor.

Pain as a symptom calls so urgently for immediate relief that its careful investigation is frequently omitted and its diagnostic value lost. That it is induced by stimulation of definite afferent paths is undoubted; were these paths accurately known the seat of origin of their stimulus could be inferred. Direct experiments on animals give little information of the sensations evoked, and elucidation can only be effected by inference from the study of sensory phenomena in man. Pain is, nevertheless, the most useful and often the only symptom determining the locality of an abnormal stimulus. The frequency of reflex or referred pain has been demonstrated, and it is possible in many cases, as a result of accumulation of clinical experiences, to infer the locality of the stimulus. This inference is largely guided by the consideration of the associated phenomena present. The pain sheet has been devised with the object of bringing out the associated phenomena. The character of a painful sensation is of more importance than is commonly believed, the remittent character of pain due to disordered peristalsis of the hollow viscera, and the various qualities ascribed to it by patients, are all of importance, but apart from this the use of the word pain by a patient is frequently misleading. The term is used for any disagreeable sensation, and it should be the aim of the examiner to determine the exact character of the sensation complained of. What is described as pain after food is often in reality a sensation of fullness and distension. The associated phenomena to be specially recorded in this sheet are selected with the idea of differentiating the mechanism disturbed; the pain experienced in heart affections, for example, never seems to be associated with vomiting, while it is common knowledge that vomiting is frequently associated with the intense colics which occur in disease of some of the abdominal organs (gallstones, renal calculus, uterine contraction, &c.).

The following is the sheet for recording exhaustion.

Exhaustion.

Sensation of Exhaustion.—(1) Time of day felt; (2) variations in intensity; (3) relation to effort; (4) relation to food; (5) relation to posture; (6) relation to rest.

Associated Subjective Phenomena.—(1) Breathlessness; (2) palpitation; (3) giddiness; (4) sweating; (5) nausea; (6) faintness; (7) sinking in epigastrium; (8) chilliness; (9) headache; (10) mental phenomena, depression, loss of memory, irritability, lack of concentration, &c.

Associated Objective Phenomena.—Blood pressure, pallor, flushing, ocular phenomena, tache cerebrale, effect of abdominal compression on filling of jugular vein, reflexes, blood count.

Type of Exhaustion Present.—Exhaustion is one of the commonest sensations of which patients complain, and is frequently the first indication which comes to them of failure of health. Numerous early discussions, devoted to this subject, demonstrated how little is known about this important symptom; but as time went on it became clear, mainly through the researches of Dr. J. Orr, that it may be possible to differentiate certain types of exhaustion and to correlate some of them with certain types of disease. Great difficulty is experienced in locating the tissues to which the sensation of exhaustion is referred. In some cases the feeling of disability is mainly experienced with regard to muscular activity, but in the majority the sensation is more generalised and referable to all parts of the body.

Fatigue is believed to be caused by the action of chemical products upon the neuro-muscular apparatus. In our series of cases of exhaustion there is almost invariable evidence of the presence of toxæmia. It therefore seems possible that exhaustion is due to a process similar to the action of fatigue toxic substances upon nerve cells, nerve endings, or synapses. The present sheet on exhaustion is designed to bring out the associated phenomena present which appear likely to throw light upon the mechanism of its production.

The following is the sheet for recording response to effort.

Response to Effort.

Nature of limiting sensation (see below).

Is tolerance acquired by repeated effort? (Details of this.)

Describe response to (*a*) gentle continued exercise; (*b*) short sharp exertion.

Symptoms associated with limiting sensation: Pain, breathlessness, exhaustion, syncope, palpitation, giddiness, &c. (See special sheets.)

If limiting sensation occurs apart from effort (*a*) is it delayed? (*b*) is it totally unrelated to effort?

Amount of effort producing limiting sensation, with sensation produced: (*a*) On level at usual pace; (*b*) on hill or stair; (*c*) on level with accelerated pace; (*d*) before food; (*e*) after food; (*f*) on warm day; (*g*) on cold day.

Limitation of capacity for work apart from distress.

Present disability increasing, stationary, diminishing, or variable.

Patient's capacity for effort when in good health.

Directions for Study of Response to Effort.

Nature of limiting sensation: Pain, breathlessness, exhaustion, any other.

A. If effort limited by pain: (1) Fill up pain sheet with particular reference to site, radiation, &c.; (2) whether tolerance acquired by repeated effort; (3) if so, note minimum and maximum amount of effort; (4) whether associated with breathlessness or exhaustion; (5) any other associated symptoms.

B. If effort limited by breathlessness: (1) Note if associated with pain or exhaustion; (2) if so, note effect of (*a*) gentle continued exercise, and (*b*) short sharp exertion, on nature of limiting sensation; (3) whether breathlessness occurs, independently of exertion; (4) any other associated symptoms.

C. If effort limited by exhaustion: (1) Fill up exhaustion sheet; (2) note if associated with breathlessness or pain; (3) if so, inquire as to B. (2) above; (4) if exhaustion followed by rise of temperature; (5) any associated symptoms.

D. If effort limited by any other sensation, fill up appropriate sheet.

In all cases.

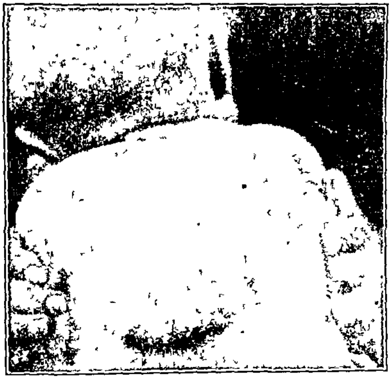
(1) Note amount of effort necessary to produce distress: (*a*) On level going at own pace; (*b*) on hill or stair; (*c*) on

the cord is attached by its dorsal aspect to the top of the sac, leaving the spinal canal to reach this attachment and passing down to the lower extremity of the sac to regain its normal position. In some cases the cord, at this area of attachment, may open on the surface or present a reddened and apparently ulcerated surface as is shown in Fig. 6. When the cord opens on the summit of the protrusion the condition is really a myelocele.

Syringomyelocele.—The fourth type or syringomyelocele resembles the above in many particulars, but the central canal of the cord is dilated, the distended cord occupying a portion of the sac. One such example was found at operation, and the finger could be passed readily into the dilated central canal.

Myelocele.—The myelocele is the gravest defect of the series. Here the posterior part of the spinal canal and cord is undeveloped and the central canal opens directly on to the surface at its termination or for a considerable part of its length. Indeed, the condition resembles the earliest stage of its development. The defect is seen as a red and vascular area at the bottom of which the central canal can be found. Naturally these cases do not survive long.

FIG. 5.

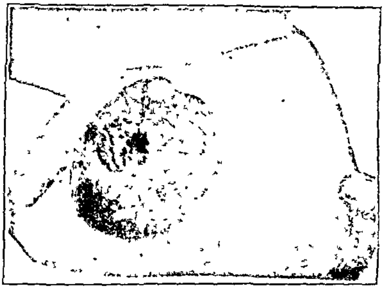


Large meningocele in the dorsal region.

Diagnosis.

The diagnosis is made on the history and appearances of the swelling. The condition is congenital, it is situated in the middle line over the spine, the surface is scarred or vascular, while in most cases a swelling is present. The covering may be natural skin, and the consistence of the swelling shows it to contain fluid. It has an impulse on coughing or straining, and if necessary fluctuation can be obtained between the tumour and the anterior fontanelle. To determine the variety present may be more difficult. Pedunculated tumours are usually simple meningoceles and are covered by normal skin. If the tumour is large, has a broad base, with scarring on the surface and transculent walls, a meningo-myelocele is probably present. In some of these three definite zones can be recognised, the apex a red vascular zone, surrounded by a thin translucent area, while at the base this merges into the skin of the back. (Fig. 6.) It is impossible to determine the syringomyelocele from external examination. The character and extent of the spinal defect can, in some cases, be determined by palpation, for the defect can be felt at the margins of the tumour. In other cases the protrusion overlaps the defect to such an extent that its edges cannot be detected. A radiograph will, however, reveal the defect if it is thought necessary to have this information. There are two conditions which may be mistaken for spina bifida. The first is a nævus in the middle line of the back, an unusual position. It can be lifted off the deeper structures and is not associated with any spinal defect. The second condition is that of sacrococcygeal tumour. Here the tumour may be solid or possess translucent cysts, but is situated at the termination of the spine, and involves the perineum and coccyx. No impulse is present on coughing or straining, and no fluctuation can be obtained with the anterior fontanelle. It should be mentioned that very rarely there may be a defect in the anterior part of the vertebræ, and that a protrusion may take place forwards into the pelvis or abdomen.

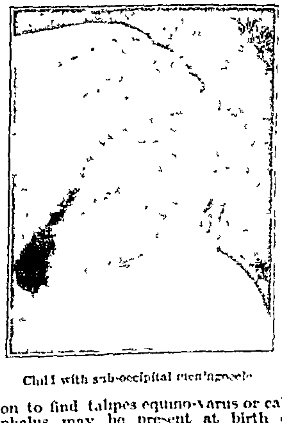
FIG. 6.



Meningo-myelocele in the sacral region showing a "raw area" in the centre of the swelling.

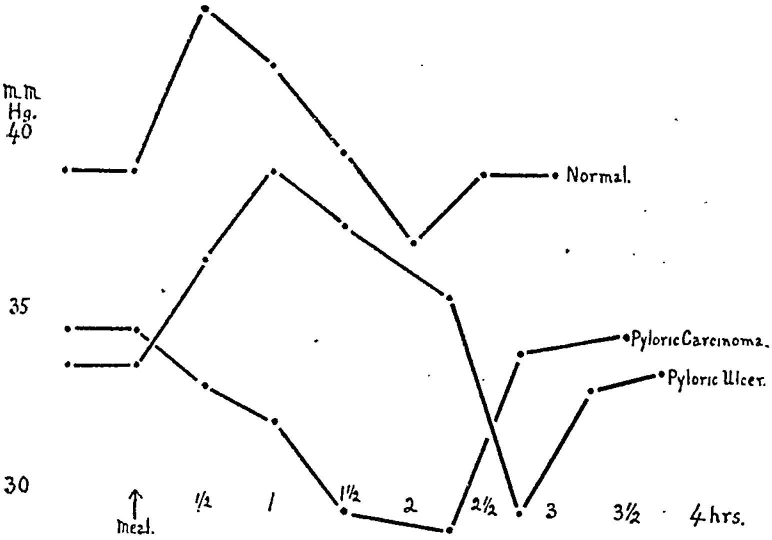
Congenital Malformations Accompanying Tumours.—In addition to a local tumour certain other congenital malformations may be present. Scoliosis may accompany the spinal defect, while it is not uncommon to find talipes equino-varus or calcaneus. Hydrocephalus may be present at birth or may supervene shortly afterwards and is the complication most to be feared. It has been mentioned that later certain nervous phenomena may appear such as paralysis due to involvement of the

FIG. 7.



Child with sub-occipital meningocele.

follows. Before the patient's breakfast two samples of alveolar air are collected. The patient expires as forcibly as possible into a long rubber tube; after full expiration he closes the end of the tube with his tongue, and a sample of the last air expired is drawn off from the tube into an evacuated receiver attached to the tube as near the patient's mouth as possible. Two samples are collected in this manner, one taken at the end of an inspiration, one at the end of an expiration. The percentage of CO_2 is then determined by analysis with Haldane's apparatus, the mean of the inspiratory and expiratory samples being taken to represent the tension. The patient then has a standard breakfast, composed of a glass of milk and three rusks. After the meal samples are collected and analysed quarter-hourly until the tension remains constant for two readings.



Three typical curves of alveolar CO_2 tension.

Conditions giving Characteristic Curves.

We find that the following conditions when investigated by this method give curves which are at least as characteristic as those obtained by the fractional test-meal: (1) hyperchlorhydria, (2) hypo- and achlorhydria, (3) rapid emptying of stomach, (4) carcinoma of stomach, (5) pyloric ulcer. When a result is obtained indicating the presence of any one of the first three of these it is important to remember that very wide variations in gastric secretion, ranging from extreme hyperchlorhydria even to achlorhydria, occur in quite healthy persons.[2 3]

Advantages of the Method.

The above curves provide examples of the very definite pictures yielded by this method in various pathological conditions. The following advantages distinguish it from other methods in use:—

1. The analysis of alveolar air does not cause the subject any discomfort whatever, hence it can be employed even in patients in whom nervousness, or some other general condition, forbids the passage of stomach tubes of any type. The insertion and retention of the stomach tube in the fractional test-meal produces in some few persons considerable discomfort, with nausea, retching, and salivation. It is difficult to believe that gastric digestion follows its usual course under these conditions; hence in such persons the test-meal must give misleading results. In the method described in this paper, on the other hand, the patient, if not informed, would not even know that his digestive system was under examination.

2. The method gives an index of the *total* amount of acid or alkali being secreted from the blood by the gastric or other digestive glands, and hence is independent of neutralising factors such as mucus and regurgitation which affect ordinary gastric analyses.

3. It gives a measure of secretory activity below the pylorus as well as that of the stomach.

4. The form of test-meal is immaterial provided that a fixed standard be selected, allowing comparisons with the curve shown by normal persons after the same meal.

A paper is in preparation in conjunction with Dr. Bennett dealing with a large number of pathological cases in which the results obtained by this method will be shown to be parallel with those obtained by the fractional method of gastric analysis.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF
MALIGNANT PUSTULE WITH MULTIPLE LESIONS.

By R. T. Grant, M.B., Ch.B. Glasg.,
SENIOR ASSISTANT PHYSICIAN, CITY OF GLASGOW FEVER HOSPITAL, RUCHILL.

The following case is somewhat similar to one reported by Dr. W. T. G. Davidson in The Lancet of Jan. 19th, 1918 (p. 104), and is of interest in that it repeats several of the unusual features described by him.

K. E., a butcher, skinned on Jan. 22nd a bullock, which the following day was found to have died of anthrax. On hearing of this K. E. had his shirt and underclothes disinfected and washed his arms in disinfectant. He did not, however, have his outer clothes disinfected. On the 30th a small pimple appeared on the back of his right hand between the thumb and first finger. It was very itchy and irritable and there was a thin clear discharge from it. Condition was not diagnosed as anthrax until Feb. 2nd when the patient was admitted to this hospital.

On admission he was found to have a typical malignant pustule on the dorsum of the right hand between the first and second metacarpals, measuring half an inch in diameter and showing central eschar, ring of vesicles, and surrounded by a zone of inflammatory œdema. There was brawny œdema of the radial side of the hand, but this did not extend above the wrist, nor was there any lymphangitis or enlargement of lymphatic glands of the arm. A second, but much smaller pustule (which had not been noticed by the patient) was found on the radial side of the left forearm at the junction of the upper and middle thirds surrounded by a zone of œdema about five inches in diameter. Two small pimples were noticed lying to the outer and upper side of the latter, but these did not present the typical appearances of malignant pustule and were not surrounded by œdema. No lymphangitis or lymphadenitis of left arm. Patient's general condition was apparently unaffected and there was no pyrexia. Smears from the first and second pustules showed Gram-positive anthracoid organisms and staphylococci, the third and fourth pimples showed staphylococci only. The two pustules were excised on Feb. 2nd, and the patient was given 40 c.cm. of Sclavo's serum subcutaneously into the abdomen. On the following morning as there was some spread of the œdema on the left arm a further dose of 20 c.cm. of serum was administered. Patient made an uninterrupted recovery.

STUDIES FROM THE ST. ANDREWS INSTITUTE OF CLINICAL RESEARCH.

II CASE-TAKING METHODS.

By J. H. P. PATON, M.B , CH B. EDIN.

Introduction.

IN 1918 Sir James Mackenzie was appointed consulting physician to the St. Andrews Cottage Hospital. In that capacity he at once instituted weekly out-patient clinics, at which he saw patients brought to him by medical practitioners in the town These clinics took the form of meetings which attracted not only local practitioners but a number of doctors from the surrounding district; discussions took place on the special problems which confront the general practitioner, and on the need for systematic investigation of these problems. It became obvious that a vast amount of material for their solution was lost, or could not be utilised, under the present conditions of general practice. As a direct result of these discussions Sir James Mackenzie enlisted the support of all the local practitioners, and plans were drawn up for the creation of an Institute for Clinical Research The idea of founding such an institution had long been present in Sir James Mackenzie's mind, and he had made an attempt in that direction at the London Hospital, but it was found to be impossible to keep in touch with patients where the population was of so migratory a character, and he realised that the plan was only possible in a small town such as St Andrews with a comparatively stationary population.

As a result of his influence several personal friends of his own, who realised the possibilities of the scheme, offered to provide the necessary financial support for its initiation A council was formed, and a building was acquired on lease and suitably fitted up, containing consulting rooms and examination rooms and laboratories for radiology, chemistry, and bacteriology. The Carnegie Trustees made a grant for five years to provide the services of a fully-qualified chemist and also those of a bacteriologist. The general basis of the work of the Institute was set forth in the minute of the first general meeting of staff, held on Sept. 5th, 1919, as follows —

> "The main objects of research would be the early stages of disease, and the work would primarily consist of detailed observation of symptoms and the keeping of careful records Prolonged observation of cases would be carried out in order to discover the significance of early symptoms, and researches would be undertaken with a view of ascertaining the mechanism of their production"

This minute makes clear the two essential needs which justified the establishment of the Institute—namely, (1) The need of obtaining accurate records of the earliest symptoms of disease, at a stage prior to the occurrence of structural damage; (2) the need of following up each individual case from its onset to its termination.

Upon these essentials depends any advance in the early diagnosis of disease and in its accurate prognosis. It is true that the hospital records throughout the country are full of information regarding the symptoms of disease, but a little consideration will show that they cannot be records of those facts with which the staff of the Institute are attempting to deal. Advanced cases and cases of acute illness alone are admitted to hospital wards The symptoms recorded are those of fully established disease; the physician does not see in the hospital ward those early stages of disease which it is our purpose to investigate As soon as his patient has sufficiently recovered to resume work he returns to the care of his general practitioner, and all record of his case ceases. Hospital records do not provide first-hand information of the patient's earlier symptoms, habits, and environment in the stages when the necessary information may be acquired.

In the rush of a busy practice the making of accurate records is extremely difficult, and leisure for classification and analysis cannot easily be obtained. The St. Andrews Institute affords facilities to the general practitioner for making such records, and supplies means whereby when taken they are made permanent and systematically kept, so that information can be drawn from them and incorporated into the general sum of medical knowledge.

The first staff meetings were devoted to the consideration of a general scheme of case taking applicable to early cases of disease The following scheme was ultimately adopted, and a year's experience has convinced the staff of its suitability for the purpose.

I.—*General Scheme of Case-Taking*

Duties of the Doctor—(1) Elicit clearly the sensation which led the patient to the belief that he was ill, (2) elicit other sensations associated; (3) have a clear idea in mind as to the information to be elicited by questions, (4) never leave a particular symptom until fully investigated; (5) use questions suitable to the patient's understanding.

The Patient—(1) Details of main complaint, (2) associated sensations; (3) origin and history of present complaint; (4) general survey of each system or organ by questions, to elicit other associated sensations, (5) previous health; (6) family surroundings, home surroundings, habits, &c , (7) physical examination (*a*) general appearance (physiology, peculiarities of manner, &c), (*b*) physical signs (under systems), (*c*) urine, &c , (8) opinion, (9) treatment; (10) after-history.

Duties of Doctor.

It will be observed that the scheme is prefaced by certain directions of such simplicity that they are especially liable to be forgotten, but essential for detailed accuracy in recording the phenomena present before gross physical changes are perceptible. They differentiate clearly the leading symptom from associated symptoms, and discourage aimless and haphazard investigation In the fourth the complete investigation of every symptom is insisted upon. It was soon recognised by everyone that the doctor's conception of symptoms were in general so hazy that steps must be taken to obtain a clearer insight. Consequently, although the earlier notes were unsatisfactory, continued investigation into the nature of symptoms is rendering these notes daily of more value.

The Patient

It was early realised that for successful inquiry into the patient's sensations the element of possible suggestion by the examiner must be eliminated. Simple inquiries make clear to the patient that his own sensations of ill health are what we desire. It is the examiner's duty tactfully but firmly to suppress the numerous suggestions emanating from relatives and friends that appear in the patient's story at this stage Many pertinent symptoms may have been omitted by the patient as being of no importance; these should be elicited by careful inquiry. In order that the examiner may carry this out in an orderly and logical manner, it is essential that he should have previously obtained some general idea of the origin and history of the complaint. This, then, is taken before proceeding to the systematic inquiry into symptoms present (No 4) The remainder of the scheme proceeds upon conventional lines, but special care is taken to note all details in regard to family history, environment, diet, occupation, &c , factors which there is every reason to believe are frequently germane to the development and perpetuation of ill health

Perhaps the most essential part of the scheme is that dealing with after-history. Arrangements are made to ensure that each patient will be again seen from time to time, and the records of his condition and any subsequent illnesses are added to the case. In this way in the course of years the elements of a scientific system of prognosis will be built up—prognosis, that is to say, based upon the outcome of actual cases, and not upon the vague fears engendered by abnormal phenomena of whose significance we are ignorant.

swollen and covered with a circular patch about the size of a shilling. No gland was palpable, but there was some tenderness at the angle of the left jaw. A swab, taken and sent to the city analyst, was reported negative. Four days later, as the membrane appeared very resistant to local treatment, a second swab was taken, which was also reported negative. The membrane disappeared on the twelfth day, having apparently yielded to frequent applications of glycerine of tannin. On the 21st day the patient's friends noticed that the voice had become distinctly nasal, and two days later she noticed for the first time that liquids returned through the nose. Nasal and pharyngeal swabs were now taken, and these were once again pronounced to be negative. On three separate occasions the urine was examined and no albumin found.

There was an epidemic of diphtheria in the town at the time, but the failure to isolate the bacillus on three separate occasions, the strict localisation of the membrane to the tonsil, the absence of albuminuria and glandular enlargement, would justify one in pronouncing the case as non-diphtheritic tonsillitis.

Exeter.

A CASE OF SCURVY.

By R. S. McCLELLAND, M.D. EDIN.

SCURVY is sometimes seen among children in the British Isles to-day, but among adults it is very uncommon. The following case is therefore of interest.

B. C., a collier, aged 40, came to my surgery on July 29th of this year and complained that his teeth were bleeding. He looked ruddy and sunburnt, as most of our colliers are now. His breath was offensive, many of the teeth were carious, and blood was oozing out from the swollen and spongy gums. As fast as it was wiped away from the necks of the teeth it reappeared. Thousands of petechial ecchymoses were to be seen on the limbs and trunk. There were faint systolic murmurs in all the cardiac areas with a pulse-rate of 100, and a normal temperature. There was no albumin in the urine. The patient was seen on August 2nd, 4th, and 6th; the bleeding from the gums continued, while he also complained of weakness and headache. On the evening of the 6th he became unconscious. Deep coma, with stertorous breathing followed; and he died early on the 7th. Late on the 6th it was noted that the pupils were equal, but the right arm was very flaccid. Patient called vegetables "pig's food," and appears to have lived principally on bacon, bread, and tea.

It is not likely that members of the present Polar expedition will be attacked by scurvy. Modern knowledge has practically removed the dangers which in former times constantly attended ocean-going ships in this respect. Some idea of the ravages of scurvy may be gained from the losses sustained by Anson in 1740. The Admiralty, finding themselves short of fit men, ordered Anson to take with him 500 out-patients of Chelsea Hospital on his voyage to the South Seas, assuring him that these were "the properest men that could be employed on this occasion." Many of these elderly seamen escaped, but 259 were finally collected and marched on board. Not one returned. The "sea-scurvy" gripped them, their wounds reopened, their fractures recurred, and they died of wounds received a generation before. When Anson counted his men at Juan Fernandez he found that 626 had died out of a total of 961. It was Captain Cook who first realised the immense importance of fresh vegetables, fruit, and cleanliness, and much of his great success was due to the way he looked after his men. The moment signs of scurvy appeared he would fly from the Polar ice to warmer weather, and refit at some favourite island. Cook was fortunate in that Anderson, who in 1776 sailed with him as surgeon, appears to have been a very able man.

Dowlais, Glam.

FOOD POISONING AT CLITHEROE.—Between 50 and 60 cases of food poisoning, with one death, due it is believed to the consumption of potted meat-paste, have been reported to the health authorities in Clitheroe, Lancs, and neighbourhood. The first case was notified on Sept. 4th, the others in rapid succession. A representative of the Ministry of Health is investigating the outbreak.

Reviews and Notices of Books.

TUBERCULOSIS.

Tuberculosis in India: Its Prevalence, Causation, and Prevention. By ARTHUR LANKESTER, M.D., Officer for Tuberculosis, Government of India. London and Calcutta: Butterworth and Co. 1920. Pp. 317. 10*s*.

MANY books on tuberculosis give the impression that the author has set out on his task with that generous disregard for accuracy and detail which characterises the after-dinner speech. Dr. Lankester's book is in striking contrast to this type of literature; he has combined a great mass of detail with a broad and comprehensive survey of the main problems, and the result is a work which will prove a valuable source of information for many years to come. The author's task has evidently been complicated by his having not only to present new views and observations, but also to overtake and correct erroneous views. Writers on tuberculosis in the United Kingdom have glibly preached that in India surgical tuberculosis is rare, and that this purely fictitious state of affairs is due to the scarcity of bovine-tuberculosis in India. Chevers in his "Diseases of India" declared that he had never seen a case of strumous cervical glands in a native of the plains of India. Dr. Lankester, on the other hand, has found surgical tuberculosis extremely common, and with regard to the relation of surgical tuberculosis to the bovine tubercle bacillus has found their coincidence very rare. In large areas surgical tuberculosis is prevalent, although infection from bovine sources can be definitely excluded. One of Dr. Lankester's most interesting conclusions is that the freedom from tuberculosis enjoyed by cattle in India may be due to a natural resistance, and that it is possible by careful cross-breeding to convey this comparative immunity to other stock.

Although this book contains material collected under the auspices of the Research Fund Association of the Indian Government, the Association is in no sense responsible for the opinions expressed, which are those of Dr. Lankester alone. Having spent 23 years as a medical missionary in India he has brought to his task an intimate knowledge of the sociology of the country, and the value of his scientific appreciation of the peculiarities of the tubercle bacillus is greatly enhanced by his knowledge of its host. On such a subject as compulsory notification, for example, he speaks with authority, and he remarks that in Bombay, where tuberculosis has been a notifiable disease since 1903, notification has been practically a dead letter. In 1913, the notifications of phthisis numbered 84, while the total number of deaths from tuberculosis in this year was 2152. "Consumption is so much feared now in Indian homes that there is a great tendency to conceal its advent, thus the family doctor notifying a case would do so often against the wish of his clients and would lose them at once . . . . notification in India as far as private practice is concerned may be regarded as almost non-existent." Compulsory regulations do not make sanitation more acceptable to the people; and ". . . . in India, where every form of compulsion carries in its train the possibilities of unlawful oppression by subordinates for the purposes of gain, it becomes of special importance to reduce this feature in our campaign to the smallest minimum." In many such passages Dr. Lankester shows an intimate knowledge of human nature, and of the complexity of the problems of tuberculosis as they affect mankind.

Taschenbuch der Diagnostik und Therapie der Lungentuberkulose. Third edition. By Dr. H. GERHARTZ. Berlin: Urban and Schwarzenberg. 1921. With plates. Pp. 296. M.72.

THE most prominent feature of this compact little book is the remarkable tidiness with which the author has arranged its contents. All information capable of tabulation is most conscientiously tabulated; a table level if pace accelerated, and *note nature of distress produced*

(2) Compare amount of effort possible without distress (*a*) Before and after food, (*b*) *on warm and on cold day*, and note nature of distress produced

(3) If no distress complained of on effort, note if there is *any diminution in capacity for work*

(4) Endeavour to estimate for comparison the patient's capacity for effort while in good health

(5) *Note whether present capacity is increasing* stationary or diminishing

The Response to Effort

In addition to other symptoms of disease failure *of health is frequently indicated by a limitation in one* direction or another, of the capacity for effort Breathlessness and pain are the two *symptoms* which appear in patients as the first evidence of cardiac inefficiency Exhaustion, palpitation and giddiness on the other hand, indicate, as a rule, some extracardiac cause, where they occur alone—*apart* from breathlessness or *præcordial pain*—*the* efficiency of the myocardium is not at fault The organ whose efficiency is impaired can be ascertained in *any case only* by consideration of the associated phenomena present The object of the 'Response to effort sheet' is to ensure the recording of such associated phenomena as we at present consider of use in this direction

The impossibility of *fixing* a standard of effort common to all patients was early realised and the individual standard was adopted—i e, the amount of effort that could be undertaken by the individual while in health

This consideration is well *illustrated by the case* of a blacksmith who complained of breathlessness on *climbing a hill or a stair, while he felt no distress on* swinging his hammer in his daily work

It is, moreover true that the capacity of each organ to respond to effort must be *the* ultimate test of its efficiency The inefficient kidney, for example in its advanced *stages produces* symptoms forming a definite clinical picture One must suppose that these *symptoms* represent the terminal phase of a gradual development, and that the *accurate* observation of such cases in their early stages would elicit a definite symptomatology characteristic of the onset of inefficiency No doubt each organ reacts first to some *particular need* of the organism and it lies with the clinician to determine that need and the symptoms which indicate the failure of the organ to meet it

As all organs have periods of quiescence and periods of activity it is manifest that the first sign of failure will be a limitation of the field of response to effort Only by prolonged experience can we acquire a *knowledge of* the details essential for a proper inquiry into the significance of limitation of effort in the case *of each organ* This sheet *therefore even* to a greater extent than the others, is provisional and the directions by which it is accompanied serve to emphasise this

Methods Employed by the Institute for Securing and Investigating Material

Each practitioner on the staff has in the Institute a private room which is reserved for two hours in the day for the examination of research *cases* During the rest of the day he is at liberty to use it as his *private consulting room* He selects cases suitable for research from his private practice and investigates them during his research hours Each member of staff is at liberty to consult any of his *colleagues at* any stage in the case in order that the utmost benefit may be *derived from this privilege* each member of the staff makes himself specially familiar with the literature of one particular branch of clinical medicine—cardiology, neurology, and so on The necessary chemical bacteriological, hæmatological and radiological investigations *are carried out by* the special departments and with each specimen or *case full clinical* notes are supplied to the special department When the notes of each case are completed they are read at a full meeting of staff and discussed in detail Indices are kept *of all symptoms* recorded, and of the leading symptom and provisional *diagnosis of each case*, and arrangements are made to ensure the return of the patient at regular intervals Two full copies of each case are made and filed, one for the use of any member who is interested in any particular case and the other for permanent preservation *in a fireproof safe*

Finally each case is considered in detail by a special committee, whose duty it is to classify and tabulate the findings and to see that all cases are utilised for special investigations If this committee finds that a case taken by one member of staff has some bearing on special work in charge of another it is its duty to inform the latter of the fact This *committee also keeps a note of the date upon* which each patient should return, and at the beginning of each month a list is sent to each clinician of the patients whom he should arrange to see during that month In addition *to* the regular research work and the weekly reading *of* cases *one afternoon in each week* is devoted *to* the discussion of some subject of interest which is chosen by the clinical staff and is introduced by the member who happens to be specially interested in it

A NEW METHOD OF INVESTIGATING GASTRO INTESTINAL SECRETION

BY E C DODDS M R C S L R C P LOND,

ASSISTANT IN BIOCHEMISTRY BLAND SUTTON INSTITUTE OF PATHOLOGY MIDDLESEX HOSPITAL

THE purpose of *the present communication* is to draw attention to a new method of investigating the secretory activity of the alimentary tract in health and disease By taking samples of the alveolar air at intervals after a meal, the writer[1] was able to demonstrate that the tension of carbon dioxide undergoes certain definite changes in response to the amount *of secretion poured* out (*a*) by the stomach, (*b*) by lower portions of the alimentary tract In later work in conjunction with Dr T Izod Bennett [2] it was shown that in normal individuals of varying type the curve of alveolar CO tension so obtained corresponded closely with the curve of secretion of gastric HCl The variations in CO tension may be explained in the following way when acid is removed from the blood during gastric secretion the reaction of the blood tends to shift to the alkaline side This shifting is prevented by retention of the volatile acid CO_2 the tension of which rises in the blood and hence in the alveolar air Later when the alkaline intestinal and pancreatic secretions are poured out the reaction of the blood tends to shift to the acid side and hence acid in the form of CO must be eliminated This is brought about by a lowering of the CO_2 *tension* in the blood and therefore in the alveolar air

This method has now been applied to a number of pathological cases examples of which are given The figure shows three curves obtained (*a*) from a normal individual (*b*) from a case of pyloric carcinoma and (c) from a patient with pyloric ulcer respectively In the curve marked normal it will be seen that after *a meal*, the tension rose *4 5 mm returning to its* previous value in 1½ hours then fell 2 mm, and *finally returned to its original level in* 2¼ hours After this it remained constant The pyloric ulcer curve shows a greater and more prolonged rise (5 5 mm *lasting 2¼ hours*), on the other hand the curve obtained from the case of pyloric carcinoma shows no rise, but a *steady fall of 5 5 mm*

Method of Collecting Alveolar Air

For a description of the physiological processes of which these changes are the expression the reader is *referred* to the article by the writer and Dr Bennett [2] the present *communication* is not intended to be more than preliminary The samples of alveolar air were *collected* by the *Haldane Priestley* method, and the analysis was made with Haldane's gas analysis *apparatus* less delicate methods such as that of Fredericia, proving useless The technique is as admission that he has shown the importance of his subject, and has enriched clinical medicine. Dr. Stekel regards an increase of frigidity and of male impotence as a characteristic of the higher types of cultured people, confirming the view of some English writers that the relative infertility of our upper classes is due to other causes than deliberate restriction of pregnancy. With cultural development purely sensual love has become complicated by motives and tendencies of more subtle nature, which Dr. Stekel analyses with results surprising in their variety though conforming as a rule to psycho-analytical theory. To this theory he gives general adherence, whilst boldly attacking, modifying, or elaborating it in accordance with his personal views, as when, on page 172, he says that the ideas of infantile fixation have been grossly exaggerated and distorted to caricature by the school of Freud, or when he makes the criticism (pp. 221 et seq.), concerning a case treated for a long time by psycho-analysis, that the current sex trouble had not been discovered by the analyst.

The clinical value of his work is in the demonstration of the intimate and frequent association of serious "nervous" disorders with disturbance of the normal sex life, and he accepts with resignation the histories his patients give of long sanatorium "cures" for crippling disorders—hysterias, anxiety states, or compulsory ideas—with neglect of the underlying cause. We cannot, either as scientific men or as healers of the sick, shirk the admission that a great amount of nervous illness is bound up with intercurrent sex difficulties. Dr. Stekel's evidence is not obtained by esoteric psycho-analytical methods, but by simple investigations that can be carried out by any practitioner who has the necessary courage; his teaching in this respect is not new, but he offers such proof that we must either accept his conclusion or reject his clinical histories as unreliable.

Frigidity may be dependent upon causes peculiar to the patient, such as infantile fixations upon another member of the family, early experiences, the idea of self-punishment, the building up of a spurious love as a revenge upon a parent or former lover, or the fear of one's own desires; in short, upon any one of a multitude of causes. But Dr. Stekel makes the generalisation that the ultimate conflict is between "The will to power" and "The will to submission," with a refusal to sacrifice the personality to the demands of sex, a refusal upon which depends the whole modern attitude of the sexes towards each other and to society. "The patients hide 'I will not' or 'I dare not' under 'I cannot.' The unveiling of the 'Inner no' is the task of the psycho-analyst. . . . Sex difficulty shows us the progressive dissociation of civilised man, his division into a 'Willing' and a 'Not-Willing,' his inner tearing-asunder, his play-acting before himself and his battle with himself."

Dr. Stekel's independence and disregard for orthodoxy render useless any criticism of such statements as that on page 460: "There is no doubt whatever that an anti-sexual instinct has developed." Yet one would like to know what he understands by an instinct, for a definition is important even from his point of view. His material has a sociological value; the analyses of unhappy marriages, with the unfolding of the underlying causes, should be studied by all who feel called upon to pass judgment on the ever-increasing number of divorces.

While the material can be commended, the deductions expressed in the last chapter remain a matter for the individual judgment of each reader. They are ultra-feminist and iconoclastic, and the most ardent advocate of divorce reform in this country is left far behind by Dr. Stekel. One regrets that he opens battle on so wide a front; his clinical material is so valuable that it should be separated from views which, whether justifiable or not, are inacceptable to most English readers.

2. The "Beloved Ego" is a book of a totally different kind, containing less reference to sex than one finds in a family newspaper. Although the publishers describe it as "an excellent introduction to the study of psycho-analysis" it is really a psychological study of human error and weakness, and rather a conclusion than an introduction. A vigorous personal note prevails, and, since his thesis is a plea for recognition and guidance of all human desires, Dr. Stekel would perhaps unhesitatingly admit that in the preface his own beloved ego reveals its own self-love and will-to-power. He uses the neuroses to illustrate human failings—the double motive, the fears and doubts of "half-men," the kinship of love and hate, the pleasure that the unlucky dog obtains from his looked-for misfortunes—and confirms the suspicion raised by his other book that in his treatment there is much urging of the patient along the hard road to health, for in this analysis of the failings of mankind he shows more insistence than sweet persuasion.

A short study of "Mali-Mali" (the Malayan neurosis which we call *latah*) is typical of his handling. In this disturbance of the psychic life the sufferer must imitate the person under whose influence he falls; but we cultured people hide our weaknesses and attribute to free-will much which is only the effect of Mali-Mali. Mali-Mali shows us a common human phenomenon under the caricature of neurosis.

Dr. Stekel is a disturber of the peace, but he disturbs it with a cheerful breeziness and an easy style; accepted views are assailed from unexpected quarters, and every page is provocative. How far his philosophy is a legitimate development of psycho-analytical principles is open to question; his views often come near to those of Adler or even Nietzsche though the author's personality will never allow him to be merely the interpreter of the findings of other people.

The lay demand for psycho-analytical literature has led to a flow of books, good and bad; Dr. Stekel's "Beloved Ego," originally published in 1913, was written because he had something to say. In the two books just reviewed he draws a clear line between what the public may be expected to digest and what is requisite for a technical dissertation: psycho-analysis will benefit if this distinction is maintained.

THE LAW OF BIRTHS AND DEATHS.

A Study of the Variation in the Degree of Animal Fertility under the Influence of the Environment. By CHARLES EDWARD PELL. London: T. Fisher Unwin, Ltd. 1921. Pp. 192. 12*s.* 6*d.*

THE author's sub-title gives a clue to the object of his book, which in its main title is totally misnamed. There is no pretence at a study of mortality, and the author himself appears to have realised, at any rate by the time he reached p. 192, that his thesis concerning the fertility of females by no means deserves the dignified title of a law. This thesis is quite adequately summarised on p. 70 as follows:—

> "The variation of the degree of animal fertility in response to the direct action of the environment will be directly proportional to the intensity of the nervous charge until the optimum-point for fertility is reached; it will thenceforward bear an inverse proportion to the intensity of the nervous charge."

It will be seen that the application of this "principle," as the author calls it, depends upon a measurement of the "intensity of the nervous charge." If the reader looks hopefully for some new device for measuring this charge he is fated to disappointment. "The nature of nervous energy" says Mr. Pell, "is very obscure," and we confess that a perusal of the chapter devoted to this subject, and derived very largely from "The Physiology of Bodily Exercise," by Fernand Legrange, does not do much to relieve the obscurity. Starting from so conveniently nebulous a conception it is not difficult to discover the "principle" which derives from it at work in the animal and vegetable kingdoms.

But Mr. Pell has done a service in drawing attention to a subject which badly needs investigation. It is probable, as he says, that the use of contraceptives is an insufficient explanation for large reductions in the birth-rate. A recent article by Mr. Knud Stouman[1]

---

[1] Internat. Jour. of Public Health, 1921, July-August, p. 417.

The anthracoid organisms were isolated and found to be true virulent *B anthracis* The animal inoculation was carried out by Dr J A G Burton of the Royal Infirmary, Glasgow, who reported the organism to be very virulent, *a small dose killing a guinea pig in 30 hours*

The unusual features of this case are (1) the long period intervening between the exposure to infection and the development of the first pustule, and (2) the presence of a second and younger lesion The incubation period usually given for malignant pustule is from one to three days but in this case eight days elapsed before the pustule appeared However, it is possible that although the patient changed his shirt and underclothes, spores had already been transferred from these to his jacket and infection of the skin may have taken place subsequently Clinically the second pustule was much younger than the primary one, and its development is probably to be explained by auto inoculation, as the patient admitted scratching the first one when it appeared *Also to be noted is the* absence of general symptoms and the slight local reaction, although the primary lesion had been present *for four days before admission and the organism* was proved to be very virulent to the guinea pig

TWO UNUSUAL CASES OF

ABDOMINAL TUMOUR

By E C BEVERS, M B, B CH OXON,
F R C S ENG & EDIN,
HON SURGEON, RADCLIFFE INFIRMARY, OXFORD

BOTH these cases are of sufficient rarity in the surgery of the abdomen to warrant their being placed on record

CASE 1 *Large Splenic Cyst* —This patient, who had never suffered from any illness, was the mother of a boy aged 6 and twins aged 4 After the birth of the twins and when she got up she noticed that her figure was not quite as it *used to be, it was a little fuller on the left side than the* right The swelling on her left side gradually got larger during the next four years but she suffered no pain or discomfort She was admitted to the Radcliffe Infirmary in February, 1918, and examined by the late Sir William Osler and the notes which he dictated while examining the patient I give in his actual words

A healthy woman, aged 41 not anæmic pulse regular, arteries good *On examining the abdomen there is a large* irregular prominence *in the* epigastric left hypochondriac and left lumbar regions, which lifts the costal margin and bulges the left flank, there is also a marked prominence just above and to the left *of the umbilicus* The tumour crosses the mid line and extends nearly to the right mammary *line* and descends with inspiration No intrinsic movements could be seen, there is *slight diffuse* pulsation and coils of intestine are visible at the *navel On* palpation the mass occupies upper left quadrant of the abdomen it is irregular *and extends to level of left anterior superior* iliac spine and passes under left costal margin, the finger can be placed between it and the costal margin It is soft and elastic in front, there is no edge to *be felt* it is harder on the right side Where it is more irregular it descends freely with inspiration and the fingers cannot be placed above it Behind with fingers in *the renal region, it can* be pushed forwards and grasped between the hands and pushed down The colon cannot be felt over it the upper limit of dullness is in the mid axillary line on the seventh rib It feels soft, elastic, and mobile and is probably a soft elastic cyst hydronephrotic in origin the renal region is definitely occupied by the mass The right kidney is quite palpable and is not enlarged

Examination of Urine —Acid *specific* gravity 1020 urea 2 per cent, no abnormal constituent *Cystoscopy* —Both ureters secreting ureters catheterised and normal urine collected from each

Operation —March 5th 1918 A long para *rectal incision* was made on the left side, the tumour proved to be a cyst of the spleen about the size of an association football The spleen, much elongated, lay *on the* outer or left side of the cyst, and the splenic pedicle was stretched out over the convex cyst wall There were numerous adhesions of the cyst to the left vault of the diaphragm these were clamped divided, and ligatured some of them *with a little* difficulty, the splenic pedicle was divided and ligatured and the spleen removed

There was no difficulty with the operation except *in the* ligature of some of the strong vascular adhesions to the diaphragm The patient *made* a good recovery was discharged from hospital on March 31st 1918, and is in good health at the present date

The pathological report by Dr A G Gibson was as follows

Specimen consists of a spleen with large cyst wall attached, there is moderate fibrosis of the splenic tissue, the cyst itself is full of blood clot undergoing *degeneration This* is probably an infarction cyst

This case is an example of the real difficulty that often faces one in making a diagnosis of an abdominal tumour The tumour was without doubt a cyst, and the diagnosis of hydronephrosis was justifiable until after cystoscopy and catheterisation of the ureters; even then a cystic tumour of renal origin could not be excluded A splenic cyst was considered but one was unable to feel *anywhere* the *crenated border* of the spleen Moynihan[1] divides splenic cysts into (*a*) serous cysts blood cysts, lymph cysts, (*b*) hydatids; (*c*) dermoids This was a blood cyst and it is suggested that it may have been due to *an* infarct, which *appears* to have originated at the end of the last pregnancy, as it was directly after the latter that the swelling was noticed

CASE 2 *Large Extra peritoneal Fibro myoma* —D S a married woman aged 49, had noticed that her abdomen had been increasing in size for *the last nine years in fact* ever since she gave birth to her last child She consulted her medical man because of large veins in her legs chiefly the left and at that time *it was thought that she was pregnant, for the past two years she had suffered from frequency of* micturition and difficulty of control On July 10th 1919, she was seen by me *at the Radcliffe Infirmary, Oxford* On examination there was a large firm abdominal tumour springing apparently from the pelvis and reaching up to the umbilicus *The surface of the tumour was firm* hard, and non elastic and there was slight lateral movement On vaginal examination the uterus could be felt pushed back *behind the tumour it appeared to be of normal size and* to be separate from the tumour

Operation —A mid line incision was made between the pubes and the umbilicus *and in doing* so the tumour was slightly cut into, the peritoneal cavity could not be opened until the incision had been carried well above the umbilicus The tumour was found to be extra peritoneal and to be filling up the abdominal cavity by pushing the peritoneum in *front of it, the peritoneum had been raised in front as high* as the umbilicus The uterus and all its appendages were identified, they were normal and had been pushed down into the pouch of Douglas by the tumour

The latter was hard encapsuled and firmly attached to the *apex* of the bladder some of *the muscular fibres of the* bladder being divided during the process of separation, there was a second point *of attachment* at the umbilicus Elsewhere the tumour shelled out readily but some of the invaginated peritoneum had to be removed with it The gap in the *peritoneum was closed* and the abdominal wall sutured The patient's recovery was uneventful The tumour measured 10 in in its long axis the pathological report described it *as a fibro myoma* undergoing colloid degeneration It may have originated from the apex of the bladder or the urachus seeing that the tumour was firmly *attached to the apex of the* bladder and the umbilicus, the two attachments of the urachus it is reasonable to assume that it *originated* in the latter structure

Thomson Walker[2] states that fibromyomata of the bladder may be intra vesical, interstitial, and extra-peritoneal, *and* that about 20 cases have been collected This case may then be regarded either as an extra peritoneal fibromyoma of the bladder, or a fibromyoma of the urachus

A CASE OF

PARALYSIS OF THE SOFT PALATE FOLLOWING NON DIPHTHERITIC TONSILLITIS

By J PEREIRA GRAY M D BRUX M R C S ENG

THE *following* case is of sufficient interest to merit permanent record

I W aged 10 consulted me on July 1st for a sore throat On examining the fauces the left tonsil was found patients with fever.—Experiments on the Regulation of the Blood's Alkalinity, by J. S. Haldane.[1]—The Action of Diuretics, by Arthur R. Cushny and C. G. Lambie. Diuretic drugs may act directly on the kidney itself, or indirectly through changes in the blood or in the circulation. Among the diuretics examined the increase in the urine appeared to depend directly on the blood flow through the kidney in only one instance—pituitary extract. Under caffeine the diuresis begins before the accelerated flow and lasts long after it has become normal. Its action is not dependent on changes in the blood, but on changes in the renal cells. The simplest view of the action of this drug is that it causes diuresis by reducing the resistance to filtration through the glomerular capsule by a specific action on its cells. The diuresis of salts and urea is not necessarily accompanied by acceleration of the blood flow, though this may accompany it in the beginning, and presumably favours its occurrence. Adrenalin lessens the blood supply and thus the secretion of urine, while section of the splanchnic nerve has the opposite effect in increasing the blood flow through the kidney and the amount of urine. Strophanthin had no diuretic action, nor did it alter the circulation through the kidney in moderate doses, while larger ones increased the blood pressure, slowed the renal blood flow, and lessened the secretion of urine. Rabbits anæsthetised with urethane 1·5 g. per kg. were employed.—The Coagulation of the Blood, Part II., The Clotting Complex, by H. W. C. Vines. According to this author, the inauguration of blood coagulation depends on the presence of a complex in which three substances are combined: a lipoid, calcium, and a protein. The lipoid and the calcium are essential. The calcium-lipoid combination does not yield calcium ions. The function of the protein is apparently secondary; it seems to render the lipoid compound more sensitive and may act by keeping the latter in a state of fine suspension. The compound described has properties resembling those of the thrombokinase of Morawitz rather than of the prothrombin of Howell.—The Effects of Respiration of Oxygen on Breathing and Circulation, by L. Dautrebande and J. S. Haldane. The authors sought to determine, by themselves breathing oxygen and air from two Douglas bags, whether there is any fall in alveolar CO_2 pressure when oxygen at increased partial pressure is breathed. They conclude that respiration of oxygen, particularly at increased barometric pressure, increases the breathing and diminishes the pulse-rate.—The Comparative Atrophy of the Skeletal Muscle after Cutting the Nerve and after Cutting the Tendon, by A. Lipschütz and A. Audova.

[1] Sir B Moynihan Abdominal Operations

[2] J W Thomson Walker Genito Urinary Surgery

British Journal of Ophthalmology. July–September, 1921.—In the July number Colonel R. H. Elliot discusses the yielding of the optic nerve-head in glaucoma. The lamina cribrosa is derived partly from the scleral tissue and partly from neuroglia. Its density and its exact distribution vary considerably. Moreover, the density of the lamellæ is by no means necessarily uniform in different parts of the nerve-head. These points have been elaborated by Fuchs of Vienna, and the present paper is mainly a comment on his work. Its practical bearing on the formation of the glaucoma cup is important and the anatomical findings go far to explain the variations from the typical glaucoma cup of the text-books which are so frequently found. Light is also thrown on the meaning of the various forms of paracentral scotoma which are found clinically.

In the August number W. H. McMullen and M. L. Hine record some cases of chronic progressive ophthalmoplegia externa developing during childhood. They say that no very sharp dividing-line can be drawn between these cases and congenital cases on the one hand and cases developing in later life on the other. "All may be due to an 'abiotrophy' or 'lack of inherent vitality' of the specialised cells of the cranial nerve nuclei involved, the time of onset depending on the degree of vitality with which these cells were originally endowed."

In July and August Basil Graves describes a new instrument for contact-illumination in the examination of the cornea and anterior part of the eye. In using the corneal loupe the detection of fine changes is often rendered difficult by the reflex of light from the corneal surface. The contact-illuminator gets rid of this difficulty. For examination of the cornea it is placed on the scleral margin so that the illumination is lateral. One of the claims made for the instrument is that it is an aid in the early diagnosis of glaucoma, revealing a slight corneal haze after the instillation of cocaine when the tension is in any degree raised—a haze to be distinguished from that of cocaine drying which, as is well known, attacks the corneal surface when the lids are allowed to remain open after a too liberal use of the drug.

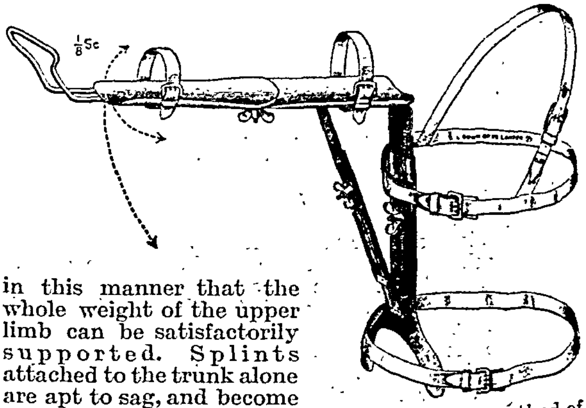
In August and September S. L. Ziegler discusses the Ocular Menace of Wood-alcohol Poisoning, on which we comment elsewhere.

The September number is largely taken up by an article by Priestley Smith on the Eye of the Ox and its Internal Blood-vessels. It is most beautifully illustrated by 46 figures from microphotographs of injected specimens taken by Mr. Frederick C. Lowe of Wednesbury.

New Inventions.

AN ADJUSTABLE ABDUCTION SPLINT FOR THE SHOULDER.

THIS splint is intended for use in all cases in which it is desired to abduct the shoulder-joint. Originally designed for use after dislocation, it has been found serviceable in paralysis of the deltoid from any cause, and after various injuries about the head and neck of the humerus, fractures included. The splint takes its "lift" off the pelvis, instead of off the soft tissues of the chest or abdominal wall, as it is only in this manner that the whole weight of the upper limb can be satisfactorily supported. Splints attached to the trunk alone are apt to sag, and become ineffectual. In standing at rest, the natural method of supporting the weight of the arm consists in placing the hand on the hip, and this is imitated by a small length of malleable metal, suitably curved, resting upon the iliac crest, and kept in position by a web band passing round the bony pelvis, at the same level as a truss-spring. The only other attachment consists in a Y-shaped band which passes above and below the opposite shoulder. The splint is adjustable for either arm; the range of abduction varies between half a right angle and a right angle and a half; the height can be adjusted; the elbow can be left free, or fixed at any desired angle by a butterfly nut; the wrist and hand are supported by a bar of copper wire which can be lengthened or shortened as required, and bent to any angle. Normally the splint is made of thin sheet-iron, and its weight is not irksome. For special cases, it is made of duralumin, a light but strong alloy of aluminium. Messrs. Down Bros. are the makers.



ALAN H. TODD, M.S., F.R.C.S., B.Sc.

of remedies for fever gives in different columns information as to name of drug, its composition, its formula, and dosage. In another table an attempt is made to classify the numerous preparations containing creosote and guaiacol; another table shows the reader what drugs to use for night sweats. Another table is an admirable summary of the various skin diseases due to the tubercle bacillus, showing the usual site, the appearance of the lesion, and giving hints as to the differential diagnosis; yet another gives much concentrated information as to the various tuberculins, serums, and other specific remedies. Lists are given of health resorts, showing the nature of their climates and the particular tuberculous conditions for which they are best suited. A further section of this work deals with first-aid to the over-treated consumptive, treatment for atropine and morphine poisoning, for example, being described. Much space is devoted to orthodox methods of examination and treatment, and no reader can fail to be impressed both by the wealth of information and the small compass within which it has been condensed. Here and there the author commits himself to such a sweeping generality as: "Atypical forms of phthisis invariably have an unfavourable prognosis." But, on the whole, his information is as truthful as it is full.

SEXUOLOGY.

A Young Girl's Diary. Translated from the German by EDEN and CEDAR PAUL. London: George Allen and Unwin, Ltd. 1921. Pp. 271. 12s. 6d.

THERE has recently been a change of attitude towards the discussion of sex matters, particularly in regard to venereal disease, concerning which men and women of dignity and position give support to propaganda which, a few years ago, would have been excluded from the pages of any newspaper. In this connexion the need for education of the adolescent is fully recognised; further, it is well known that withholding sex information from the child results in that information being acquired in fantastic form from unclean sources. Few people deny this, but custom is strong and there often exists between parent and child a barrier as strict as any taboo of primitive people.

"A Young Girl's Diary" (which we assume to be authentic, though the literary detective might find room for question) shows us what happens on the child's side of the barrier. The writer belonged to the pre-war upper middle class in Austria, and the diary presents an intimate record of school-girl doings and confidences; through it runs one theme—the pursuit of forbidden knowledge—accompanied by furtive speculation shared by school-mates, talks with crudely informed domestics, searches in encyclopædias, pride when some point is cleared up, fantastic ideas of married life and strange theories about venereal disease. If the power of taboo will allow us to admit that we also were the victims of the conspiracy of silence there is very little, except a "Peeping Tom" episode, that would not be acknowledged as having happened to many of us in childhood.

The diary shows how the barrier, originally erected by the parent, is carefully maintained by the child, who uses deceit and cunning to prevent intrusion by grown-ups into secrets shared only by chosen intimates. Many incidents described are of particular interest to students of child-life; to parents still guided by old custom the book will bring home what may be happening in the minds of their supposedly ignorant offspring. There is a danger, however, lest some people may judge that the taboo was in need of reinforcement and that the writer of the diary was an evil-minded girl who should have been punished for wanting to know.

The most thought-provoking thing in the book is a publisher's slip limiting its "study" to members of the educational, medical, and legal professions. It is not easy to understand why parents belonging to trades or other professions should not read it

Monographien zur Sexualwissenschaft. I. Band: *Sexual-Physiologie*. II. Band: *Sexual-Psychologie*. Von Dr. med. H. ROHLEDER, Sexualarzt in Leipzig. Hamburg: Paul Hartung. 1921. Pp. 104 and 100. M.12.50 each.

Onanie und Homosexualität. Second edition. By Dr. WILHELM STEKEL. Berlin and Vienna: Urban and Schwarzenberg. 1921. Pp. 528.

1 and 2. Dr. Rohleder, a sexuologist practising in Leipzig, gives in two manuals a good outline of the physiology and psychology of the human sexual life, showing himself sometimes an idealist, at others a materialist. Thus he believes in desire for offspring as a component of the sexual impulse, but follows Steinach's hormone theory of its source perhaps rather too readily. For while no contradiction of the striking animal experiments of this worker has been made, yet their application to human subjects, and his histological and pathological specimens, have lately been impugned by competent judges. The practitioner consulted on problems like sexual prematurity, sex-instruction, sterility and impotence, nymphomania, and so forth, will find here a safe and interesting guide. One must except, however, masturbation, as to which this sexuologist notoriously takes up an extreme attitude. According to the statistics he himself quotes, moderate masturbation in adolescence is very widespread; in fact, an English public school physician is mentioned as giving a percentage of 92. When, after this, onanism is styled a sexual disease worse than syphilis or gonorrhœa, to be combated as vigorously as they are, one is astonished at the tricks a clever man's mind can play him.

3. The mischief actually done by this barbarous attitude is impressively shown by Dr. Stekel, the leader of a section of the Freudian school, in his full and highly individual work. The large majority of medical men will be interested and convinced by his demonstration of the thesis that infinitely more harm has been done by preaching against masturbation than by the practice itself. The second and larger part of his book is a comprehensive psycho-analytic study of sexual inversion. On the larval forms of this abnormality much light is thrown; for instance, well-known phobias, as against syphilis or tubercle, are shown sometimes to symbolise dread of inversion in a bi-sexually disposed subject. Like every investigator of genuine vocation, the author is especially interested in ætiology, and here defends the psycho-genetic theory against the doctrine (of Steinach and Hirschfeld) of physically determined sexual intermediate forms. He does not deny the existence of these latter, though rating their significance lower than does his master Freud. It may be illogical to argue from therapeutics to ætiology, but nevertheless if inversion is claimed as the result of an avertable psychical maldevelopment, then one looks with interest to the success or otherwise of its psychical treatment. The benefits described are not striking, except in one case, specially mentioned as occurring in a race very susceptible to suggestion. This is in accord with the verdict of Hirschfeld, a clinician of unrivalled experience, who has for some time decried psycho-analytic cures of inversion.

Die Geschlechtskälte der Frau. Second edition. By Dr. WILHELM STEKEL. Vienna: Urban and Schwarzenberg. 1921. Pp. 400. M.90.

The Beloved Ego. By WILHELM STEKEL, M.D. Authorised translation by ROSALIE GABLER. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1921. Pp. 237. 6s. 6d.

1. MANY of us were once familiar with a text-book in which we read, concerning anomalies of sexual feeling: "The reserve which properly attends this subject prevents scientific investigation of it." Only by realising that the scientific approach to any subject necessitates a complete absence of 'reserve' can one become reconciled to Dr. Stekel's frank and sometimes brutally honest book, in which he devotes nearly 500 pages to the study of sexual frigidity in women. The wealth and significance of his material compel the

Some Toxæmias of Pregnancy.

Numerous theories have been advanced in explanation of the ætiology of the toxæmias of pregnancy, but none of them has as yet met with any general acceptance, and the problem must be regarded as still unsolved. The possibility of maternal intoxication by fœtal protein has attracted some investigators, and attempts, mainly unsuccessful, have been made to produce anaphylactic shock in the pregnant animal by injections of fœtal serum. Others have regarded damaged or infarcted areas of the placenta as the source of the toxin, and have drawn analogies with the action of poisonous products derived from degenerating muscular tissues, as seen in wound shock. Of possible toxic products of fœtal metabolism we have as yet no definite knowledge, nor do we know to what extent fœtal metabolism throws additional strain on the maternal excretory organs. That such additional strain is thrown upon certain maternal organs in pregnancy is suggested by the work of **Herring**, who found a marked increase in weight of the liver in pregnant rats, the kidneys, on the other hand, showing no hypertrophy. In the absence of any definite knowledge of the ætiology of the condition, no rational method of prevention is possible, and we can only hope that, by a study of the functional condition of the organs mainly affected in the toxæmias, we may be able to prevent danger to the mother. From a clinical standpoint, it is of the utmost importance to decide at what stage a pregnancy complicated by albuminuria, or other indications of toxæmia, should be terminated. Though recent advances in pathological chemistry have contributed greatly to our knowledge in many fields of medicine, they have not as yet aided us appreciably in our diagnosis or treatment of the toxæmias of pregnancy. The subject is reviewed by Dr. O. L. V. **de Wesselow** in the current issue of *Medical Science*, and modern work on acidosis, and on hepatic and renal function in eclampsia and albuminuria complicating pregnancy is summarised. The theory that the condition is caused, or at least accompanied, by an acidosis—a theory which originated with **Zweifel**, who believed that the causative factor was an over-production of lactic acid by the fœtus—has not been confirmed by later work. There does not appear to be any great reduction in the alkaline reserve of the maternal blood, as estimated by its combining power for CO_2. Though the liver lesions are so striking a post-mortem finding of the disease, we know of no definite alterations in the chemical composition of the blood or excreta which we can ascribe to failure of liver function, except the abnormal distribution of the urinary nitrogen. As is well known, the percentage of total nitrogen excreted as urea is frequently found to be much reduced in eclamptic cases, and this has been regarded as evidence of failure of the urea-forming mechanism of the liver.

The work of **Folin** and **Denis** suggests, however, that there is an efficient extra-hepatic urea-forming mechanism, and **Stadie** and **van Slyke** found in a case of acute yellow atrophy that, despite almost complete destruction of the liver parenchyma, a large proportion of urea was still formed. Chemical methods of estimating the functional capacity of the liver are at present so unsatisfactory that from a clinical point of view they may be disregarded. In testing renal efficiency we are on firmer ground, but here, too, the results in eclampsia have been disappointing. The marked accumulation of urea and other nitrogenous waste products, so frequently seen in acute and certain types of chronic nephritis, is absent in the toxæmias of pregnancy. The non-protein nitrogen and urea of the blood are frequently within normal limits. This absence of definite nitrogenous retention is indeed one of the most characteristic features of the disease, and serves to differentiate the true eclamptic from cases of uræmia due to chronic interstitial nephritis complicating pregnancy. The blood urea in the toxæmias of pregnancy is therefore of no value in prognosis. The urea-concentration test is probably more valuable in following the course and estimating the gravity of the condition, but the available data are at present scanty. The absence, until recently, of labour wards in our general hospitals, and the difficulty of keeping the healthy expectant mother under continuous observation probably account for the numerous gaps in our knowledge of the physiology of normal pregnancy and parturition. Even the relatively simple problem of the nitrogenous metabolism in pregnancy has attracted comparatively few investigators, nor have we much definite information as to the amount of protein necessary for the diet of the expectant mother. German experience, during the years of the war, suggests that the undernutrition of the population led to a marked fall in the incidence of eclampsia. Of the effects of the lowered standard of living on the weight of the infants at birth we have seen no statistics. It is to be hoped that the development of the antenatal clinic will lead to further study of the physiology of normal pregnancy.

Much may be hoped from the coöperation of physiologists and clinicians. Prof. V. J. **Harding**'s work on the subject of nausea and vomiting in pregnancy, recorded in The Lancet of August 13th, was the outcome of a suggestion made by a physiologist, Prof. V. H. **Mottram**, as a result of his observations on the mobilisation of fat during hunger, pregnancy, and early lactation in animals. Prof. **Mottram** found: (*a*) that a day's hunger was sufficient to double the amount of fat in the liver, (*b*) that a marked fatty infiltration of the liver accompanied pregnancy and early lactation, and (*c*) that this last was more marked in timid animals, or in those which had just left the dealer, than in normal and well-fed animals. It therefore occurred to him that the ketosis of nausea and vomiting in pregnancy was due to fat mobilisation, and that to stop this mobilisation a diet containing large amounts of carbohydrate was indicated, together with the removal, if possible, of any unpleasant emotional state which would result in a glycæmia or glycosuria with a concomitant mobilisation of fat. The work is a particularly good illustration of the value of the application of physiological thought to a medical problem, and there was no obvious practical application of the original research at the time that it was done. Further than this, the nausea and vomiting in the early months of pregnancy is so nearly a physiological phenomenon that many who suffer, suffer gladly, believing it to be a sign that their infant will be strong; and even when the discomfort is considerable they may be impatient of treatment, believing the vomiting to be a natural event. The fact, however, that the condition lends itself to a simple and efficient treatment will be a boon to many, and the good results obtained by Prof. **Harding**, and others who have followed his teaching, will encourage real scientific investigation of other conditions that are on the borderland of physiological and pathological states. It has been accepted by some observers that the vomiting of pregnancy is a neurosis, and this view has received some support from the fact that it is sometimes readily and immediately controlled by suggestion. Prof. **Mottram**'s observations also throw light on this aspect on the repopulation of France, in which he shows the existence of definite areas of low birth-rate whose influence spreads outwards like the growth of a cancer in all directions, opens up a promising field for sociological investigation. The biological line of approach suggested by Mr. Pell is also worthy of consideration, but it cannot be carried on independently of experimental research. And if we may be permitted one last word of advice it would be to refrain from a too unkind exposure of the want of expert knowledge in other workers in this most technical field. Even a member of the National Birth-rate Commission might hesitate to draw his statistical data from the columns of the daily press.

THE EUGENIC PROSPECT: NATIONAL AND RACIAL.

By C. W. SALEEBY, M.D., F.R.S. Edin., F.Z.S. London: T. Fisher Unwin, Ltd. 1921. Pp. 239. 12*s*. 6*d*.

Dr. Saleeby has paid another visit to America and has reinforced the inspiration and revelation of his previous visit. The result is a series of vigorous essays, written in his well-known popular style, on a large variety of topics ranging from the "decay of parenthood" to a eulogy of skyscrapers. He is greatly impressed, as indeed every liberal-minded visitor to the States must be, with the practical idealism of Americans. One could wish, however, that his stories of successful reforms were garnished with a few more of the practical details which so shrewd an observer must undoubtedly have gleaned. We are told, for example, that in Pittsburgh before the days of the Bureau of Smoke Regulation the pneumonia death-rate was the highest in the world. But we are not told how much the death-rate has been reduced nor what the minimum is to which smoke production has been reduced—only that it is now less smoky than Nottingham, which after all is a matter of judgment (not of soot records), and might even be considered a matter of opinion. The essays are thoroughly up to date, and while the reader may not always agree with the teaching, he must always admire the lucid and forceful manner with which it is presented.

JOURNALS.

Journal of Physiology. Edited by J. N. LANGLEY, D.Sc., LL.D., F.R.S. Vol. LV. 1921. Nos. 3 and 4. Cambridge University Press. Pp. 159–304. 12*s*.—The Regulation of the Reaction of the Blood, by C. Lovatt Evans.[1]—The Recovery Process of Excitable Tissues, Part II., by E. D. Adrian. By means of the capillary electrometer experiments were made to find out the relation between the decline of the electric response and the return of excitability in different tissues.—The Physiology of the Veins, by J. F. Donegan. The author's experiments were directed chiefly to comparing the effects of nerve stimulation on different veins and to determining the course and origin of the veno-motor nerves and the extent of central control and reflex effects. The methods used are described. The veins of the animals investigated (dog, cat, and rabbit) can be roughly divided into three groups. (*a*) The superficial veins returning blood from the skin. These receive sympathetic fibres. The veins of the hind limb receive them from the second to the fourth lumbar nerves inclusive and chiefly by way of the seventh lumbar and first sacral ganglia, those of the fore limb from the sixth to the eighth dorsal with cell stations mainly in the stellate ganglion. They react differently in different individuals, in some they contract on the first weak stimulation, in others they only contract after repeated stimulation. These veins were not found to react to the usual vascular reflexes, but probably they take part in temperature reflexes. (*b*) The mesenteric veins are also supplied with sympathetic nerve fibres which have their cell stations in the ganglia of the solar plexus and the inferior mesenteric ganglion. They are influenced reflexly in the same way as the arterioles. (*c*) As to the veins from muscles and the vena cava no effect was found in these. Adrenalin, 1 in 1,000,000, causes contraction in the veins of groups (*a*) and (*b*), but is practically inert in those of group (*c*).—The Survival of Motility in Mammalian Spermatozoa, by C. G. L. Wolf. This paper is the outcome of investigation in the School of Agriculture, Cambridge, and is one of great significance, bearing as it does on a problem of much practical importance in animal breeding—viz., the possibility of being able to keep spermatozoa viable for a sufficient length of time so that they may be transported and used for distant insemination. Up to now it appears that artificial insemination has been practised only with semen immediately after ejaculation, or at most, an hour or two after passage. The author investigated the conditions under which survival could best be prolonged. Wolf states that it is known that mammalian spermatozoa remain viable outside the male organism for periods up to 20 days, so that it ought to be quite possible by providing a suitable environment to keep them potent for some considerable length of time. The author's experiments were made on the epididymis of rabbits, to determine the effect of adding buffer salts to a solution of the Locke type. Experiments made to fecundate rabbits with spermatozoa which had been kept in salt and glucose solutions were unsuccessful, but it would appear that rabbits are very unsatisfactory animals for artificial insemination. It was found that the motility of rabbit spermatozoa can be preserved for at least nine days by placing the juice of the epididymis in a Tyrode solution which can be buffered and to which glucose has been added. Oxygen is passed in and a suitable amount of sodium bicarbonate added. The preparation must be kept at a temperature near the freezing point of water.—*Studies on Respiration and Circulation in the Cat. II.* The Effects of Hæmorrhage and Transfusion of Gum-saline Solution, by Y. Doi. When the blood pressure of a cat is lowered to various levels by progressive bleeding the amount of oxygen taken in by the animal and its minute volume of blood flow through the lungs decrease with a fall of blood pressure. The first fall of blood pressure from the normal height has greater effect on the minute volume per millimetre than the subsequent drop. When the blood pressure falls to a low level the decrease of the amount of oxygen taken in is less than that of the minute volume. The frequency of respiration and pulse-rate increase with a fall of blood pressure, and the volume of each respiration and of each heart-beat decrease with a fall of blood pressure. When the blood pressure is lowered by hæmorrhage injection of Ringer's solution or gum-saline solution raises it to normal height, and increases to normal values the amount of oxygen taken in and the minute volume. Gum-saline solution sustains these conditions for a longer time than does Ringer's fluid.—The Function of the Urinary Tubules in the Frog, by Mildred Atkinson, G. A. Clark, and J. A. Menzies. The authors conclude from experiments made by the perfusion method that urea, sodium sulphate, and glucose are filtered through the glomerular membranes, that the cells of the tubules are capable of transmitting urea and sodium sulphate, but not glucose, from perfusing fluid to urine, and that these results are not altered by the presence of 2 per cent. gum in the perfusing fluids, but the gum prevents the occurrence of œdema in the kidneys.—The Effect of Cooling Power of the Atmosphere on Body Metabolism, by J. A. Campbell, D. Hargood-Ash, and Leonard Hill. The technique is described and experiments are recorded showing the effects of out-of-door and indoor conditions upon metabolism. It is considered that basal metabolism of the body cells is raised by cool out-of-door conditions, and that shivering is not necessary to raise metabolism. The metabolism is controlled by cooling power, not by temperature. Formulæ are suggested for rapid calculation of heat production of the resting subject under comfortable indoor conditions and under cool out-of-door conditions. It is considered that the former may possibly afford important information regarding

Annotations.

"Ne quid nimis."

CARBON MONOXIDE IN COAL-GAS.

TWENTY years ago it was agreed that in view of the imperfect state of the gas fittings in the poorer houses of urban districts the only effective method of preventing danger from leakage was to fix a limit which the carbon monoxide should not exceed. After passage into law last year of the Gas Regulation Act, a departmental committee was appointed by the Board of Trade to consider whether it was necessary under present conditions to continue to enforce any such limitation. Sir William Pearce, M.P. (chairman), Dr. T. Carnwath, Mr. William Doig Gibb, and Mr. T. Gray, D.Sc., were the members of this committee, which has just brought in its report. Dr. J. S. Haldane in his evidence before the committee thought that in view of the improved forms of gas burners now constructed the maximum percentage of carbon monoxide in lighting gas for domestic use might be increased to 20 per cent. without undue risk. This would allow the admixture with coal-gas of one-third blue water-gas or one-half carburetted water-gas. The advocates for no limitation based their case on the advantages of cheap gas, especially for heating and cooking. The committee, after weighing carefully all the facts concerned, concluded, on the balance of advantage to the public, by recommending non-limitation. Increased risk from the poisonous nature of carbon monoxide was not, they thought, serious when all practicable precautions were adopted. The danger of increased death-rate was in any case of small dimensions and against this must be set the unquestionable improvement in the public health by the reduction of smoke and fog owing to increased use of gas. The economic advantages following the use of water-gas were proven and they were greatly impressed by the necessity of allowing the development of the gas industry to proceed without any check on its natural progress. The committee suggested, however, that the departments concerned should carefully watch the situation so that, should freedom from limitation be accompanied by unfavourable results, the attention of Parliament might again be directed to the matter. All the witnesses heard by the committee agreed that the distinctive odour of coal-gas is a necessary precaution, and the committee suggested that it should be made an offence to supply any gas for domestic purposes which does not possess the distinctive pungent smell of coal-gas.

The committee was assisted in coming to this decision by the experience of the Public Health Service of the U.S.A. communicated in a letter from Surg.-General H. S. Cumming to Dr. G. S. Buchanan. From this it may be seen that the composition of illuminating gas at Washington, D.C., described as a "straight water-gas," is as follows:—

	Per cent.		Per cent.
CO_2	4	CH_4	13·6
Illuminants ..	11	H	38·4
O	7	N	3·5
CO	28·7		

which may be taken as fairly representative of the average composition in the U.S.A. From their experience it would seem that the use of water-gas presents great economic advantages, and that the presence of anything up to 30 per cent. of carbon monoxide has not proved prejudicial to the public health. The poisonous character of illuminating gas is apparently well understood in America, and householders are prompt to remedy small leaks. In view of all the evidence in regard to carbon monoxide, it is not believed in America that any danger can result from leaks of gas so small as to be imperceptible to the sense of smell so long as an amount of illuminant adequate to give it a strong odour is added to gas. This last point is, of course, essential.

A MEDICAL PHYSIOLOGIST.

THE Society for Experimental Biology and Medicine has issued a Memorial Number for Samuel James Meltzer, M.D., its founder and first president in 1903. The number consists of addresses by various members of the Society setting forth the services of Meltzer to the Society itself and to the great part played by him in shaping and hastening the development of scientific work in the United States and more especially in New York which, a few years before, "as a scientific centre was pretty bleak and barren." Meltzer was born in Courland, Russia, on March 22nd, 1851, was educated at Königsberg, and then studied philosophy and medicine in Berlin between 1875 and 1882, where he came under the influence of the great masters of medicine and of physiology—Du Bois-Reymond, Virchow, Leyden, Frerichs, Traube, Helmholtz, Koch, and others. In Berlin he had the good fortune, while a student of medicine, to attract the notice of the late Prof. Hugo Kronecker, who at that time was assistant to Du Bois-Reymond, and they jointly in 1881 published a classic memoir on the "Process of Swallowing," giving an entirely new interpretation, now known as the Kronecker-Meltzer theory, of deglutition, which has since been generally accepted. The friendship begun in Berlin lasted throughout the life-time of both master and pupil. Meltzer was a distinguished promoter of the application of experimental methods to research in American medicine; he inspired fidelity to truth and stimulated achievement, more especially in younger men. He began practice in New York in 1883 but did not give up his physiological outlook, and he endeavoured throughout to bring his experimental facts to clinical application. With the foundation of the Rockefeller Institute he was chosen to direct the division of physiology and pharmacology, giving up practice at considerable financial sacrifice. His productivity was remarkable, extending to over 240 papers on physiology, pharmacology, pathology, and clinical medicine. His views on the part played by inhibition in the general activities of the body were much in advance of those of his earlier contemporaries. The border-land between medical science and medical practice was his special field of work, and he brought about a helpful and sympathetic understanding between the laboratory worker and the physician. It was he who called attention to the fact that reflex excitation of the inspiratory muscles is accompanied by reflex inhibition of the expiratory muscles, and vice versa, and he went on to suggest that a similar relationship must prevail in the case of all antagonistic muscles such as the extensors and flexors of the limbs. He thus led up to the convincing demonstration given ten years later under the term "reciprocal innervation" by Sherrington.

In Meltzer's later years he published several papers on the action of adrenalin upon the blood-vessels and pupillary muscles, showing that the temporary action of adrenalin upon the blood-vessels may be converted into more lasting effect in the blood-vessels of the ear if those blood-vessels are first denervated by section of the vasomotor fibres in the sympathetic and third cervical nerves. In the mammal, injection of small doses of adrenalin have no effect upon the size of the pupil, but if the superior cervical ganglion be excised, then after a time a moderate dose of this drug brings on a marked and long-lasting dilatation. Incidentally, Meltzer was led to use the pig's eye as a biological reagent for the detection of small concentrations of adrenalin. His last extensive series of researches dealt with anæsthetisation and artificial respiration through pharyngeal and intratracheal sufflation. Meltzer kept in touch with progress in almost all branches of experimental medicine, his sympathies being very broad. He represented the physiological type of physician and was one of the few earlier physicians—S. Weir Mitchell and W. T. Lusk were two others—in the United States whose practice was based upon physiological training, aptitude, and interest. Meltzer died on Nov. 7th, 1920, and his

Additional Benefit.

INSURANCE against ill health has long been second nature among the salaried classes and the principle is becoming familiar among the wage earners, for the first National Insurance Act is now just ten years old. Medical benefit has, indeed, been much criticised both by those who give and those who take, but there is ever less talk of abolishing it and more talk of extending and improving the general practitioner service. We may hopefully picture this extension and improvement as a continuous process without being sanguine enough to expect to see so-called medical benefit covering the whole range of additional services conveniently summed up in the Dawson report, at all events in the immediate future. The hospitals cannot do much, for they are bankrupt, or nearly so. The State has made a small and promising essay in the shape of regional medical officers, and is now obliged by the economy campaign to draw in again. Both heads of the stream *from which the funds for an extended service were to come having* dried up, the position would be desperate were it not for one blessed fact: that while the understanding on the part of the great industrial community of what health means has been growing, and the demand for its realisation has been becoming *more insistent*, the ability to provide it for themselves has arrived. No one who looks at the improved standard of food, of clothing, of comfort, and of pleasure among the great majority of the industrial population can doubt that they are in a position to secure the same standard *of health if they regard it as worth the* outlay. Mr. JOSEPH GRIFFITHS in his thoughtful contribution to the hospital problem which we print on p. 633 *states in so many words that the working classes* are now in a position to provide a hospital service the like of which the world has never seen.

Nor is this any vague and unpractical dream. A provident scheme embodying these additional benefits has already taken shape in Brighton and the neighbouring part of Sussex, and our readers *are* familiar with its *main features*[1] as also with the *further proposal* to adapt the scheme to the needs of the metropolis.[2] And during the last week-end the final step has been taken of bringing this National *Provident Scheme for Hospitals* and Additional Medical Services before a larger public. The experiment is to be launched on Nov. 1st at three London teaching *hospitals, apparently, for the first time in history*, working in conjunction with one another. From the point of view of the patient coming within the income *limits defined* in the schedule—£250 a year for an individual, £500 for a family—the scheme offers so many patent advantages that the secretariat at 77, Cambridge-terrace, Paddington may expect to be overwhelmed more by applications than by inquiries. Were it not for its credentials the leaflet reads more like a rosy company prospectus than a serious business proposition. But the signatories of the circular letter who *form the organising and executive com*mittee are actually in a position to announce a scheme to which the public can subscribe in the confidence that if miscalculations have occurred or if unforeseen circumstances should make the services more difficult to render the promises will still be faithfully carried out, and it will not be the subscriber who will have to bear the inconvenience, friction, or temporary loss that may result. Members of the executive committee have carried through enterprises even more complicated and momentous with success. An annual subscription of £1 or £2 a year, without preliminary medical examination, is a small premium to *insure an individual or a family against all expense* involved in consultations and special treatment of all kinds, to say nothing of home nursing. As there will be no entrance fee a subscriber who leaves London forfeits at most the *remainder of his current* year's subscription. Arrangements have been made with the Sussex Provident Scheme whereby members of the National Scheme may enjoy Sussex benefits should occasion *arise during a temporary sojourn* in the county, and this concession may be prophetic of a network of areas throughout the country, cooperating at least enough for a change of residence *to involve only a change of institutions and* consultants available.

Certain minor services will be specially valued. Since the dental surgeon in attendance upon a member may arrange for consultations at the dental department of any of the cooperating hospitals, it follows that the presence or degree of pyorrhœa which can often *only be ascertained by means of* X rays will be detected in doubtful cases, much ill health and perhaps some teeth being saved thereby. Queen's and *other visiting nurses will attend sub*scribers within the Metropolitan police area at the request of the medical attendant. Few of those eligible for membership have room for resident nurses, and economic *conditions have driven to* permanent work that surplus female whose real function in the community was just such emergency nursing. Appreciation of this boon must ultimately lead to a large increase in *the staff of non*resident *nursing* institutions. Last year there were only 1951 Queen's nurses spread over the Kingdom, and the total staff of district nurses available, say, for Paddington and Marylebone numbered 12, and for Chelsea, Pimlico and Belgravia only nine; but these figures take no account of overlapping, nor of the new class of patient who will now be attended. *A few points unexplained in the circular* have interest for the doctor. Individual consultations may apparently be arranged at any of the cooperating hospitals—the London, St. Thomas's, the Royal Free—but in the case of members living in the four-mile area unable to leave their beds, will the choice of the consultant be conditioned by distance, by convenience, or by the selection of the family practitioner? Presumably as in the Sussex scheme consultants outside hospital work will receive some but not full fees for their opinion, and an especially popular member of a staff might find himself overwhelmed with new work. Old students of the cooperating hospitals will doubtless be among the first to act as agents for the National Provident Scheme among their patients since they know and trust the staff of their alma mater. This alone should ensure the success of the scheme.

educational propaganda concerning venereal diseases,[2] and provision of free treatment; and notification and permanent segregation of cases of leprosy. Special attention was paid to the various West Indian tropical diseases, and to the necessity of research in that connexion. The main impression to be gathered from accounts of the Conference is that, given the necessary financial means, the medical profession, working with the sanitary engineer, and having sufficient intelligent lay support, can render the West Indies perfectly safe for the rearing of a healthy native-born white population.

THE ECONOMICAL STORAGE OF FOOD.

THE Food Investigation Board have now presented to the Committee of the Privy Council for Scientific and Industrial Research their report for 1920. As in previous years, the report is divided into sections, each section showing the work of a different committee of the Board, with a note appended naming the papers and reports published during the year, or in course of preparation, by the particular committee in question. In the introduction reference is made to the establishment, now nearly completed, of the Low Temperature Research Station at Cambridge, and to a long report upon the general theory of preservation of food by cold, prepared by Prof. Walter Stiles. During the year the Fish Preservation Committee have published an interim report upon the brine-freezing of fish; the Meat Committee have discontinued their work on the preservation of beef by cold pending completion of the Research Station, but have investigated the production of lactic acid in muscle and the cause of moulds occurring in cold stores. The Engineering Committee are now producing a report of investigations upon the flow of heat through walls and of the specific heat conductivity of various insulators. The Oils and Fats Committee have continued their studies of the unsaturated fatty acids and the constitution of artificial fats derived from the alcohol mannitol and from methyl glucoside. The Canned Foods Committee have completed a report on the effect of a diet of putrefying meat on the health of animals, and other reports on the chemistry and bacteriology of canned foods is in process. Of great interest is the work of the Fruit and Vegetables Committee, which falls into three main groups of investigations: (*a*) into preservation and physiology of living fruit after it is gathered; (*b*) into diseases of gathered fruit; and (*c*) into the chemistry of the ripening process, particularly the chemistry of pectin and the mechanism of destructive oxidation of tissues following injury to some fruits. Experiments are being conducted with two types of English apple in order to determine the best temperature and degree of humidity, the longest possible period, and the period most commercially profitable for storage, together with the effect upon the keeping properties of apples of the soil conditions to which the trees were subjected: various methods of packing are also being investigated, with the object of discovery of a method whereby the fruit may be packed once for all by the grower and only opened after sale; and an inquiry is proceeding into the comparative advantages of cold and "gas" storage. By the results so far obtained, a temperature of 1° C. with a humidity of 85 per cent. is shown to give the best preservative effects; clay soil is preferable to chalk for cultural conditions, and chalk to fen-land; wooden boxes are found more satisfactory for packing purposes than cardboard cases, and tissue paper wrapping of apples is desirable. The storage life of apples held in "gas" (concentration averaging 14 per cent. carbon dioxide and about 8 per cent. oxygen) was about twice as long as that of controls stored under ordinary conditions; a full report of the experiments will shortly be available. The investigation of the oxidising enzymes of fruit with special reference to discoloration has been completed, and it has been found that fruits can be placed in two classes. The first group is of fruits containing two enzymes, a peroxydase, an oxygenase, and a substance with the catechol grouping, and includes the apple, quince, pear, plum, cherry, peach, apricot, medlar, strawberry, banana, grape, fig, and mulberry; the second group is of fruits containing only a peroxydase, no oxygenase or catechol substance being detected, and includes the orange, lime, lemon, grape-fruit, raspberry, blackberry, red currant, black currant, gooseberry, pomegranate, pineapple, melon, and tomato. Copies of the report are obtainable at H.M. Stationery Office, Imperial House, Kingsway, W.C. 2. Price 1s.

WOOD-ALCOHOL POISONING.

A GOOD deal has been heard in America on wood-alcohol poisoning, more especially since the adoption of the prohibition policy. The acute toxic symptoms which may be rapidly fatal are generally accompanied by blindness, partial or complete, or blindness may ensue in a case where acute systemic symptoms have been wholly absent. In cases that survive partial recovery of sight is not uncommon. Ziegler[1] believes that the primary and fundamental lesion in all cases is a profound injury of the pituitary body. "The changing but steadily contracting fields, the fugitive scotomata, the visual loss and recovery, the sclerosed or atrophied nerve-heads, the fixed and dilated pupils, the temporary paresis of the extra-ocular muscles, the ptosis, the ataxic gait and the mental hebetude are all characteristic of pituitary involvement." He records six cases in most of which recovery of vision took place. It is to be noted, however, that these are not recent cases, but all date from before the era of prohibition. The treatment adopted included the administration of alkalies and negative galvanism applied directly to the eye. A point worth noting is that the end-product excreted by the kidneys is formic acid and that this reduces Fehling's solution, so that a wrong diagnosis of diabetes is quite possible.

THE TREATMENT OF GASTRIC ULCER.

FEW medical problems to-day are so much a matter of controversy as that of the treatment of gastric ulcer; the opinion of so experienced a physician as Dr. Frank Smithies, Professor of Medicine at the University of Illinois, and for many years gastro-enterologist to the Mayo Clinic, is therefore of especial interest. In a recent paper[2] Smithies calls attention to the paramount importance of basing treatment on modern physiological and pathological knowledge. It is clear at the outset that no treatment can hope to give a high standard of results which neglects to deal with the primary focus of infection which lies at the root of the disease; and physicians often complain that surgeons tend too readily to perform drastic operations without at the same time seeking to eliminate readily accessible sources of infection. In deciding the criteria for surgical treatment Smithies states that, "unless ulcers with much scar, or causing great gastric deformity, are demonstrated to be luetic, little hope of permanent relief by medical measures can be offered"; extent, chronicity, and the tendency to hæmorrhage are the factors on which he lays stress as determining the advisability of surgical interference. In a disease requiring such prolonged medical treatment as must a chronic gastric ulcer, we are faced with the paradox of surgery being the more economical treatment. Having selected the cases, more recent and less extensive, suitable for medical treatment Smithies lays particular emphasis on the importance of securing true physioof the question, and it is to be remembered in this connexion that many activities that result from a physical process of excitation can be arrested by suggestion. There is, for instance, the well-known fact that the sneeze which ordinarily follows the sniffing of pepper up the nostril can be inhibited against the patient's will, by contra-suggestion. If Prof. HARDING'S important work stands the test of time it may point to a more rational explanation of some conditions that are at present apt to be dismissed as neuroses.

Medical Education and the Rockefeller Foundation.

IN a review of the work done in 1920 by the Rockefeller Foundation, its president, Mr. GEORGE E. VINCENT, surveys achievements truly called world-wide. This review, taken along with the appended programme for 1921, shows that the minds directing the activities of the Foundation are sensitive to the change of attitude as to the scope of medicine which is gradually gaining ground in civilised countries. Public interest, while increasingly concentrated on the science of disease, is shifting towards its application to the prevention of ill-health. The doctor is now being called upon to keep his clients well, and while no part of his old training may safely be omitted, the new outlook adds greatly to his present responsibilities. The consequences for the training schools are fundamental. Recognising that modern medical education can no longer be maintained on a commercial basis, the trustees of the Foundation take the view that it is an essential social task for which private or Government aid must be provided. In no more fundamental way could the Foundation have contributed to progress than by helping strategically placed medical schools in various parts of the world to increase their resources and to improve their teaching and research. Seeking to fulfil its chartered purpose to promote the well-being of mankind throughout the world, the Foundation, among other good works during 1920, aided six medical schools in Canada; gave a large sum—eventually to be 5,000,000 dollars—to University College, London, for building and endowment; appropriated a million francs for the Queen Elisabeth Foundation for Medical Research in Belgium; agreed to contribute towards the complete rebuilding of the medical school of the University of Brussels; continued to construct and to maintain in Pekin a modern medical school with a pre-medical department; besides helping 31 hospitals in China to increase their efficiency. Moreover, it gave support to the School of Hygiene and Public Health of the Johns Hopkins University, continued to contribute towards a campaign against yellow fever in South and Central America, and gave financial and scientific aid to the prophylaxis of malaria and hookworm disease, as well as to many other medical enterprises—the whole involving an expenditure of over thirteen million dollars.

The campaigns against yellow fever and malaria are described in some detail. Once the scientific basis of malaria control is well established in any district there is ample opportunity for experiments testing various practical measures under different conditions. Apart from other well-known methods of preventing the deposition of the eggs and growth of the larvæ of the anopheles mosquito and of their destruction, in certain regions where water is abundant resort was had to "policing" the water by fish, as it was found that if the streams are dammed to form lakes the "top minnows" prove an effective ally. Each minnow consumes about 165 large mosquito larvæ a day, and appears to eat the mosquito eggs as fast as they are laid. A still more novel method was adopted in Louisiana, where the grasses on the banks of the stream form a protected zone in which eggs may be deposited beyond the reach of the top minnows. In order to clear away these grasses the strips along the "bayou" or sluggish stream are turned into pasture land on which cattle are allowed to feed. The cow crops the grass close along the low banks, and leaves the larvæ a prey to the eager minnows, the appetites of minnow and cow working together for the protection of man. To all these experiments, to medical science and practice in general, and especially to educational institutions, the Rockefeller Foundation plays the part of fairy godmother, giving due encouragement to such immediate schemes of public health as may be called paying concerns, but reserving her best gifts for the higher education of the doctor, in which lies the chief help for the future. It is the wide and comprehensive outlook on the medical problems of the world, even more than the immense sums at its disposal, which makes the Rockefeller Foundation an international potentate.

◆

The Health Committee of the League of Nations.

THE Health Committee of the League of Nations has just held its first meeting at Geneva, and has submitted to the Council its recommendations for a new health organisation. The members of the committee are as follows:—

Dr. Léon Bernard, professor of hygiene in the University of Paris; Dr. G. S. Buchanan, senior medical officer of the British Ministry of Health; Prof. A. Calmette, director of the Pasteur Institute in Paris; Dr. Carozzi, medical director of the International Labour Bureau; Dr. Henri Carrière, director-general of the Swiss Public Health Service; Sir Havelock Charles, president of the Medical Board for India; Dr. Chodzko, Minister of Health for Poland; Dr. Lutrario, director-general of the Italian Public Health Service; Dr. Th. Madsen, director of the State Institute of Serotherapy at Copenhagen; Prof. Miyajima, of the Kitasato Institute for Infectious Diseases, Tokio; Dr. Pulido, president of the Spanish Royal Council of Public Health; Mr. O. Velghe, director-general of the Belgian Public Health Service; Prof. C.-E. A. Winslow, director of the League of Red Cross Societies.

Although elected on their personal qualifications, the committee will be seen to be nationally as well as professionally representative. Ten of the members already belong to the Committee of the Office Internationale d'Hygiène Publique. The acting medical secretary, Dr. E. J. Steegmann, of the British Ministry of Health, is retiring after two years' work of preparation in favour of Dr. Rajchman, of Warsaw, who has been appointed permanent medical director.

BRITISH ORTHOPÆDIC ASSOCIATION.—A meeting of this association will be held on Sept. 24th and 25th at the Shropshire Orthopædic Hospital, Oswestry. On Sept. 24th, at 9.30 A.M., executive proceedings of the Association will take place, and at 10 A.M. visitors will be shown round the hospital by the staff. Sir Robert Jones will conduct an out-patient clinic. Mr. Naughton Dunn will give a demonstration of treatment of calcaneo-cavus with cases, casts, and X rays. Mr. D. McC. Aitken will demonstrate plaster work. Mr. G. R. Girdlestone will speak on bone-grafting for tuberculosis of the spine in children, showing cases. In the afternoon visits will be paid to after-care centres in Shrewsbury, Oswestry, and Wellington. On Sept. 25th, at 10.30 A.M., operations, as cases permit, will be performed by Sir Robert Jones, Mr. Girdlestone, Mr. Aitken, and Mr. Dunn.

syphilis of the lung. The pulmonary symptoms in these cases are either coincident with early syphilis or constitutional syphilis of other viscera in which prompt improvement or even complete disappearance of signs and symptoms results under anti-syphilitic treatment. According to the writers, clinical pulmonary syphilis may occur (1) as isolated gummas of the lung, (2) as diffuse syphilitic fibrosis, and (3) possibly as a diffuse broncho-pneumonia. Of these, gumma of the lung, though generally regarded both clinically and pathologically as extremely rare, is not so very uncommon as the initial stage of fibrosis followed by cavitation. The clinical picture depends entirely on the situation of the process and the stage of its development. Diffuse fibrosis or chronic interstitial pneumonia is the commonest form of syphilitic lung disease. The fibrosis in and about the bronchi gives rise to dyspnœa, coughing, and vascular changes leading to hæmoptysis. The occurrence of syphilitic broncho-pneumonia, which has been disputed by some authorities, is accepted by the present writers, as well as by Neumann, Fowler and Godlee, Fournier, Dieulafoy, Aufrecht, and others. The prognosis of syphilis of the lung may be said to vary with the time at which a correct diagnosis is established. In gummas and in the early stage of the fibroid type prompt institution of specific treatment renders the prognosis favourable, whereas the association of tuberculosis considerably aggravates the prognosis.

WE regret to announce the death, on Sept. 9th, of Sir Peter Freyer.

FACULTÉ DE MÉDECINE DE PARIS.—Special courses at the Clinique de Dermatologie et Syphiligraphie, Hôpital Saint-Louis, will be instituted during the autumn under the direction of Prof. Ed. Jeanselme. It is intended in future to hold two series of courses every year, one in October, November, and December, and the other in April, May, and June. Each series will comprise a complete course of dermatology and a complete course of venerology. The fee will be Fr. 150 for each course; the latter will begin each year on the second Monday in October and on the second Monday in April, at the Musée of the Hôpital Saint-Louis and at the amphitheatre of the clinic (Salle Henri IV.). Lectures and demonstrations will be held every afternoon from 1.30 till 4 P.M., the mornings being reserved for work at the Polyclinic, ward-visiting, out-patient consultations, &c. A certificate will be issued at the termination of a course. Those taking the course will register at the Secretariat de la Faculté de Médecine, Rue de l'École de Médecine (guichet 3). For all further information apply to Mr. Marcel Bloch, Chef de la Laboratoire à la Faculté, 40, Rue Bichat, Hôpital Saint-Louis, Paris 10e.

THE LONDON TOLL EXCHANGE.—The London Toll Exchange is now approaching completion and telephone subscribers should soon be able to make trunk calls extending over short distances with less delay than hitherto. Under the new system a subscriber wishing to call any provincial town within a distance of approximately 25 miles radially from the centre of London will ask for "Toll," instead of "Trunks." He will be connected to the London Toll Exchange, where the telephonist who answers him, besides recording particulars of the number, will herself establish the connexion to the desired subscriber. The General Post Office has issued a circular stating that the majority of such calls will be completed whilst the caller waits on the line, as in the local service. When a call cannot be connected on demand, owing to the lines being engaged, a subscriber's application will be booked and completed as soon as the telephonist is able to find a free line, when the subscriber will be rung up as in the case of a trunk call. At the date of opening the existing lines will be increased by 20 per cent., and the lines provided on the more important routes should be sufficient under present conditions for the immediate disposal of all traffic. The more important towns which will come within the operations of the London Toll service are: Ascot, Aylesbury, Bishop's Stortford, Buckingham, Dorking, Egham, Gerrard's Cross, Hatfield, Hertford, High Wycombe, Leatherhead, Luton, Maidenhead, Potter's Bar, Rickmansworth, St. Albans, Sevenoaks, Slough, Staines, Tring, Uxbridge, Walton-on-Thames, Watford, Weybridge, Windsor, and Woking.

ON THE
ORGANISATION OF A FRACTURE SERVICE.

BY HARRY PLATT, M.D., M.S. LOND., F.R.C.S. ENG.,
HONORARY SURGEON AND SURGEON IN CHARGE, ORTHOPÆDIC SERVICE, ANCOATS HOSPITAL, MANCHESTER; CONSULTING SURGEON, GRANGETHORPE HOSPITAL (MINISTRY OF PENSIONS), MANCHESTER.

SCHEMES for the efficient treatment of fractures have exercised the minds of surgeons for many years. War experiences have stimulated anew our surgical conscience in regard to this particular field of surgery, and it is now almost universally realised that in hospital practice the segregation of fractures in a special service or sub-service is an absolute necessity. Granted the fundamental principle of segregation, the actual details which go to make up an efficient scheme will tend to vary within wide limits according to local conditions. The scheme initiated by the writer at the Ancoats Hospital, Manchester, just before the war may be of some interest to surgeons in general, and to orthopædic surgeons in particular. The interruption of the war prevented the full development of the scheme, which has gradually assumed maturity during the past two years.

The Ancoats Hospital is a general hospital situated in a densely populated area, the majority of the inhabitants of this region being employed in some of the most important industrial organisations of the city. A considerable number of patients suffering from industrial accidents seek treatment at the hospital, and amongst these is found a steady flow of fractures; in addition, the hospital is called upon to deal with fractures occurring in individuals of all ages, not necessarily sustained in the course of employment. The surgical side of the hospital, to which 75 beds only are allotted, is divided into three services of equal size; one service, under the charge of the writer, is devoted exclusively to "orthopædic" surgery in its widest sense. The total accommodation for surgical in-patients is, however, not commensurate with the size of the out-patient clinics. Thus the orthopædic service alone has at all times a list of over 100 patients awaiting admission for operation. The number of fractures which can be admitted to the wards is therefore somewhat limited. But an average of 30 new fractures are dealt with each week as out-patients. All the fractures attending the hospital are treated in the orthopædic service. Patients reporting at the hospital for the first time are seen in the casualty department. Fractures of the lower extremity are admitted at once, if beds are available in the emergency wards, with certain exceptions—viz., the majority of fractures of the femur or of the bones of the lower leg in young children. Even in adults a certain number of simple fractures of the tibia and fibula are occasionally dealt with as out-patients, the Thomas splint being used as a routine. Upper limb fractures (simple) are temporarily splinted and referred for immediate radiographic examination. After receiving such first aid these patients are instructed to attend the special fracture clinic, which is held once weekly. The special fracture clinic is one of the three, weekly, out-patient clinics representing the out-patient department of the orthopædic service. The accommodation of the hospital at the moment precludes more frequent conduction of this clinic. In actual practice, however, it has been found that, having regard to the number of fractures attending the hospital, the one clinic a week is quite sufficient. Where for any reason a particular patient requires special supervision in the interval between the regular attendances, he is seen in one of the general orthopædic clinics.

The Fracture Clinic.

(*a*) *Surgical Staff.*—The clinic is under the immediate supervision of the senior surgical assistant of the memory will be a continuing inspiration, not only to members of the Society for Experimental Biology, but to all those who are now endeavouring to link up medicine more closely with physiology

---

MOUNTAIN SICKNESS

INTEREST in mountain sickness has been recently stimulated by the discussions in the press regarding the expedition which is to attempt to reach the summit of Mount Everest, the highest peak of the Himalaya Range It is a well known fact that travellers ascending to high altitudes suffer from a series of symptoms, varying in different individuals, but generally comprising shortness of breath, palpitation, prostration, and a disinclination for exertion, at still greater heights the symptoms may be more severe, and may include loss of appetite, nausea or vomiting, cramps, drowsiness giddiness, a throbbing headache, loss of mental power, and great bodily exhaustion, occasionally there are hæmorrhages from the nose, eyes, or mouth All these symptoms are aggravated if the ascent be made in stormy weather, or when the air is saturated with moisture The causes of mountain sickness have been variously attributed to diminished barometric pressure, deprivation of oxygen, heart failure or undue fatigue A combination of these causes may operate at times but most authorities are now agreed that the chief of these causes is deprivation of oxygen

Considerable light has lately been thrown upon the subject by Captain R W G Hingston, I M S, who, while attached to an expedition despatched by the Survey of India to the Western Himalayas and the Pamir Plateau, made a series of careful and detailed observations, the results of which he has published in the last issued number of the *Indian Journal of Medical Research* (Vol IX No 1) under the title of "Physiological Changes at High Altitudes and their Relation to Mountain Sickness " This malady affects people in different ways and at different altitudes, but a person ascending from a low altitude to a high one can become acclimatised to the requirements of the greater height Nature comes to the rescue by developing an increased number of red corpuscles to provide the body with additional oxygen carriers to meet the altered circumstances of the rarefied air Mountain sickness, therefore, is associated with an insufficiency in the number of red blood corpuscles which are necessary at higher altitudes to convey oxygen to the tissues When the ascent is slow and gradual there is a rapid manufacture of the corpuscles At sea level an ordinary person has in round numbers about 5 millions of these corpuscles in every cubic millimetre of his blood, and this number is sufficient to deal with the available oxygen, which at that level is about one fifth of the air breathed When, however the traveller ascends to 7000 feet, the barometric pressure is reduced by about one quarter, and the oxygen available is only three quarters of the amount that was available at sea level When a height of 18,500 feet is reached, the available oxygen is halved, and it is calculated by Captain Hingston that anyone arriving at the top of Mount Everest, which is 29 000 feet high, would only have at his disposal a third of the oxygen to which he had been accustomed at sea level Continued examinations of his own blood and that of other members of the expedition showed that when a man by slow and gradual ascent attained an altitude of 8000 feet, his red blood corpuscles had rapidly multiplied from about 5 millions to 6 and that when a height of 13,000 feet had been reached the number of these corpuscles had risen further to 7½ millions An ascent to 18,203 feet, the highest point attained, and a residence there for about two days showed that in his own blood the red corpuscles had increased to 8,320 000

The facts observed by Captain Hingston confirm the observation, well known in lesser degree in the European Alps, that an ascent from a low to a high altitude is associated with a definite and continuous change in the constitution of the blood, the result of the stimulus which rarefied air exerts on the blood forming mechanism of the human body By this means the individual can adapt himself to the higher levels if the ascent be made slowly and gradually, thus allowing the production of a sufficient number of oxygen carrying corpuscles This manufacture of red corpuscles is by no means slow, for instance, in one observation a short stay of two days at an altitude of 13,000 feet showed an increase of about 725 000 in the number of these corpuscles per cubic millimetre of the blood It is possible that there may be a limit to this power of the body to compensate for great altitudes, but it will be noted that the process was in active operation in Captain Hingston's case at a height of 18 200 feet above sea level The blood of the natives of the Pamir Plateau, habitually living at an average height of 13,500 feet, was carefully examined, and it was found that the number of red corpuscles in the blood of the average adult native was 7,590 000 per cubic millimetre, as compared with 7,102,000 in Captain Hingston's own blood at that level It is further of interest to learn that during descent from high to low altitudes, when the stimulus of the rarefied air was withdrawn, there was a gradual reduction in the number of the red corpuscles, though the rate of decrease was not so rapid as the rate of increase had been during the ascent After a short residence at sea level the number of red corpuscles had fallen to normal—namely, a little under 5 millions These observations supply an illustration of the wonderful power of the human body to adjust itself to changes in its environment, and that man may become acclimatised to an atmosphere containing only a half of the oxygen supply to which he has been accustomed Finally, Captain Hingston expresses the belief that individuals might with care gradually adapt themselves to a region where as at the summit of Mount Everest, they would find only one third of the oxygen which is available at sea level

THE WEST INDIAN MEDICAL CONFERENCE

THE recent West Indian Medical Conference at Georgetown was the seventeenth of its kind [1] and the first to be held in British Guiana The acting Governor, the Hon C Clementi stated in the course of his inaugural speech that the declining population of the colony, as contrasted with the increasing populations of Trinidad, Jamaica and Barbados, was due to climatic and sanitary conditions which are sufficiently explained when it is realised that the only area now colonised in British Guiana is a partially reclaimed swamp, four feet below high spring tides" Representatives of the London School of Tropical Medicine were present at the Conference having gone to the colony to investigate the causes of filariasis The deliberations lasted a fortnight, papers with a wide range of subjects being read and discussed The formation of a West Indian medical school was strongly advocated, and other topics of discussion were the possibility of a central medical service the safeguarding of the health of the immigrant population, the status and training of nurses infant welfare work, and the advisability of the appointment of a sanitary commissioner, free from local control, who might form a link between the various colonies concerned, the Colonial Office, and the London School of Tropical Medicine The resolutions passed by the Conference and forwarded to the acting Governor also included references to the following points Provision of pure water supply, efficient drainage, control of mosquitoes, and stringent enforcement of public health regulations, introduction of a suitable proportion of meat into the diet of the labouring classes hitherto almost exclusively vegetarian, control of midwives, registration of still births, and confidential notification of miscarriages and abortions; adoption of routine school medical inspection,

NATIONAL PROVIDENT SCHEME FOR HOSPITAL AND ADDITIONAL MEDICAL SERVICES.

THE LONDON SCHEME.

THE organising and executive committee of the National Provident Scheme, which consists of Sir Arthur Stanley, Lord Dawson of Penn, Sir Alan G. Anderson, Mr. W. McAdam Eccles, F.R.C.S., and Dr. J. F. Gordon Dill (Hon. Secretary), has issued an explanatory leaflet giving full particulars of the Scheme as applied to London.

The Problem.—The great and increasing cost and complexity of medical services beyond the attendance of a general practitioner have made it impossible for a large majority of the population to obtain full advantage of the progress of medicine, although it is obvious that many cases cannot be properly dealt with unless the doctor in charge has all modern facilities at his disposal. It therefore becomes a choice of either having to do without them or of accepting them wholly or in part as charity. Further, the voluntary hospitals are already obliged to charge for their services, and have to ask all their patients to contribute, as far as they are able according to their means, to the outgoing cost of their maintenance and treatment.

Hospital Coöperation.—But it has now been made possible, by the help and coöperation of the following hospitals, to meet these difficulties by the establishment of a Provident Scheme which will supply its members, *free of cost* (beyond their subscriptions as members), with practically all the highest resources of medicine which are available—viz., the London Hospital, St. Thomas's Hospital, and the Royal Free Hospital.

Scope of Scheme.—The Provident Scheme, it is explained, (1) has nothing whatever to do with the National Health Insurance or any other organisation for medical benefit; and (2) does not provide its members with ordinary medical (i.e., general practitioner) attendance, or other benefit to which they are entitled from the State or from local authorities, or under the National Health Insurance Acts; but (3) is for the benefit of those who, irrespective of class or occupation, are in a financial position which makes them eligible for election as members.

No preliminary medical examination is required before the admission of an applicant for membership.

Facilities Provided by the Scheme.

Except where otherwise stated, members will receive, *without charge* beyond their subscriptions to the Scheme, the following advantages:—

Consultations.—The medical attendant of a member may arrange, by appointment, for individual consultations at any of the coöperating hospitals, and such treatment as he and the consultant may jointly think advisable will be undertaken (at the hospital if this should be necessary).

For those members who are unable to leave their beds and who reside within a radius of 4 miles of Charing Cross, the services of visiting consultants may be secured by appointment. For members outside this area, but within the Metropolitan Police area, who are unable to leave their beds, free consultation may be obtained by appointment, subject to the payment to the consultant at the time of consultations of a charge of 10*s.* 6*d.* per mile (i.e., equal to one-half of the usual mileage rates) beyond the 4-mile radius.

Nursing.—The services of the "Queen's" and other visiting nurses will be available within the boundaries of the City and the Metropolitan Police areas for members at their own homes at the request of their medical attendants.

Dental Services.—(*a*) Treatment in hospital: Such dental treatment as may be considered necessary for a member whilst under medical or surgical care in a coöperating hospital. (*b*) Consultations: The dental surgeon in attendance upon a member may arrange by appointment for consultations at the dental departments of any of the coöperating hospitals.

Laboratory.—All the resources of the pathological laboratories of the coöperating hospitals will be available for the benefit of members after consultation, including bacteriological and pathological investigations and examinations beyond the province of general practice, Wassermann and Widal tests, &c., blood examinations and counts, the preparation of autogenous vaccines, &c.

X Rays.—Examinations (including opaque meals) will be available where found necessary after consultation, and a report will be supplied to the medical attendant of a member. Treatment by X rays will be given when, after consultation, it has been considered advisable.

Massage will be provided by appointment for members in whose cases it is prescribed after consultation.

Electrical Treatment.—i.e., galvanism, faradism, high-frequency, ionisation diathermy, &c. will be administered by appointment, after consultation, in suitable cases.

Hospital Treatment.—Urgent cases will be admitted to hospitals, as at present; other cases requiring operation or other hospital treatment will, after consultation, be admitted to hospital in due course, but a member will not take precedence over more urgent cases, and the ordinary hospital routine will not be disturbed. Members of the Scheme conforming to the rules will not be subjected to any almoner's inquiry or to any charge at the hospital.

Radium Treatment.—If, as the result of a consultation, it is decided that treatment by radium is necessary in the case of a member such treatment will be provided by arrangement with the Radium Institute.

Ambulances.—Will be available at the request of the medical attendant or of the secretary of a coöperating hospital for the transport of "stretcher cases" within the boundaries of the City and the Metropolitan Police areas.

Income Limit.

Persons insured under the National Health Insurance Acts are eligible for election as members of the Scheme without regard to income; but, in the case of all persons not so insured, limits of income to qualify for admission to membership of the scheme have been set out as follows:—

Group.	Description.	Limit of income of persons applying for membership (not insured under the National Health Insurance Acts).	Annual subscription.
I.—(*a*)	Single person over 16 years of age.	£250	£1 0 0
(*b*)	Widow or widower without children under 16 years of age or other dependents.		
II.—(*a*)	Married couples without children under 16 years of age.	£400*	£1 10 0
(*b*)	Single person with one dependent.		
(*c*)	Widow or widower with one child under 16 years of age or with one dependent.		
III.—(*a*)	Married couples with a child or children under 16 years of age or other dependents.	£500*	£2 10 0
(*b*)	Single person with more than one dependent.		
(*c*)	Widow or widower with more than one child under 16 years of age, or other dependents.		

For the purposes of the rules a person will be deemed to be a dependent who satisfies the Committee of Reference that he or she is living with and is wholly dependent upon the applicant for his or her support.

* In Groups II. and III. the above income limits have reference to the combined income of the persons in respect of whom application is made, and will be reducible as and when children pass beyond the age of 16 years or when dependency in the case of another member of the family ceases. Transfers from one group to another will otherwise be also rendered necessary from time to time, but (except in the case of children attaining the age of 16 years whose membership automatically lapses on the date of the sixteenth birthday) adjustments will only take place as from the expiration of any membership year.

logical rest for the stomach; every student knows that rest in bed will save a damaged heart muscle from many thousands of contractions per diem, but few yet visualise the effect on a recent ulcer which must be produced by the 2000 peristaltic waves which accompany a normal meal. To secure such rest complete fasting with rectal feeding for a period of five days or more is advocated, with direct duodenal feeding by a tube as an alternative; when food by mouth is begun, liquid carbohydrate mixtures given frequently in small amounts are those which will provoke the minimum of gastric response. For treatment with drugs Smithies has little to say; many will disagree with his condemnation of alkalies, though most clinicians are now in accord in deprecating the use of sodium bicarbonate. It is interesting to observe that when discussing surgical treatment Smithies advocates pyloric closure in all cases operated upon; it is perhaps the multiplicity of surgical procedures adopted that makes judgment of results so difficult. In an important article on jejunal and gastro-jejunal ulcer, Hurst and Rowlands,[2] suggest that, "If gastro-jejunostomy were only performed when there is a visible ulcer or stenosis of the pylorus or duodenum; if before the operation every possible source of infection in the mouth and pharynx were removed; if at the operation any associated disease of the appendix or gall-bladder were dealt with; if after the operation the patient were given adequate instructions with regard to diet and told to take additional feeds between meals; if moderation in smoking and the taking of olive oil before meals and alkalies after were also enjoined; then the chances that a gastro-jejunal or jejunal ulcer might develop would be reduced to a minimum." Confirmation of these opinions is given by the experimental work[3] of Goto, of the Imperial University, Fukuoka, Japan; this worker, in an extensive series of experiments on dogs, has shown the readiness with which, apart from operative trauma, peptic ulcer may be produced in the intestine when septic foci are present and a highly acid gastic juice is left unneutralised.

FIMBRIAL CYSTS.

ACCORDING to Dr. Henry Cohen,[1] of New York city, who records two illustrative cases, fimbrial cysts which have previously been described as parovarian cysts are of very infrequent occurrence. Of 269 cases of ovarian cysts studied by Wiener only ten were examples of this kind. The most frequent complication is torsion, which may lead to gangrene. In five of Wiener's cases there was free fluid in the abdomen, but in none was there a severe peritonitis. Rupture, hæmorrhage, infection, and malignant degeneration were some of the other complications. Pregnancy was present in 11 cases. It is therefore obvious that a fimbrial cyst with torsion and gangrene and free fluid in the peritoneal cavity associated with pregnancy, of which one of Dr. Cohen's cases is an example, is an extremely rare occurrence, and no similar instance could be found in spite of a careful search through the literature. The relationship of these cysts to co-existing pregnancy is of interest both from a mechanical and physiological standpoint. Owing to the menace to life of both mother and child, fimbrial cysts, like ovarian cysts, should be removed as soon as the diagnosis is made. Numerous cases have been recorded to show that pregnancy may go on uninterrupted even when an operation on the ovary takes place before the fourth month. Nine of Wiener's cases were operated on before the sixth month with only one abortion, which occurred 11 days after a salpingo-oöphorectomy. In Dr. Cohen's second case, which occurred in a married woman, aged 23, the clinical picture simulated ectopic gestation, owing to the four cardinal symptoms of pain, missed period, vaginal bleeding, and the presence of a mass in the right fornix. On laparotomy a typical fimbrial cyst of the right side with a normal ovary and elongated tube was found. The tube, ovary, and cyst were removed and uneventful recovery took place.

MILK FOR MOTHERS AND INFANTS.

CIRCULAR 234 of the Ministry of Health, issued on August 20th, has given rise to some anxiety. A previous circular (No. 185, March 31st) on the subject of the supply of milk by local authorities to expectant and nursing mothers and children under five expressed the view that many authorities were greatly exceeding desirable expenditure on this head. Circular 234 re-states the need for economy, and announces the reduction of the Treasury grant towards such expenditure from 50 to 5 per cent., the outlay in the financial year 1920–21 being taken as the basis on which to calculate this percentage. To comply with the demand for a 20 per cent. cut on expenditure the Maternity and Child Welfare Department was apparently faced with the alternative of economising on the milk grant or of allowing health visitors to be discharged, welfare centres and children's homes to be closed. Restriction of such activities must inevitably lower the standard of the work as a whole and belittle the value of the child welfare movement in the eyes of the public. Milk can still be provided in necessitous cases through the Poor-law; it can still be sold at cost price at welfare centres, where the difference between cost price and the sum the mother can afford to pay will afford a proper object for voluntary contribution. For the mothers dinners may still be provided. And, finally, it is open to authorities which consider there is special need for the distribution of free milk to obtain approval for expenditure in excess of that on which the grant will be paid. We may regret the hardship implied in the limitation and yet feel that the Department has sacrificed the least essential part of its work. The percentage basis, however, hits especially hardly just those local authorities which observed due economy in their expenditure of 1920–21.

SYPHILIS OF THE LUNG.

DR. Udo J. Wile and Dr. Clement H. Marshall,[1] of the Department of Dermatology and Syphilology of the University of Michigan Medical School, remark that in syphilis of the lung, as in syphilis of the gastro-intestinal duct, in which the symptoms closely resemble those of any other gastro-intestinal disease, there is no characteristic clinical picture. It is therefore probable that the condition is more frequent than the clinical or pathological reports would suggest. Indications of the association of syphilis with pulmonary disease are to be found in the writings of Paracelsus, Cesalpinus, and Paro as far back as the sixteenth century, but the first anatomical description of pulmonary syphilis was given by Depaul in 1850, and the first clinical description in 1858 by Virchow whose article on white pneumonia is a classic. Prior to the publication of Koch's epoch-making work on tuberculosis in 1875 enormous numbers of cases of so-called pulmonary syphilis had been published, but after pulmonary phthisis had been recognised as tuberculous, reports of pulmonary syphilis ceased to appear for a considerable time. It is therefore probable that most of the cases reported up till then were those in which syphilis occurred in association with pulmonary tuberculosis or that they were examples of frank tuberculosis mistaken for syphilis. The present writers, from a study of the literature of the last 20 years and personal observations of cases in the University of Michigan Hospital, have come to the conclusion that there is a small group of cases in which there is presumptive clinical evidence of pure among the more expensive articles of food, and an improvement in the quantity and quality of the milk-supply was much to be desired. Vitamins were not produced in animals, but were ultimately derived from green plants, in which they probably arose in large amount in the course of photosynthesis. A good example of this was seen in the recent drought; as the green food became more scarce the vitamin value of the milk was reduced, but after rain had restored the grass there was a rapid recovery. In cows fed on artificial foods, in winter also, the volume of milk was greater, but its nutritive (vitamin) value less than in summer. Some interesting details of the sources of cod-liver oil were described by the speaker, who had recently visited the Norwegian fisheries. Lofoten oil was obtained from the liver of the cod at spawning time (February and March); oil from the Finmarken area was obtained later (June), and was derived from the livers of various other species as well as from the cod. Both were equally potent. The potency of cod-liver oil was remarkable. 2 mg. of oil per day sufficed to supply a rat with vitamin A. If we remember that nearly all of this is fat, the active constituent must be present in minute amount.

[3] Japan Medical World, June, 1921, vol. i., No. 2.

[1] American Journal of Obstetrics and Gynecology, August, 1921.

[1] Archives of Dermatology and Syphilology, July, 1921.

Sir WALTER FLETCHER, in opening the discussion on this paper, remarked that the vitamins were a very good illustration of a most important practical subject which had had its beginnings in purely academic research. The cost of the experiments was heavy and should be borne by the State. It was unfortunate that under the Vivisection Act a special certificate had to be obtained to enable experimenters to feed an animal without an anæsthetic. All these large numbers of animals were well treated, but their numbers were returned and were quoted by anti-scientific societies and used for propaganda work.

Presentation to Sir E. Sharpey Schafer.

Prof. W. D. HALLIBURTON, F.R.S., on behalf of former pupils and assistants of Prof. Sharpey Schafer, now teaching physiology in all parts of the world, expressed their pleasure in congratulating him on his seventieth birthday. He, as one of Prof. Schafer's former students, had seen little change in the young and energetic teacher under whom he studied in 1878 at University College. A presentation in the form of a medallion was to have been made on this occasion, but was not yet completed.

Prof. SHARPEY SCHAFER, in replying, said that he was happy to say that all who had passed through his hands had remained his friends. He, as a former assistant of Sharpey, Burdon-Sanderson, and Michael Foster, had done his best to continue their work, and was happy to see the pupils of his choice still bearing the torch.

Other Communications.

Prof. KROGH (Copenhagen) described a spirometer method by means of which the oxygen consumption of man and animals could be determined. The method should enable determinations of basal metabolism to be made with ease and accuracy.

Dr. W. W. PAYNE and Dr. POULTON described experiments on patients by the balloon method of graphic recording of intragastric pressures, as used by Carlson, which indicated that epigastric pain was due to contraction of the walls of the stomach. Surface tenderness was probably a referred pain. Powerful contractions of the stomach, and also of the œsophagus, resulted when the stomach was distended with gas.

Prof. HALLIBURTON gave a lecture on giants, and dealt chiefly with the effects of hyperpituitarism in the entertaining manner which characterises all of his popular lectures. The subject of dwarfism was also dealt with by way of contrast. Lectures such as the one he gave are always popular at meetings of the British Association, and do much to increase popular interest in the fascinating problems of physiology and medicine.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Health Insurance and Reorganisation of Hospitals.

Twenty-four deputies, including a number of prominent physicians, have elaborated the text of a Bill for the reorganisation of hospitals, for the adoption of a scheme for national health insurance, and a pension for disablement before old age, and have submitted it to the Commission d'Assurance et de Prévoyance Sociales. Sections 1 and 2 of the Bill create at the Ministry of Health a special department, l'Office National, consisting of technical men, physicians, surgeons, architects, and administrators thoroughly acquainted with hospital matters. Its members are to be elected by the Minister from names proposed by various scientific societies. The same sections of the Bill establish county offices working conjointly with the national office. Section 3 gives the function of each country office, which will investigate the need for the construction of new wings to existing hospitals. Such proposed extensions will be classified according to comparative urgency, and the office will censor the plans of any new building to be erected. According to Section 4 the expenses for the erection of buildings declared indispensable will be equally shared by the State, the administrative county, and the municipal borough. The other sections of the Bill deal with health insurance and pensions. Section 5 establishes the principle of a compulsory disablement and health insurance for all employees of both sexes whose salary is Fr.8000 or under. In Section 6 it is proposed that the benefit of the insurance shall not be claimable before the fifth day of the disease, but should the illness last more than ten days the patient would be benefited from the first day. In Section 8 it is suggested that the employer and employee should contribute equally towards the funds of the insurance, the contribution being for each of them 1½ per cent. of the salary, and that the State should contribute to the amount of 50 centimes for every franc. Under Section 10 medical benefit is to consist of medical treatment and attendance, including the provision of medicine and also of a daily unemployment allowance proportional to the salary. Section 11 provides that whenever the insurance doctor is of opinion that the insured person ought to be admitted to hospital, the latter will have to submit to his decision.

French Medical Profession and Inauguration of Pekin University.

On the occasion of the inauguration of the Pekin University in the course of this month Prof. T. Tuffier, of Paris, will, at the request of the Committee of the Rockefeller Institute, give three clinical lectures at the Union Medical College, and he has also been asked to perform a series of operations on three different days. On Sept. 17th Prof. Tuffier will deliver the inaugural lecture at the new university, the subject being Surgical Septicæmias and their Treatment.

International Congress of Hygiene.

The committee of the Propagande d'Hygiène Sociale et d'Education Prophylactique and the Société Française de Prophylaxie Sanitaire et Morale are organising an international congress for the propaganda of social hygiene by instruction on moral education and the prophylaxis of diseases, to be held in Paris during the last week of December, 1922. Mr. Paul Appel, Rector of the Paris University, will preside, and physicians, hygienists, moralists, and all those concerned with the education of the young are invited to the congress; it is hoped that a permanent scheme of action in the prophylaxis of diseases, and more especially venereal diseases, by scientific and moral education of the people, will be worked out. The preliminary programme is as follows: First section: general hygiene, tuberculosis, alcoholism, cancer; chairman—Prof. L. Bernard. Second section: venereal diseases and social consequences; chairman—

orthopædic service (orthopædic registrar). His chief assistant is a surgical registrar, who is also attached for out-patient duties to the "general surgical" services; a third medical officer is provided in the person of the house surgeon of the orthopædic service.

(*b*) *Records.*—The records of all patients attending the clinic are maintained on a special sheet and are kept in a special file separate from the general records of the orthopædic service. In order that adequate notes may be kept on each patient, two secretaries work in the clinic, taking down at dictation full detailed information of the history and results of the physical examination of new patients, and adding continuation notes on the records of old patients. From this department reliable statistics as to end-results should be available in the future.

(*c*) *Splinting.*—It has been found necessary, in order to deal with large numbers of patients at one session, to provide a sufficiency of assistants to the surgical staff, detailed for the special purpose of facilitating the application and reapplication of splints. One or more splint "teams," consisting of pupil masseuses who are under training in the hospital school of physio-therapy, and acting under the direction of the senior masseuse of the hospital, are in attendance. Where necessary, an additional team is formed by the out-patient sister and assistant nurses. In this way in the space of two and a half to three hours from 80 to 90 fractures are seen at the one clinic, and efficient primary splinting or readjustment of splints is carried out.

(*d*) *Physio-therapeutic Treatment.*—The orthopædic registrar in this hospital also holds the office of medical officer in charge of the physio-therapeutic department and its training school. He is thus able to control the patient suffering from a fracture throughout the course of treatment, from primary splinting to the final stage of mobilisation and re-education. This applies also to the senior masseuse and her pupil assistants, so that the arrangement is of considerable educational value to the school of physio-therapy. In this hospital there is thus more than a mere liaison between the orthopædic service and the physio-therapeutic department in regard to the treatment of fractures.

(*e*) *Methods.*—The question of the methods employed in the actual treatment in the clinic does not come within the scope of this article, but it may be said quite briefly that, as would appear from above, splints are used extensively. Plaster-of-Paris fixation is, however, occasionally employed for special purposes—e.g., where abduction of the shoulder-joint is required, or where difficulty is experienced in maintaining by splints the supinated position of the forearm. The splints used almost exclusively are the metal gutter splints of the Liverpool School. As has been mentioned, fractures of the femur or lower leg in younger children, and a certain number of fractures of the lower leg in adults, are treated on the Thomas splint with fixed extension, and such patients are transported from their homes to attend the out-patient clinic in common with the upper-limb fractures. The vast majority of the fracture cases, whilst continuing to attend the clinic, pass into the physio-therapeutic department by the end of the third week, and in a considerable number such treatment is begun within a few days from the time of the incidence of the trauma.

(*f*) *Teaching.*—It is considered that a clinic of this type is eminently suitable for the surgical teaching of both senior under-graduate and post-graduate students. The mass of material can be demonstrated without interrupting in any way the orderly working of the clinic, the actual teaching being in the hands of the surgical director of the service of which the fracture sub-service is a part, who, being able to delegate to others the supervision of the multitudinous details of staff-work, can devote his energies to instruction alone.

General Considerations.

The plan of allocating to one service or—to use a more individualistic British designation—to one surgeon all the fracture patients in a hospital redounds greatly to the credit of those surgeons who, in the interests of efficiency and progress, relinquish the care of these patients. In this connexion the writer is bound to express his appreciation of the whole-hearted coöperation he has received during the past seven years from his surgical colleagues at the Ancoats Hospital.

It is urged that in all general hospitals with not more than about 500 beds a single fracture service organised on similar lines to that which is the subject of this article will be adequate. In still larger hospitals the question of the duplication of this service will arise, but even for the largest general hospital not more than two services should be necessary. With regard to the widespread adoption of this principle of segregation of fractures, it is important to consider certain fundamental requirements. In the first place it is useless to "dump" a vast crowd of patients on to a particular surgeon, unless he is to be allowed a comparatively large staff of assistants, if possible chosen and trained by himself. Failing this provision the creation of a fracture service tends merely to propagate on a large scale all the deficiencies and blunders of the old scattered system. Further, no lasting advances in surgical organisation can be achieved if such a service is placed in a very subsidiary position by delegating it to the care of a junior surgical officer whose interest in fractures is of a temporary nature, and who is looking ahead to the days of promotion and to an active participation in some other surgical field. It is essential that the director of this department be a surgeon in full charge of a service at the hospital, and one in whose practice, teaching, and field of investigation the treatment of fractures will remain an integral part during the whole of his active career. If we are competent to visualise the future development of surgery, abroad and also in this country, we are compelled to affirm that the appropriate surgeon to be entrusted with the control of an ideal fracture service is that specially trained type of general surgeon who is justly accorded the title of orthopædic surgeon. Thus the fracture service of a hospital will naturally find its place as a department of a surgical service which deals with a field which, for want of a more accurate etymological term, is recognised all the world over as orthopædic surgery. This condition applies only to the choice of the director of the service; the surgical assistants can with advantage include junior surgeons whose connexion with the service will be one of a short term of years, and who are to be the future heads of general surgical services.

In a hospital where a second fracture service is deemed necessary, this will be controlled by the chief of one of the general surgical services who is prepared to devote the necessary time and interest to the direction of this work. It is unnecessary to elaborate the obvious economic importance to industry in general of the efficient treatment of fractures. Those who are engaged actively in this work are aware of the fact that employers, insurance companies, and trade-unions are alive to the necessity for reform.

FOOD EDUCATION SOCIETY.—The Food Education Society has issued an appeal for £20,000 to put its organisation on a firm footing, and to enable the many demands made upon its attention to be met in an adequate manner. The giving of cookery lectures, lessons, and demonstrations, participation in exhibitions and conferences, questions to Parliamentary and other candidates, and the publication and circulation of literature throughout the British Empire, are amongst the activities of the Society, which was founded in 1908, and has ever since that time been engaged upon a work proved to be of great national importance during the recent war, and remains an urgent necessity in the face of present financial and social crises. The small amount of capital belonging to the Society is now exhausted, and the public in general, together with social reformers in particular, are confidently appealed to for support. Donations and annual subscriptions should be addressed to the Hon. Treasurer, Sybil, Viscountess Rhondda, D.B.E., Food Education Society, Danes Inn House, 265, Strand, London, W.C. 2; cheques to the order of the Food Education Society, and crossed "Barclay's Bank, Ltd."

Public Health Services.

Reduction of the Capitation Fee.

According to the lay press there is to be a raid on the capitation fee payable to medical men working under the National Insurance Act. The capitation figure was fixed at 11*s.* on March 5th, 1920, by an arbitration between the Insurance Acts Committee of the British Medical Association and the Ministry of Health, the fee being considered to "afford fair remuneration for the time and services" given by practitioners under the regulations for medical benefit. The Minister of Health stated in the House of Commons at the time that the award had been received on both sides with the utmost goodwill. It was then understood that there was no finality about the capitation basis and that after the year 1920 notice of not less than three months might be given to vary the terms and conditions of service, to alter the basis of remuneration, or to repudiate service altogether by organised effort. Since that date panel practitioners have settled down to fulfil their share of the contract, leaving improvement in the remuneration to be considered at a more convenient season. The *Times* of Sept. 6th said that it was argued that the capitation fee might be brought down to 9*s.* 6*d.* without seriously interfering with the health of the country, no intimation being given by whom it was being argued. The *National Insurance Gazette* for Sept. 3rd states that there are proposals to cut down by 2*s.* 6*d.* the Treasury grant of 3*s.* 6*d.* paid to the doctors in respect of medical benefit; and again on Sept. 10th, that the Treasury is "determined in its course of action." The assumption apparently is that the Treasury grant was increased from 2*s.* 6*d.* to 3*s.* 6*d.* at the time the capitation fee was raised to 11*s.* As a matter of fact the new figure has never been split up into its constituent parts as the original capitation fee was. If the 11*s.* fee was granted on the ground of increased cost of living there may be a case for reduction if and when the medical man's cost of living is reduced. On the other hand, the increased responsibilities, the improvement in the nature of the services, and the keeping of records, are all grounds for maintaining the fee at its present level.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Nuneaton.

In his report for 1920 Dr. A. Middleton Hewat tells us that a new infant welfare centre has been opened during the year; that the enlargement of the fever hospital so as to admit diphtheria has been postponed, although the case fatality of diphtheria during the last eight years has been 20 per cent.; that a Bill is now before Parliament to secure an additional water-supply through the Leicester Corporation; and that steps are being taken to improve the overworked sewage works and the affluent therefrom. He describes Nuneaton as essentially a working-class town. Of the 8373 houses, 5102 have been built since 1891. A very large proportion of the working-class houses possess gardens, and the number of allotments under cultivation in the borough, exclusive of railway allotments, is 2929, with an acreage of 291. With an adult male population of about 13,000, this means a large proportion engaged in healthy outdoor occupation. Good health statistics may therefore be anticipated.

The estimated population for 1920 was 41,128; the birth-rate was 29·5 in 1920 and 22·7 in 1919; the death-rate was 9·6 in 1920 and 10·9 in 1919; the infant mortality rate is not so good—viz., 83, in comparison with 80 for the 148 smaller towns. The diarrhœa rate was 7·6 per 1000 births, as compared with 7·8 for the 148 towns. The tuberculosis death-rate was 0·62 for pulmonary and 0·26 for other forms. Dr. Hewat thinks this cannot be looked upon as excessive under present conditions in an industrial town where a large proportion of the population is engaged in coal-mining. But low phthisis rates are the rule among men in coal-fields, and coal-mining districts are practically the only parts of England where the female phthisis rate is equal to or exceeds the male.

Nuneaton has still privies to convert and privy-midden tips to abolish. Dr. Hewat comments on the uncleanliness of the milk-supply, in which respect Nuneaton is like the rest of the country. Dr. A. A. Wood, the M.O. for infant welfare, mentions that the system of having "one delivery" in the day instead of two means that the milk is often 36 hours old when used, and this has counterbalanced any little improvement that may have been secured by greater cleanliness. Dr. Wood comments on the almost complete disappearance of the atrophied infant, and says that rickets has become uncommon in spite of the wide use of dried milks, particularly during 1917, 1918, and 1919. Only about 6 per cent. of the children are vaccinated. Dr. Hewat reports the usual overcrowding, shortage of houses, long waiting list for corporation houses, and difficulty in getting repairs done.

Spenborough.

The urban district of Spenborough came into existence in 1915 by the amalgamation of Cleckheaton, Liversedge, and Gomersal, and includes a portion of the Yorkshire coal-field lying to the west of a line joining Bradford and Dewsbury. The trades of the district show great variety. The estimated population for 1920 was 31,241; the birth-rate, only 16·4 for the preceding five years, rose to 20·1 in 1920, a figure still low for an industrial district. The death-rate was 12·3, and included 19 deaths from influenza. The infant mortality rate was 82·8, slightly above the rate for the whole country, and of the 52 infant deaths no less than 33 occurred in the first four weeks. The diarrhœa rate under 2 years of age was low, only 1·6 per 1000 births, as compared with 7·8 in the 148 smaller towns. This no doubt, Dr. Lawrence Pick says, was largely due to the exceptionally cold and wet summer. The tuberculosis rate was 1·0. Five cases of ophthalmia neonatorum were notified, but no mention is made of permanent damage to eyes.

In regard to housing, Dr. Pick says there can be few districts more urgently in need of new houses; 12 per cent. more houses are required, and a large number should be condemned. There are many back-to-back houses, and owners are obviously unwilling to spend a sum of money on repairs equal to five or six years' rent or more. Much delay has taken place in the housing scheme. The first tender for the A1 non-parlour type was £1291 4*s.* 5*d.* After much conferring the figure became £909 towards the end of the year. Good progress is now being made with 50 houses. Two health visitors were appointed in July, in addition to one appointed in 1916, but no centre has yet been opened. The three health visitors also act as school nurses.

Heston and Isleworth.

A pleasing feature in Dr. W. A. Berry's report is the evidence of coördination of health services. Thus one committee performs the duties of the Health Committee, the Medical Inspection Sub-committee of the Education Committee, and the Maternity and Child Welfare Committee. The area is divided into five districts, and one "health nurse" acts as school nurse and health visitor for each district. Dr. Berry is school medical officer. His assistant, Dr. Eva Roberts, whose duties are mainly in connexion with school children, has charge of one child welfare clinic, in which antenatal work is dealt with. As in other urban districts, the local authority is not the supervising authority of the midwives. The medical officer of health does not therefore receive notification of "inflammation of the eyes,

Membership.

Cards of membership, bearing the date, will be issued for the first day of each month to those whose applications have been made during the preceding month, and the benefits begin on the date named on the card, and continue for one calendar year. These cards must be produced as evidence of membership. At the end of one year from the date of issue of the membership card the benefits cease unless the subscription has been renewed. Fourteen days' grace will be given for renewal (during which none of the services provided will be available). When the number of members has reached the limit of the capacity of the coöperating hospitals the list will be closed. In order that members may be fully assured of the promised services, and also that the capacity of the hospitals may not be strained, the committee have decided to limit very strictly the numbers of those admitted to membership. Applications from those wishing to join the Scheme will be dealt with in the order in which they are received until it is necessary to close the list.

All applications and inquiries should be addressed to the Hon. Secretary, 77, Cambridge-terrace, Paddington, London, W. 2.

BRITISH ASSOCIATION AT EDINBURGH.

SECTION OF PHYSIOLOGY.

THE Presidential Address was delivered by Sir WALTER M. FLETCHER, F.R.S., on

The Aims and Boundaries of Physiology.

This address, in abridged form, appeared in THE LANCET of Sept. 10th, p. 541. A new feature of this year's Association meeting was the discussion on the addresses of Sectional Presidents.

In opening the discussion Sir EDWARD SHARPEY SCHAFER, F.R.S., laid great stress on the fact that a divorce of the teaching of histology from that of physiology would be deplorable. Histology could only effectively be treated as an integral part of physiology, since all the real problems of histology were of a physiological nature. Nearly all the important advances in histology had been made in the course of physiological inquiries. Physiology must be regarded as a science of independent standing, and not merely as ancillary to the study of medicine; its truths were to be sought for their intrinsic scientific value, as the ultimate practical importance of any discovery could never be forecasted. Regarding the application of physiology to clinical medicine, and the recent tendency to summon the physiological expert to the bedside, Prof. Sharpey Schafer was of the opinion that this was impracticable. It was far more desirable for the clinician to so far understand physiology as to be able to apply its findings for himself, or else to be able to propound definite problems for solution in the physiological laboratory. This end could be achieved if young physicians would serve a term of apprenticeship in the Physiological Department similar to that customarily passed through in the dissecting room by their surgical colleagues.

Prof. A. KROGH said that in Copenhagen there were three chairs of Physiology, one in Human and General Physiology, one in Veterinary Physiology, and one in relation to Agriculture, and the arrangement worked well.

Prof. F. G. HOPKINS, F.R.S., drew attention to the importance of both analytical and synthetical methods in the study of all biological problems.

Prof. J. MEAKINS supported Prof. Sharpey Schafer, and was of the opinion that a wider instruction in physiology would be of great value to those practising clinical medicine, which was based on physiology; any great lengthening of the medical curriculum was, however, to be avoided.

Profs. A. D. WALLER, F.R.S., A. R. CUSHNY, F.R.S., J. S. HALDANE, F.R.S., and H. E. ROAF also spoke on the aims of physiological teaching in relation to practical medicine.

Kidney Deficiency Tests.

A discussion on the results of kidney deficiency tests in relation to the views on the functions of the kidney was opened by Prof. CUSHNY, who summarised the results of recent work on renal efficiency tests. In tests which depend on the determination of the relative concentration of some constituent—e.g., water, chloride, urea, sulphate, phosphate, or creatinine, in plasma and in urine—it was essential to distinguish between threshold and no-threshold substances. The first two-named above were threshold substances, and there was some recent evidence that urea was also in the same class: these substances were removed from the blood plasma until their concentration therein reached a definite limiting value. Urea when injected is only slowly excreted and is an unsuitable substance to use as a criterion of kidney efficiency. Sulphate, phosphate, or creatinine being no-threshold bodies—i.e., being finally completely removed by a normal kidney from the blood plasma—might be better. The method depending on the determination of urea content of the blood, which is normally 0·02–0·04 per cent., was unsatisfactory, because the limit of 0·04 per cent. was usually only exceeded when the kidneys were badly failing. In any case, determinations of any substances in the urine (sulphate, creatinine, or injected dyes) were almost useless unless the concentrations of these substances in the plasma was also known.

Prof. MEAKINS agreed with Prof. Cushny that considerable concentrations of urea could be present in the blood without producing marked symptoms. He then gave examples of clinical cases of chronic obstructions due to enlarged prostates, which tended to show that the secretion or retention of water, chlorides, and nitrogenous substances varied independently of one another. Nitrogen retention alone was not of great significance. A study of the volume of urine, and of the chloride and residual nitrogen of the plasma was often a useful guide to indicate whether operation was feasible or otherwise.

Prof. HALDANE was also of the opinion that urea was a no-threshold substance. As regarded the secretion of water, he thought that the kidney very accurately regulated the osmotic pressure of the blood plasma, but that its threshold value was abnormal when the kidney was subjected to back pressure.

Prof. P. T. HERRING showed photomicrographs which he believed indicated that in the kidneys of some lower vertebrates, at all events, the uriniferous tubules definitely secreted.

Prof. KROGH and Prof. T. H. MILROY also emphasised the opinion that urea was a no-threshold substance, and that urea was normally present in the tissues.

Dr. C. LOVATT EVANS suggested that an effect of obstruction and back pressure might be to cause local vascular changes in the kidneys, and thus to direct blood to different extents to portions of the uriniferous tubules of different functions, absorptive or secretory.

Dr. E. P. POULTON pointed out that in azotæmic nephritis, though urea was retained, chloride was not.

Sir J. MACKENZIE thought that too little attention had been given to the correlation between kidneys, skin, and bowel: further, that in nephritis some substances of unknown nature were retained and produced symptoms.

In replying, Prof. CUSHNY said that the effects of obstruction in producing alterations in urinary volume were almost certainly of a reflex nature.

Vitamins in Relation to Public Health.

Dr. J. C. DRUMMOND read a paper on the relation of vitamins to public health. The danger of an inadequate supply of these protective foodstuffs in the dietary of the working classes had by no means been overrated; their consumption of milk, fruit, and green vegetables was low, and much of their food had been subjected to unnatural processes of preservation. Most of the sources of vitamins were

Stockport.

Of 5668 elementary school children submitted to routine medical examination 33·85 per cent. were found defective. 8·7 per cent. were found suffering from enlarged tonsils and adenoids, and two-thirds of this number were referred for operative treatment. 12·94 per cent. had defective vision, 1·55 per cent. had otorrhœa, and, in addition, 2·82 per cent. suffered from deafness—"largely the result of untreated tonsils and adenoids." During the year treatment was received by just over half the number requiring it. The addition of a school dentist to the medical staff has been a step forward. There are no nursery schools. A scheme for effective supervision of physical education and for inaugurating the treatment of remedial defects has been approved by the authority. Seventy-five children per meal attended the feeding centres, as against 37 during the previous year. These children are weighed once a fortnight.

THE R. W. MICHELL MEMORIAL.

It has been suggested by many of his old friends that some form of permanent memorial should be instituted at Cambridge in memory of the late Dr. R. W. Michell, who lost his life in July, 1916, as a result of wounds received whilst rescuing wounded on the Somme. After holding a demonstratorship in anatomy in the University, Michell remained in Cambridge, where his practice was chiefly among the undergraduates and younger graduates. His keenness and energy, his enthusiasm for the young life of the University, his desire to give the best of his experience to those who needed it among active undergraduates, endeared him to successive generations. Heart strain was one of the conditions he particularly laboured to understand, so that he might guide aright the natural bent of the sporting man. He was one of the first practitioners to make use of the electro-cardiograph as a regular routine in his clinical practice. As at one time he captained the College boat at Caius, and continued to take an unselfish interest in Cambridge rowing, it is proposed that the memorial should take the form of a challenge cup, to be awarded every year to the successful College Boat Club in the Lent and May races, and in various annual rowing and sculling events. Subscriptions, limited to £2 2*s.*, may be sent to Dr. C. H. S. Taylor, 3, Trinity-street, Cambridge.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lieut. A. C. Anderson to be Surg. Lieut.-Comdr.

The following appointments have been made:—Surg. Comdrs.—P. M. Rivaz to R.N. Hospl., Chatham; G. A. S. Hamilton to *Vivid* for Youths' Training Establishment; W. P. Walker to *Victory* for R.N. Barracks (temp.); W. H. Edgar to *Wildfire* for Sheerness Yard and Barracks; F. H. Hall to *Renown*; R. R. Horley to *Pembroke*, addl., for R.N. Barracks (temp.): and S. F. Dudley to *President*, addl., for Greenwich College, and as Prof. of Clinical Pathology.

Surg. Lieut.-Comdrs.—P. B. Wallis to *Colleen*, addl., for Haulbowline Hospl. and Yard; J. Kirker to *Wildfire*, and for Sheerness Yard; E. MacEwan to *Titania*; C. H. M. Gimlette to *Ambrose*; and A. Fairley to *Cordelia*; R. J. G. Parnell, A. G. V. French, M. C. Mason, S. W. Grimwade, A. B. Clark, and M. J. Aitken to *President*, addl., for five months' course of instruction to join R.N. College, Greenwich.

ROYAL ARMY MEDICAL CORPS.

The King has approved of the following appointments:—To be Colonels Commandant: Lieut.-Gen. Sir A. Keogh, Hon. Col. R.A.M.C., T.F.; Lieut.-Gen. Sir A. T. Sloggett; Maj.-Gen. Sir T. J. Gallwey; Surg.-Gen. Sir F. W. Trevor.

Lieut.-Cols. A. W. Hooper (granted the rank of Col.) and B. W. Longhurst retire on ret. pay.

Lieut.-Col. D. Lawson is placed on ret. pay.

Maj. W. R. O'Farrell to be temp. Lieut.-Col. whilst spec. empld. as A.D. of P.

Capt. D. T. M. Large to be temp. Maj. whilst spec. empld. as D.A.D. of P.

Capt. W. H. Dye is secd. for service under the Colonial Office.

Temp. Capts. relinquish their commns.: F. K. Kerr (granted the rank of Lieut.-Col.), E. Lauzon and W. S. Angus (retain the rank of Capt.).

ARMY DENTAL CORPS.

Flight Lieut. G. F. Charles, from R.A.F., Dental Branch, to be Capt.

Temp. Lieuts. G. Hepburn and A. R. B. Littlar relinquish their commns. on ceasing to be employed as dental surgeons and retain the rank of Lieut.

TERRITORIAL FORCE.

Maj. A. Bird, having attained the age limit, is retired and retains the rank of Major, with permission to wear the prescribed uniform.

Maj. H. H. B. Cunningham to be D.A.D.M.S., 53rd (Welsh) Divn.

Capts. E. F. Skinner and T. M. Jamieson to be Majs.

Maj. A. J. Gibson (late R.A.M.C., Spec. Res.), to be Capt., and relinquishes the rank of Maj.

Capt. J. L. Lawry (late R.A.M.C.) to be Capt.

Capt. S. McNaughton (late R.A.M.C.) to be Lieut., and relinquishes the rank of Capt.

Lieut. D. C. Graham to be Capt.

2nd Lieut. A. Pain (late Tank Corps) to be Lieut.

A. S. Pern to be Lieut.

1st W. Gen. Hosp.—Capt. W. Permewan, having attained the age limit, is retired, and retains the rank of Capt.

TERRITORIAL FORCE RESERVE.

Col. J. A. Jones, having attained the age limit, is retired, and retains the rank of Col., with permission to wear the prescribed uniform.

INDIA AND THE INDIAN MEDICAL SERVICE.

Maj. F. T. Thompson to be Lieut.-Col.

Major (retd.) to be Lieut.-Colonel (retd.): M. Dick.

The King has approved the retirement of Lieut.-Col. H. J. Walton.

The King has approved the relinquishment of their temp. commns. by the undermentioned, and the grant of rank as specified below: Capt. Sham Lal, Capt. Jatindra Mohan Mitra, in consequence of ill-health. And are permitted to retain the rank of Capt.: Harmusji Framji Maneckshaw, Dattatraya Mahadeo Bhatavadekar.

Donations and Bequests.—The committee of the Christie (Cancer) Hospital, Manchester, has received the following bequests: Miss M. E. Adshead £567, Miss Sophia Benger £500, Mr. William Sutcliffe £200, Miss Emily Scown £100.

National Hospital for the Paralysed and Epileptic.—A syllabus of post-graduate work for the term October–December has now been issued. Three courses will be given at the Hospital: 1. A course of clinical lectures and demonstrations will comprise attendance at out-patient clinics at 2 P.M., on Mondays, Tuesdays, Thursdays, and Fridays, followed at 3.30 P.M. by lectures delivered by Dr. Hinds Howell, Dr. F. M. R. Walshe, Dr. Grainger Stewart, Dr. Risien Russell, Dr. Farquhar Buzzard, Dr. Gordon Holmes, Dr. J. Collier, Mr. S. Scott, Dr. Russell Reynolds, Mr. D. J. Armour, Dr. S. A. Kinnier Wilson, Mr. P. W. G. Sargent, Dr. P. W. Saunders, Dr. James Taylor, and Mr. L. Paton. Provided sufficient entries are received, two additional courses will be given. Dr. Greenfield will give a course of 10 lectures and demonstrations, at 12 noon, on Mondays, commencing Oct. 3rd, on the Pathology of Nervous System, and a course of 10 lectures will be given on the Anatomy and Physiology of the Nervous System by Dr. Gordon Holmes and Dr. Hinds Howell, at 12 noon, on Fridays, commencing Oct. 7th. A fee of £8 8*s.* will be charged for the clinical lectures and demonstrations, and those taking this course will be entitled to attend the course in pathology without further payment. The fee for the pathological course alone or for the course in Anatomy and Physiology alone is £5 5*s.* Holders of the Fellowship of Medicine ticket for the National Hospital will be admitted to the clinical lectures and demonstrations and to the course in pathology.

Further information can be obtained from Dr. C. M. Hinds Howell, Dean of Medical School, Queen-square, Bloomsbury, London, W.C. 1.

Prof. Ed. Jeanselme. Third section: prophylaxis of venereal diseases; chairman—Mr. L. Queyrat. Fourth section: instruction in sexual matters; chairman—Prof. A. Pinard. Fifth section: *means of action*, propaganda, legislative measures; chairman—Mr. J. Godart. Anyone seeking further information concerning the congress is invited to write to the General Director of the Congress: Monsieur Sicard de Plauzoles, 6, rue de Logelbach, Paris (17e).

International Congress for the Protection of Motherhood and Infancy.

An International Congress for the Protection of Motherhood and Infancy will be held in Paris on July 6th, 7th, and 8th, 1922. The programme of questions open to discussion is the following: Section 1: Protection of the mother before and during confinement. (*a*) Consultations during pregnancy. (*b*) Management of confinement at home. Section 2: Protection of mothers who suckle their children. Section 3: Protection of the infant when weaned from its mother. Section 4: Assistance and teaching. In the course of the meeting an International Association for the Protection of Motherhood and Infancy will be organised. Foreign societies are invited to send a delegate to express their opinion on the questions set forth. Individuals desiring to be present, as well as societies wishing to send representatives, are invited to communicate with the President, Union des Œuvres d'Assistance Maternelle et Infantile, 49, rue de Miromesnil, Paris.

Sept. 10th.

INDIA.

(FROM OUR OWN CORRESPONDENT.)

Vaccination in Madras Presidency.

THE campaign against small-pox has for many years been a very important part of the work of the Sanitary Department all over India. In the Madras Presidency, in fact, up till 1914 or later, the Deputy Sanitary Commissioner spent the greater part of his time inspecting vaccination in the various districts and checking vaccination returns. In spite of constant vigilance the results obtained were unsatisfactory, the percentage of successes gradually falling lower and lower. At first this loss of efficiency was laid at the door of the district vaccinators and the deputy inspectors of vaccination, who were harassed and fined until it was realised that perhaps the vaccine lymph might have something to do with the bad results. All lymph for the Presidency is manufactured at the King Institute at Guindy—some five miles out of Madras City—where the average temperature may be taken to be the same as in the city. The average temperature throughout the Presidency—which in this respect is unlike other parts of India—is never very low; it will be shown later how this militates against success. The position reached can be understood from the following communiqué issued by the Madras Publicity Bureau:—

> "The results of vaccination in this Presidency have not been satisfactory for some years, though other provinces have continued to show good results. In order to discover the causes of this deterioration, the Government deputed Major J. Cunningham, I.M.S., and later Rao Bahadur M. Kesava Pai, M.D., of the King Institute, to visit the lymph depôts in other provinces and report on the methods of lymph production and preservation in these depôts. The investigations of these officers indicate that climatic conditions in this Presidency are unfavourable to the success of vaccination in the hot weather. The experience of other provinces also points to the same conclusions. In the Punjab and in the United Provinces routine vaccination operations on the plains cease during the hot weather, and are resumed as soon as the weather becomes cool. Fresh vaccine lymph has been found to be more effective than lymph issued some time after manufacture, but in practice it has been found impossible to manufacture lymph at the King Institute during the hot months, with the result that fresh vaccine can only be issued from the Institute if vaccination is confined to the cooler months. The small-pox returns of the last ten years also indicate that the disease is most common between January and May, and that if vaccination were restricted to the cooler months, it would anticipate the period of greatest mortality which would be of considerable advantage.
>
> "Having regard to all these considerations, the Surgeon-General has strongly recommended a total cessation of routine vaccination work in the plains during the hot season except in cases of emergency, such as the presence of small-pox in an epidemic form. The Government approve the Surgeon-General's proposal. They accordingly direct that the supply of vaccine lymph from the King Institute shall cease during the months of May and June. The Government trust that it will be possible for the local bodies to employ the vaccination staffs usefully in other ways, such as checking records and registration of births and deaths during the two months when vaccine operations are suspended."

A further investigation into the average temperature showed that the south-west monsoon had no effect on many parts of the Presidency, and accordingly the Government have also agreed to the suspension of vaccine operations during July and August in such areas. This will give the King Institute a better chance of providing fresh vaccine lymph during the cooler months. Another important problem which has not yet reached a satisfactory solution is the method of transporting the lymph. At present it is packed up in small cardboard boxes and is distributed through the post. In many instances the lymph takes three days to reach its destination, and the high temperatures to which it is exposed cause a rapid deterioration in its potency. Various suggestions have been made, none of them very satisfactory, but it is obvious that until the lymph is packed in such a manner that it is maintained at a moderate temperature, it will never give a very high success rate.

The Sanitary Department in Madras.

As recently as 1914 the Sanitary Department consisted of the Sanitary Commissioner and one deputy for a population of 46 millions. In 1918 two more Deputy Sanitary Commissioners (D.S.C.'s) were appointed, and the Presidency was divided into three ranges, one D.S.C. for each. In 1920 a fourth appointment was made in order to permit of the senior D.S.C. being placed on special duty for the sanitary control of fairs and festivals. There are hundreds of sacred temples and shrines in the Presidency, all of which at one time or another attract considerable numbers of pilgrims, whilst some festivals are attended by many thousands of people. Here, obviously, was one of the most important means of spreading cholera, and it was felt that part of the danger might be averted. During the present month, for instance, the Pushkaram festival at Bezwada, which takes place only once every 12 years, and which lasts 10 days, will, it is anticipated, be attended by something like 1½ millions of people. For a town whose normal population is about 55,000, and from which run several large canals fed by the River Kistna, this enormous addition to the population constitutes a tremendous danger. Arrangements for sanitary control, for medical inspection of the pilgrims, for provision of additional water-supply and food, for temporary housing, hospitals, &c., have been in progress for the past six months or more under the guidance of the senior Deputy Sanitary Commissioner. Experience has already shown that this form of preventive work can be made very successful, for during another large festival, held in May of this year, not a single case of cholera occurred. Such extraordinary success may not always be possible, but it nevertheless demonstrates what can be accomplished by forethought and organisation.

The Secretary of State has recently sanctioned two more D.S.C.'s—i.e., six in all—a remarkable increase in the short space of seven years; but it is not to be supposed that the number is excessive. The work which lies waiting to be done could absorb the energies of twice six, and it is somewhat difficult to decide what problems most urgently require attention. The local Government has decided that in future D.S.C.'s shall be recruited from the provincialised Health Officer Service, so that it will now be possible for a Madras graduate to rise to the post of Sanitary Commissioner, the head of the Sanitary Department. It is believed and hoped that with this extension of activity the terms "Sanitary Commissioner" and "Deputy Sanitary Commissioner" will be replaced by the more correct and significant titles of "Director of Public Health" and "Assistant Director of Public Health."

concerning "catarrh," considering the nervous cases and epidemics of their time as alternative manifestations of the disease otherwise responsible for the cases and epidemics of respiratory and gastro-intestinal catarrh which make up for us so great a part of what we call influenza. It was on precisely similar clinical and epidemiological observations that Boström, in 1757, based his identification of the "new disease" at Upsala with the epidemic and catarrhal fever, of protean nature, to which the name of influenza was then being elsewhere attached. It was again on precisely similar grounds that Brorström, in 1910, founded his thesis of the relation between epidemic poliomyelitis and influenza.

There is, indeed, only one "disease" to which we can refer the picture so graphically outlined by Dr. Gardner and that is influenza—in the epidemiological if not the bacteriological sense. What we call epidemic influenza has been consistently described for some 500 years now, as always, "new in character." Yet, as Boström said, "Hic morbus non est novus."

I am, Sir, yours faithfully,
F. G. CROOKSHANK.
Wimpole-street, W., Sept. 10th, 1921.

THE COUGHING CUP IN THE PREVENTION OF TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—Tuberculosis is spread in only three ways—by milk, spray, and sputum. Milk should be boiled, and the sputum collected in a flask and destroyed. But the chief agent and danger is from the spray given off in the act of coughing. A cavity case sitting at his table, and spraying the food-supply of the family, is probably the most dangerous agent in spreading the disease.

I would therefore suggest the use of *a coughing cup*, in which the spray given off should be collected, and the cup and its contents be boiled each night. A coughing cup is of as much importance as a sputum flask, and all patients with T.B. in their sputum should use one. In a parallel way the central feeding stall in all cow byres should be abolished, as I feel sure it is one of the most dangerous arrangements for spreading tuberculosis amongst cattle—an infected animal coughing infected froth into the face and fodder of the opposite animal.

I am, Sir, yours faithfully,
T. M. ALLISON, M.D.
Jesmond-road, Newcastle-upon-Tyne, Sept. 8th, 1921.

THE TREATMENT OF PNEUMONIA.

To the Editor of THE LANCET.

SIR,—During the last four years I have treated acute pneumonic fever, so-called pneumonia, in the following way. In my list, 255 patients were seen reasonably early; among these there was not a single death, no complications, and no case which caused me anxiety. Only amongst those coming under treatment late in the disease, when heavily toxic, did I find cause for anxiety or had deaths. The majority of my cases were Europeans, the rest were Asiatics with a few natives. Many of these were in the influenza epidemic of 1918 and were particularly malignant. Pneumonia here is certainly of as severe a type as in Europe.

The principles of treatment were: 1. Not to allow the temperature to rise above 101° F. 2. To reduce blood pressure. 3. To combat acidosis. 4. To keep the kidneys and bowels active. 5. Starvation. 6. No stimulants. 7. Thoroughness. No. 1 was carried out by having the body continuously naked and wet on a waterproof sheet, in a draught of air, varied in severity according to the mouth temperature at the time. No. 2 by bleeding (a pint or so according to the patient), by calomel, or by both. Bleeding was done very early, never late (when done early apparently only toxins are removed, when late antitoxins are also taken away). No. 3 by giving gallons of water to drink a day, by citrate of potash, bicarbonate of soda, lemon-squash and sugar. No. 4 by the above and by calomel in minute doses often. For the first 24 hours the patients were purged severely. For toxic cases, seen late, reliance was mostly placed on severe purgation immediately and the doing away with acidosis. No. 5 sugar was the only nourishment given until the fever was gone and until the patient became hungry. No. 7 treatment was not changed or modified for the wishes of the patient or of friends; it was directed to save life.

This skeleton of treatment is intended to elicit interest and trial by others. All other fevers, irrespective of the cause, have been treated on the same general principles with much the same results. These results have convinced me of the correctness of the Johns Hopkins principle, that antitoxins are not satisfactorily formed in the presence of a high temperature. I am, Sir, yours faithfully,
R. W. BURKITT.
Nairobi, Kenya Colony, July 30th, 1921.

THE REFRACTORY IRIS.

To the Editor of THE LANCET.

SIR,—The interesting annotation on Refractory Iris in your issue of Sept. 10th seems to me to lead to a very important question. Mention is made in the paragraph just cited of the fact that in certain races there are no crypts in the iris. It would be very important to ascertain if these races are more subject to glaucoma than others. Perhaps some of your readers who have opportunities of gathering statistical data on the subject would do so, and thereby render an important service to ophthalmic science.

I am, Sir, yours faithfully,
Glasgow, Sept. 12th, 1921. FREELAND FERGUS.

VERONAL AGAINST SEA-SICKNESS.

To the Editor of THE LANCET.

SIR,—The Channel passage used for many years to be a misery for me, as I suffered acutely from sea-sickness and once for days after from so-called land-sickness. During the last eight or ten passages I have taken veronal and have never been sick, even though the majority of the passengers succumbed. I have a light meal before going on board and take 8 gr. of veronal or its sodium derivative, which, being soluble, acts faster. I pass the first hour, and if rough the whole passage, in the recumbent position on deck. Many patients have also derived benefit, some even during longer voyages, by taking 2–3 doses a day for a couple of days.

I am, Sir, yours faithfully,
Zurich, Sept. 9th, 1921. THEODOR ZANGGER, M.D.

Obituary.

THOMAS ARTHUR HELME, M.D., F.R.S. EDIN., M.R.C.P. LOND.,

CONSULTING PHYSICIAN, NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, MANCHESTER.

WE referred briefly in our last issue to the death of Dr. T. A. Helme, which occurred on Sept. 5th at Rhosneigr, Anglesey. Thomas Arthur Helme was the fifth son of Mr. James Helme, of Lancaster, and the brother of Sir Norval Helme, Dr. James Milner Helme, of Silverdale, and Dr. G. Edgar Helme, of Rusholme, with the two latter of whom he received his medical education at the University of Edinburgh at a time when Sir William Turner was professor of anatomy. Sir William Turner, himself a Lancaster man, took a great personal interest in his young fellow-townsmen. T. A. Helme had a distinguished career as a student; taking his M.B. and C.M. with honours in 1885, he gained the Buchanan Scholarship however slight," in accordance with the rules of the C.M.B. He receives later the notification of the case as "ophthalmia neonatorum" if the medical man called in considers it to be such, but the method may cause dangerous delay. Dr. Berry instances cases of inflammation of the eyes discovered by the health visitors, with regard to which complaint was made to the county supervising authority that the midwife had failed to observe the rules. Eight cases of ophthalmia were notified. Three were nursed in an institution, and of these one was discharged blind in both eyes. It will naturally be asked whether there was delay in getting adequate treatment for this case.

The population of Heston and Isleworth for 1920 was 43,445 for birth-rate and 41,945 for death-rate; the birth-rate was 24·7; the death-rate was 10·9; the infant mortality rate was 58. There appears to be an unusual demand for antenatal advice and a prospect of a flourishing antenatal clinic. A home-help was appointed in 1919, and her services have proved very useful. During the year she paid 328 visits to homes for the purpose of rendering assistance. The school report shows that treatment of the defects found is being provided in a systematic manner, but that in a considerable proportion of cases the services of the school dentist were refused. Dr. Berry mentions that there are no facilities for open-air education, and that there is, as yet, no organiser of physical training for the elementary schools in the district.

SCHOOL MEDICAL SERVICE.

Liverpool.

IN Liverpool the close coöperation between the public health and allied services is agreeably noteworthy. Nearly 50,000 children are dealt with annually at the routine examinations, at which last year about 45 per cent. showed some defect. Tonsils and adenoids requiring treatment accounted for 3·1 per cent., while 6·4 per cent. were kept under observation—"the very gross cases are now, fortunately, very seldom met with." Only seven definite and 30 doubtful cases of pulmonary tuberculosis were found during these examinations, and Dr. E. W. Hope reports that at the end of the year the total number of such cases under observation was 438, all of which had been excluded from school. Besides these, there were 365 cases of non-pulmonary tuberculosis, 81 of which attended the public elementary and 108 the physically defective schools. Four open-air residential schools, with 376 beds between them, are available for these children. There appears to be no open-air day school.

On the list of nurses three women are returned as dental helpers; we look forward to many more of these before long. The sound principle is followed of treating school children and children of pre-school age in the same building. In tabulating the results of cleansing "in conformity with the Board's instruction," boys and girls are not differentiated, which, of course, makes the results numerically valueless, the figures depending on the distribution of boys and girls rather than on cleanliness and uncleanliness. A difficulty in accounting for the increase in ringworm cases seems to have been felt, but years ago it was pointed out that this disease ebbs and flows like one of the zymotics. Scabies here, as elsewhere, still remains a legacy of the war, the number of absentees during the year from this cause being the highest on record. The average attendance at Liverpool's six clinics of 122 on school days dwindles to eight on Saturdays, which shows Saturday working to be hardly worth while. During the year 377 new and 1576 old cases of defective vision were seen at the clinics, while 2376 new cases were treated by the nine private doctors who undertake the work at a fee of 7*s.* 6*d.* per head. An inquiry extending over several months elicited the fact that out of 3036 children, 36 per cent. were not wearing their glasses. In 11 per cent. of the cases the glasses had been broken or lost; as to the remainder, the glasses had either been forgotten or, as is more probable, the children did not like wearing them. Here, as everywhere else, it is most difficult to get a hypermetropic child to wear glasses. Experience has shown in Liverpool that the amblyopic eye remains amblyopic in spite of all remedial measures tried. Nothing useful can be done in such cases, and from the public health point of view it is not worth while making the attempt. Two sight-saving classes deal with 18 per cent. of cases requiring such special educational treatment. Additional classes have been authorised, and it is hoped that they will soon materialise. Children attending voluntary schools are precluded from attending these classes, however serious their eye condition may be, without special permission of the committee, on the written application of the parent.

The extensive survey of cripples sets out full statistics of 1770 cases between 5 and 14 years of age, but does not bring out clearly the epidemic of poliomyelitis, which appears to have occurred in Liverpool between 1912 and 1913. Approximately 40 per cent. of the tuberculous cases, 90 per cent. of paralyses, and 92 per cent. of rickets occurred before the age of 5; yet this city has no nursery schools. The Board of Education tables end an interesting and well-considered report.

Isle of Wight.

The number of children who underwent routine examination amounted to 2748. Of these 18 suffered from malnutrition, 677 from dental defect, 145 from defective vision, 27 from defective speech, and 1 from anæmia. There were three cases of definite pulmonary tuberculosis and one suspected case. Out of 1335 children referred for treatment, 517 obtained it. 401 cases of uncleanliness are reported, and in one case the parents were prosecuted and fined for non-attendance, but under the system adopted in the island of making the doctor pay his own travelling expenses it happens that he is fined more frequently than are the defaulting parents.

Ryde.

The total number of children submitted to routine medical inspection was 478. Of these 4 suffered from malnutrition, 124 from dental defect, 4 from defective hearing, 33 from visual defect, and 2 from defective speech. There were no cases of anæmia, nor of tuberculosis, although in one case pulmonary tuberculosis was suspected. 227 children were referred for treatment, and in just under one-half of these cases treatment was obtained. The school nurse paid 95 visits to each school in the borough, and examined each pupil four times during the year. 205 of these children suffered from uncleanliness, and there are no arrangements for cleansing. Dr. J. P. Walker notes that in nine out of ten cases where parents objected to examination, a medical inspection was found to be urgently needed.

Margate.

Of 1117 children submitted to routine examination, 63 required treatment for dental defect and 115 were kept under observation; 11 required treatment for enlarged tonsils and adenoids, 11 for defective hearing, 4 for otitis media, and 5 for defective speech. 153 children obtained treatment for defects of nose and throat under the local authority's scheme, and out of 1256 referred for dental defects throughout the year 1016 were treated. As a result of X ray treatment of ringworm, the period of absence was reduced from 21 weeks to between four and five. Dr. R. McCombe, in reporting on the employment of children out of school hours, records that 42 children were illegally employed, and that several errand boys were working out of school hours between 30 and 40 hours a week. Eleven out of the 42 children showed two to three years retardation in school work. About 20 girls were examined, but Dr. McCombe reports "as their work consisted chiefly of taking out babies and acting as 'mother's help.' I was of opinion that their employment was more conducive to health than otherwise."

Post-Graduate Course on Infant and Child Welfare.—A course of 12 lectures on the Management and Feeding of Infants and Young Children will be given by Dr. Eric Pritchard (physician in charge of the Infant Welfare Department) to qualified practitioners on Wednesdays and Fridays at 6 p.m., commencing Oct. 5th, at the St. Marylebone General Dispensary. Students taking this course will be entitled to attend the Infant Consultations held by Dr. Pritchard on Tuesdays at 11 a.m. and Thursdays at 3 p.m. at the Dispensary. Opportunities will also be afforded to students of visiting the Nursery Training School, 1, Wellgarth-road, Golders Green, on Saturday afternoons. Further information and tickets for the course (two guineas) may be obtained from the secretary, 77, Welbeck-street, Cavendish-square, London, W. 1.

King's College Hospital Medical School.—The opening ceremony of the winter session will be held at 3 p.m. on Friday, Sept. 30th, when the introductory address will be given by the Right Hon. Lord Gorell, C.B.E., M.C.

The annual dinner of past and present students will be held at 7 for 7.30 p.m. on the same day at the Café Royal, Regent-street, London, W., Mr. F. F. Burghard, C.B., senior surgeon of the Hospital, in the chair.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, Sept. 19th.—2 p.m., Dr. S. Pinchin: Medical Out-patients. Dr. Simson: Diseases of Women. Mr. MacDonald: Surgical Out-patients.

Tuesday.—10 a.m., Mr. Steadman: Dental Department. 2 p.m., Dr. Burrell: Medical Out-patients. Mr. T. Gray: Surgical Out-patients. 2.30 p.m., Mr. Addison: Visit to Surgical Wards.

Wednesday.—10 a.m., Mr. MacDonald: Genito-Urinary Department. 2 p.m., Mr. Addison: Operations. Mr. Gibb: Eye Department. Mr. D. Armour: Visit to Surgical Wards.

Thursday.—2 p.m., Mr. D. Armour: Operations. Mr. MacDonald: Surgical Out-patients. Mr. B. Harman: Eye Department.

Friday.—10 a.m., Mr. D. Buxton: Dental Department. 2.30 p.m., Dr. Pritchard: Visit to Medical Wards.

Saturday.—10 a.m., Dr. Burnford: Visits to Medical Wards. 2 p.m., Dr. Owen: Medical Out-patients. Mr. Sinclair: Surgical Out-patients.

Daily:—10 a.m., Visit of Post-Graduates to Wards. 2 p.m., In-patient, Out-patient Clinics and Operations.

Appointments.

Burns, David, M.A., D.Sc., Grieve Lecturer on Physiological Chemistry in the University of Glasgow, has been appointed Professor of Physiology in the University of Durham College of Medicine, Newcastle-upon-Tyne.

Grahame, M. C. R., M.B., Ch.B. Edin., Tuberculosis Officer and Deputy Medical Officer of Health to the Burnley Town Council.

Gunn, R. M. C., M.R.C.V.S., Lecturer in Veterinary Anatomy and Surgery in the University of Sydney.

Landau, J. V., M.B. Lond., M.R.C.S., Anæsthetist at Queen Mary's Hospital for the East End.

Thomson, C. S., M.D. Glasg., D.P.H., Medical Officer of Health of Deptford.

Willan, R. J., M.S. Durh., F.R.C.S. Eng., Consulting Surgeon to the Hexham and District War Memorial Hospital, Hexham.

Williams, P. L. W., L.R.C.P. Lond., F.R.C.S. Edin., to be one of the Medical Referees under the Workmen's Compensation Act for County Court Circuit No. 59.

Wilson, Wm., M.D. Vict. Manch., Aurist and Laryngologist to the Manchester Board of Guardians (Crumpsall and Withington Hospitals and Booth Hall Infirmary for Children).

Vacancies.

For further information refer to the advertisement columns.

Aberystwyth Infirmary and Cardiganshire General Hospital. Res. H.S. £200.

Ayr District Asylum.—Jun. Asst. P. £300.

Birmingham General Hospital.—Res. M.O. £155. H.S.'s. Each £125.

Bournemouth, Royal Victoria and West Hants Hospital, Poole-road Branch.—Res. M.O. £200.

Bridgwater Hospital.—H.S. £165.

Bristol Royal Hospital for Sick Children and Women.—H.S. H.P. Each £150.

Cancer Hospital, Fulham-road, London, S.W.—H.S. £150.

Canning Town Women's Settlement Hospital, Balaam-street, Plaistow.—Female Sen. Res. M.O. £150.

Cardiff, King Edward VII. Hospital.—H.S. £200.

Central London Ophthalmic Hospital, Judd-street, St. Pancras, W.C.—H.S. £100. Jun. H.S. £50.

Chelsea Hospital for Women, Arthur-street, S.W.—Hon. Dental Surg.

Clifton, York, North Riding Mental Hospital.—Sen. Asst. M.O. £400.

Croydon General Hospital.—Vacancy on Hon. Med. Staff.

Derby, Derbyshire Royal Infirmary.—Ophth. H.S. £200.

Dumfries and Galloway Royal Infirmary.—Female Res. H.S. and Res. Phys. Each £150.

Glasgow, Bellahouston Hospital.—Pathologist. £600.

Hospital for Epilsepsy and Paralysis, Maida Vale, W.—Hon. Ophth. Surg.

Hospital for Women, Soho-square, W.—Pathologist and Registrar. £100.

Leeds Public Dispensary.—Sen. Res. M.O. £250.

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—H.S. £200.

Newcastle-upon-Tyne, Wingrove Hospital.—Female Sec. Res. M.O. £250.

Norwich, Norfolk and Norwich Hospital.—H.S. £200.

Notts County Council.—Tuberc. Officer. £750.

Oxford, Radcliffe Infirmary and County Hospital.—H.P. £200.

Plymouth, South Devon and East Cornwall Hospital.—H.S. £200.

Powick, Worcester County and City Mental Hospital.—Sen. Asst. M.O. £500.

Prince of Wales's General Hospital, Tottenham, N.—H.P. H.S. Each £200. Jun. H.S. Jun. H.P. Each £120.

Queen Mary's Hospital for the East End, Stratford, E.—Cas. O. £150.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—H.P.'s. £100.

Rotherham Hospital.—Jun. H.S. £150.

Royal Chest Hospital, City-road, E.C.—H.P. £120. Res. M.O. £200.

Royal Waterloo Hospital for Children and Women, Waterloo-road, S.E.—H.S. £100.

St. Helens Hospital, Lancs.—Res. M.O. £250.

St. Mary's Hospital Medical School, Paddington, W.—First, Second, and Third Assts. in the Med. Clinic. £750, £450, and £350 respectively.

Saint Pancras Dispensary, 39, Oakley-square, N.W.—Hon. Phys.

Salford Royal Hospital.—Res. Surg. O. £250. H.P. £200. H.S. £150. Cas. H.S. £150.

Salisbury General Infirmary.—H.S. £200.

Sheffield Royal Infirmary.—H.S. H.S. for Ear, Nose and Throat. Each £150. Asst. Cas. O. £150.

South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Jun. H.S. £175.

Stoke-on-Trent, North Staffordshire Infirmary, Hartshill.—H.S. £200.

Sunderland Royal Infirmary.—H.S. £200.

Tunbridge Wells General Hospital.—H.S. £160.

Wakefield, Clayton Hospital.—H.S. £225.

West London Hospital, Hammersmith-road, W.—Two H.S.'s. H.P. Each £100. Surgeon.

Winchester, Royal Hampshire County Hospital.—Sen. Res. M.O. £250.

Wolverhampton County Borough Education Committee.—Asst. Sch. M.O. £600.

Wrexham Infirmary.—H.S. £200.

Births, Marriages, and Deaths.

BIRTHS.

Harris.—On Sept. 9th, at Holme, Sidmouth, the wife of Leslie Price Harris, M.C., M.R.C.S., of Gerrards Cross and Harley-street, of a daughter.

Webb-Johnson.—On Sept. 5th, at East Sheen, the wife of Dr. Cecil Webb-Johnson, of a daughter.

MARRIAGES.

Pendered—Singer.—On Sept. 6th, at St. Peter's, Bedford, Captain J. H. Pendered, M.C., F.R.C.S., R.A.M.C., to Margaret Louise Singer, late Q.A.I.M.N.S., third daughter of Lieut.-Colonel G. H. and Mrs. Singer, of St. Augustine-road, Bedford.

Thompson—Seaton.—On Sept. 7th, at St. Michael's, Orchard Portman, Taunton, James Thompson, M.C., M.B., Ch.B., to Margaret Catherine, only daughter of the late Gervase Douglas Seaton and Mrs. Seaton, of Elmfield, Taunton.

Verney—Scott Reid.—At Holy Trinity Church, Karachi, on July 28th, 1921, Major Leonard Morris Verney, D.S.O., F.R.C.V.S., Royal Army Veterinary Corps, only son of Richard John Verney, of Oxford, to Sydney Jessie Scott Reid, M.R.C.S., L.R.C.P. Eng., elder daughter of the late Surgeon-General Sir Adam Scott Reid, K.C.B., Indian Medical Service.

DEATHS.

Callender.—On Sept. 5th, at St. Mary's Hospital, Paddington, after a short illness, Dr. Leonard Hay Callender, aged 50 years.

Freyer.—On Sept. 9th, at Harley-street, W., Colonel Sir Peter Johnston Freyer, K.C.B., late I.M.S., aged 69 years.

Trotter.—On Sept. 10th, at a Leeds nursing home, Robert Hale Trotter, M.D., in his forty-ninth year.

Wilson.—At 36, Greenfield-road, Colwyn Bay, on the 11th inst., George Wilson, M.D., LL.D., in his 84th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Correspondence.

"Audi alteram partem."

MAN'S EVOLUTION FROM THE ANTHROPOID.

To the Editor of The Lancet.

Sir,—I feel I must be only one among many of your readers who have found of exceptional interest Prof. L. Bolk's lecture on the Part Played by the Endocrine Glands in the Evolution of Man, which appears in your current issue. That the structural changes attendant upon animal evolution are in large measure brought about through the instrumentality of the endocrine system none can doubt. This system, as the professor observes, controls both ontogenesis and phylogenesis. Many human characteristics, such as orthognathy and hairlessness, he attributes to a suppression, brought about by the endocrine system, of anthropoid characters; and he further suggests that the retardation in the developmental rate of man, a condition essential to his high grade of evolution, may be due to the change in "the nature of his food, the frugivorous ancestor of man becoming omnivorous or carnivorous."

This latter surmise—as to the truth of which I am not prepared to offer an opinion—I find of peculiar interest, inasmuch as it accords with a view already put forward by me in this journal[1]—namely, that man's evolution from the anthropoid was determined by the search for animal food—the abandonment of the forest for a hunting career. I argued that the evolution of *homo sapiens* depended upon the difference in point of difficulty between plucking a sessile fruit and catching an elusive prey. Herein lies the key to the situation. I may, perhaps, be permitted to quote from the second of the two papers referred to.

"It was the conditions entailed by a hunting career which brought about the evolution of the pre-human ape into man. For observe the peculiar situation—assuredly one of the most eventful and dramatic in the whole of man's evolution—when this creature took to hunting. Here was a being lacking the stereotyped equipment for slaughter, instructive and anatomical, of the carnivora, but gifted with an intelligence surpassing that of any other creature, and endowed with prehensile hands capable of giving effect to that intelligence. It was a situation in which intelligence counted in the life-struggle as it had never counted before, and it inevitably led to the evolution of a higher type. This agile, intelligent, hand-endowed precursor of man was compelled to rely upon his intelligence in hunting his prey—to live by his wits: for blind instinct he had to substitute strategy; for natural weapons, weapons made by hand. Once the pre-human ape started on his career of hunter, he began a struggle in which it was inevitable that a higher and ever higher grade of intelligence should continue to evolve by natural selection until sufficient mental capacity had been attained to render its possessor supreme in the chase."

It is obvious that something must have happened in the case of the pre-human anthropoid, alone of all the anthropoids, which greatly increased the survival-value of intelligence. That something was the adoption of a hunting career by a highly intelligent prehensile mammal lacking the special hunting equipment of the carnivora.

It is conceivable that the adoption of a highly animalised diet may have facilitated man's evolution from the anthropoid in the manner suggested by Prof. Bolk; but that the initiation and maintenance of that evolution were due to the conditions necessitated by the procuring of animal food rather than to the effect of animal food upon the organism may, I think, be regarded as certain.

I am, Sir, yours faithfully,
Harry Campbell.
Wimpole-street, W., Sept. 11th, 1921.

THE SWIMMING-BATH AND CATARRHAL OTITIS.

To the Editor of The Lancet.

Sir,—In the annotation upon the above in your issue of Sept. 3rd, you state that Dr. K. Amersbach seems to have been discouraged from making any bacteriological examination by the fact that investigations of the kind undertaken by ophthalmologists on swimming-bath conjunctivitis had been inconclusive; and in his letter of Sept. 10th Dr. Dan McKenzie also deals with ear infection, stating that every effort should be made to render and to keep swimming-bath water as clear as possible. I should like to remind you that in September, 1909, in two somewhat lengthy reports, and in my annual report for the year 1909, I pointed out to the Baths and Washhouses Committee of the Poplar Borough Council the horrible dangers of the public swimming-baths, inter alia mentioning how quickly swimming-bath water changes its pristine sweetness even after being used only by a few bathers, particularly so in warm weather, and becomes after use by a number of bathers nothing more nor less than diluted sewage, and this condition exists often before the first day's use is finished. The formation of slime in the bath water was also mentioned and commented upon at length.

As it is during the months of July, August, and September that swimming-baths are mostly used, it would be of considerable interest if bacteriologists would take into consideration the possible connexion with disease of polluted swimming-bath water, more especially the slime which forms and settles at the bottom of the baths and becomes stirred up by the swimmers, and to find out if such slime plays any part in disease. I am sorry I cannot oblige with any of the slime from the Poplar swimming-baths, as they are kept free of it by the addition of electrolytic fluid manufactured by the Poplar Borough Council and added in the proportion of one part of chlorine to two million parts of the bath water. In swimming-baths a vegetable growth also occurs on the sides, but since the treating of the water in the Poplar baths such growth is absent.

I would also call Dr. McKenzie's attention to the "Report on Purification of the Water of Swimming Baths" by a Committee of the Royal Sanitary Institute, November, 1912 (excerpt from Vol. XXXIV., No. 1, 1913, of the *Journal of the Royal Sanitary Institute*).—I am, Sir, yours faithfully,

Fredk. Wm. Alexander,
Medical Officer of Health.
Bow-road, E., Sept. *10th*, 1921.

THE NATURAL HISTORY OF ENCEPHALITIS LETHARGICA.

To the Editor of The Lancet.

Sir,—Dr. H. Willoughby Gardner, in the important and interesting letter published in your columns this week, shows that, concerning the cases now called "encephalitis lethargica," he has arrived at certain conclusions which he shares with not a few physicians who, like him, have practised as consultants in wide and somewhat thinly populated country districts, and who have been able therefore to adopt the epidemiological point of view, or, in his own words, *to observe the natural history of diseases.*

Briefly, Dr. Gardner finds that the cases now referred to the fluctuating and arbitrary concept denoted by the term "encephalitis lethargica" should be considered as the nervous manifestations of a disease which is (1) very widespread, (2) markedly infectious, and (3) "new in character," whilst otherwise indicated by (*a*) fever, (*b*) sore-throat, (*c*) gastro-intestinal, and (*d*) bronchial catarrh, together with (*e*) an inconstant erythema, (*f*) marked prostration, and (*g*) slow recovery.

It was on precisely similar clinical and epidemiological observations that Fernel, Benedetto and others, in the sixteenth century, based their famous doctrines sources. To-day this sum is obtained in various ways, often at considerable monetary expense and by the employment of men and women who give their services voluntarily; no margin is afforded for the extension of hospitals, for more accommodation than exists to-day, or for new developments in the machinery for the cure of diseases; the amount is only enough to keep the hospitals going on their present basis. For these further objects money will be wanted; and it is time to enlist the support of the working class. During the past 50 years the status of the working man has undergone a profound change. At the beginning of this period he was rightly considered a poor man; he did not then earn enough to pay his weekly bills and leave a margin for contingencies. To-day he earns a good wage; he is supported during any sickness, and after 70 years of age is pensioned by the State. The working classes are now, I believe, in a position to say, "We can find it if you show us how and what benefit we shall obtain in return for our contributions." The following is an attempt to explain this benefit and the means by which it may be obtained.

Source of Revenue.

The present charity hospitals are, it is well known, more than adequate for the treatment of the really poor now that the working classes have risen from the lowest grade in society, and have acquired an independent and honourable position of their own. By coöperation they can, as I will show, share adequately with their employers in the maintenance of hospitals. There are about 13,000,000 men and women in our country who work for a weekly wage and are insured for definite purposes under the National Insurance Act. Moreover, under that Act is provided very economical machinery for the collection of contributions. If the same machinery were used any addition to the sum now collected by the Insurance Commissioners would involve a very slight and insignificant increase in the cost of collection. By a contribution of 1*d.* per week 13,000,000 men and women would provide £54,166 13*s.* 4*d.* weekly—that is, £3,066,666 13*s.* 4*d.* in one year. If to this is added 1*d.* per week by the employer from the industry for each employee twice the above sum would be available at the minimum cost of collection. This total of £6,133,333 6*s.* 8*d.*, together with the moneys now accruing from hospital charities, would amount to nearly £7,000,000 per annum, which sum the National Insurance Commissioners—the proper collecting body—would refund to each locality according to its needs. As the cost of the present hospitals is about £3,500,000 over and above that received from endowments the excess of money under the scheme could be put aside: (1) for the extension of existing hospitals; (2) for the re-erection of others in more suitable situations, or more commodious sites; and (3) for the establishment of new hospitals.

Consequential Changes.

The support of the hospitals by insured persons and by employers of labour, as above suggested, would be followed by many changes. The charity hospitals with their endowments would be absorbed by the new and reorganised institutions, and their mode of government would be modified to meet the new conditions. All service in them would, as a matter of course, cease to be merely voluntary. Apart from those who constitute the governing body, only the doctors at present render voluntary service. As, however, medical men are already appealing for payment for attention to sundry cases sent into the hospitals by public bodies, and are prepared to accept fees from payments made direct to the governing body by patients, the step I suggest is only a small one. Great advantages would, in the opinion of many, follow payment of the medical officers, as the time is at hand when work in the large hospitals should be undertaken only by those who devote their entire time to some specialty. Such work is too arduous and exacting for the man compelled to devote much time to other practice as a means of livelihood. The hospital doctor requires times for study, which, in the present condition of things, is very difficult to obtain; moreover, the medical student only receives such technical training in the methods for the discovery and for the curing of disease as will suffice to meet the requirements of examiners; newly qualified men, except in a very small proportion of cases, remain without opportunity to apply their book knowledge acquired with much labour and great expense. Again. the present system in the charity hospitals to which medical schools are not attached prevents the natural development of the machine for the proper treatment of patients; not until specialists only are employed can the work done in them be fully satisfactory. The recent progress of medicine and surgery makes it imperative for all specialists to have time for study and thought and to have their work apportioned and within their compass. The gain from this alteration would be immense if estimated only in the reduction of time an insured patient would take to become fit for the resumption of work.

Benefits.

But other benefits would be derived from a reorganisation of the hospital service on the new financial basis. Among them are relief of the home from the care of sickness and injuries, and a speeding up of the process of cure from immediate and proper attention and from the application of the appropriate means available in all large institutions but wanting in the home and seldom found in the smaller hospitals. In any scheme of reorganisation ample provision of beds must take precedence; a proper period of rest. combined with suitable employment, is essential to complete cure for the early resumption of work. To the injured workman the convalescent period is of extreme importance, and nowhere can this be ensured as fully as in graded hospital institutions designed for the purpose, arranged and equipped for the production of preliminary employment under healthful conditions. All dependants should be entitled to any advantages enjoyed by the heads of families; the houses of working men, necessarily of small size, would thus be relieved of all their sick and injured inhabitants greatly to the benefit of the rest of the family or occupants. Small-pox and other infectious diseases cannot be adequately isolated in such houses, which, moreover, are not large enough for maternity cases; it is therefore obvious that adequate provision for childbirth and after-care of mother and child would be necessary.

It will have to be recognised that the layman, however well acquainted with the business management of hospitals. is not the proper person to undertake the reorganisation of the hospital service. Such reorganisation must be the work of medical men who can grasp the problem as a whole. And those in charge of the finances should realise that it is not in the best interests of the patient that doctors should continue to render service on the old voluntary lines. We must break with the past, remodel the hospitals, and reorganise the professional work carried on in them, without losing sight of those sound fundamental principles under which the profession has won its present status. Whatever new hospital service might be devised the new conditions should embrace the following requirements: (1) The hospital medical service to come under the control of a sub-department, hospital service department, of the Ministry of Health; (2) appointments to be for life with the usual reservation as to behaviour, incompetency, &c.; (3) all payments on a whole-time basis; (4) promotion by merit combined with length of service; (5) translation, by direction of the sub-department of the Ministry of Health, as need arises for special services in different parts of the country.

The government of the hospitals would rest with the insured persons and employers; the State would represent the charities and thus exercise a measure of control. To ensure successful working the medical and surgical staff should hold office under a special body other than the governing body of the institution to which they are attached; otherwise the service would deteriorate, often very seriously, and in some instances would become almost worse than useless for reasons which need not here be stated.

Conclusion.

The scheme I have outlined is, I believe, the best available solution of the hospital problem confronting us to-day; I venture to think its adoption would lead to a quiet and very desirable revolution in the government, management, and usefulness of the hospitals. Money would be available for the development of matured and well thought out schemes and provisions of ample and immediate accommodation for sickness and injuries as soon as possible after their infliction. The result of speeding up the process of recovery would, I am satisfied, repay many times over the cost involved in the proper application of skilled doctoring, nursing, and convalescent training. Moreover, unification, in a general sense, of all hospitals and the creation of large institutions would lead to an economy impossible in the existing small and independent hospitals throughout the country. We need more for the money spent. and more cannot be obtained without reorganisation of the hospital service; from unification will result both economy in business management and better handling of disease and injury.

A CLINICAL THERMOMETER SHEATH.

Mr. A. E. James, head male nurse at St. John's Hill Infirmary, Battersea, has called our attention to the "James Thermometer Sheath" which he has devised. The sheath is a paper tube closed at one end, which is placed over the bulb and a portion of the stem of the clinical thermometer. When inserted into the patient's mouth the temperature is duly recorded, the thermometer withdrawn, and read. No cleansing is required, as the glass has not been in actual contact with the mouth. The sheath is ejected or removed by the patient. A further advantage is that, in the event for proficiency in midwifery and gynæcology. The Buchanan scholar is required to act for six months as resident physician in the university gynæcological wards of the Royal Infirmary, and this appointment was of great professional value to Helme, bringing with it also the formation of a lifelong friendship with his teacher, Sir Alexander Simpson. In 1886 he obtained the Leckie-Mactier Fellowship, and proceeded to Strasbourg, where he carried out researches in his own specialty, being awarded a gold medal for the thesis which he presented for his degree of M.D. in 1889. In 1890 he was elected Freeland Barbour Research Scholar

Dr. Helme began general practice in Fallowfield, Manchester, along with Mr. John Priestley, but found its pursuit not to his liking. On the advice of his friends he applied for and obtained the post of resident obstetric surgeon in St. Mary's Hospitals, an appointment usually held for three years, and one unrivalled in its opportunities of obtaining clinical experience in work of midwifery and gynæcology, being the nearest approach in this country to the much-coveted post of "interne" in the Paris hospitals. This meant severing his connexion with general practice, and a second spell of work as a resident physician in a hospital. The whole trend of Helme's work was towards midwifery and gynæcology, so that with his Edinburgh, Strasbourg, and Manchester experience in the theoretical, clinical, and practical aspects of these subjects he was well justified in becoming a consultant in Manchester at the end of his residentship. He was appointed shortly thereafter to the post of assistant gynæcologist to the Clinical (now the Northern) Hospital for Women and Children, and some years later, on the death of Dr. Samuel Buckley, he became honorary physician to that institution. Although never physically robust, and in spite of a measure of ill-health, Dr. Helme was soon well known as a specialist over all the North of England, where, as in Manchester and its neighbourhood, his services as a consultant were in constant request, so that during a busy professional life he rapidly acquired a large practice.

But his energies and activities were by no means confined to purely professional work. He did not write much, but what he wrote was of solid worth. Amongst publications were "Anatomy and Physiology of the Uterus, with Action of Drugs upon it" (Graduation Thesis, 1889). "Changes in Muscle Fibre, Connective Tissue and Blood-Vessels of Uterus during Pregnancy and Puerperium," "Aseptic and Antiseptic Methods in Midwifery," and "The Unborn Child: its Care and its Rights." For many years he was honorary secretary to the Manchester and Salford Sick Poor Nursing Institution, and was also vice-president of the North of England Obstetrical Society. He threw himself with great ardour into certain phases of medical politics, and was a useful member of the Council of the British Medical Association, while he acted as secretary and was for a period president of the Lancashire and Cheshire branch of the Association. His name came prominently before the public as a champion of certain medical interests, and he was a doughty opponent of the National Health Insurance Bill. The Edinburgh tradition of guarding the honour and dignity of his profession found expression in many phases of his professional activity. A friend of and sympathiser with the poor, his memory will be gratefully cherished in many homes in and around Manchester, where practically the whole of his professional life was spent.

Medical News.

VISIT OF DR. OSKAR FRANKL TO DUBLIN.—On the invitation of the Royal Academy of Medicine in Ireland three lectures have been delivered in Dublin during the past ten days by Dr. Oskar Frankl, the distinguished head of the Schauta Clinic in Vienna. The subjects chosen by Dr. Frankl were "Menstruation and Ovulation," "The Early Diagnosis of Uterine Cancer," and "Radium and X Ray Treatment in Gynæcology." As a teacher of unusual lucidity with an almost unrivalled experience, his lectures attracted large audiences. In addition to his set lectures to the Royal Academy, Dr. Frankl conducted daily classes in Trinity College and at the Coombe Hospital, both of which were well attended. Our Irish Correspondent, in chronicling the visit, writes: One may hope that the precedent set by Dr. Frankl's visit will not be forgotten. The Royal Academy would increase its prestige and put the medical profession of Ireland still further in its debt if it were to arrange at intervals for such a visit from some distinguished foreign teacher. The welcome given to Dr. Frankl by the Dublin School means more than merely what is due to a distinguished man of science. It is a sign of admiration for the magnificent work for humanity and knowledge performed by the Vienna School in the past, and of sympathy with the vitality which that School still exhibits amid circumstances of almost overwhelming difficulty.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—The introductory address of the winter session will be given in the board room of the hospital on Friday, Sept. 30th, at 4 P.M., by Dr. Adolphe Abrahams, on "The Advantages and Disadvantages of a Small Medical School."

DORSET COUNTY HOSPITAL, DORCHESTER.—The new pathological department and X ray and electrical rooms will be open to inspection on Wednesday, Sept. 21st, at 3.30 P.M., when Mr. James Sherren, surgeon to the London Hospital, will give an address on "The Value of Pathological and X Ray Examinations in Abdominal Surgery."

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL DINNER. The annual dinner will take place at the Imperial Restaurant, entrance in Glasshouse-street, London, W., on Saturday, Oct. 1st, at 6.30 for 7 P.M. The chair will be taken by Dr. H. A. Des Vœux. Tickets may be obtained from the hon. secretaries, Dr. Claude Frankau and Mr. J. A. Torrens, at the hospital.

SOCIETY FOR THE STUDY OF INEBRIETY.—The Ninth Norman Kerr Memorial Lecture will be delivered by Sir Arthur Newsholme on Tuesday, Oct. 11th, at 5.30 P.M., in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole-street, London, W. 1. The subject of the lecture is "Some International Aspects of Alcoholism with Special Reference to Prohibition in America."

SOCIETY OF M.O.H.'s.—The annual general meeting of the Navy, Army and R.A.F. Hygiene Group of the Society will be held at 1, Upper Montague-street, Russell-square, London, W.C. 1, on Friday, Sept. 30th, at 4.30 P.M., when Major-General Sir W. G. Macpherson will read a paper on "The Disposal of Latrine Contents, with Special Reference to Immediate Incineration." All members of the Society are invited to attend and take part in the discussion. Surg. Rear-Admiral Sir P. W. Bassett-Smith has been nominated to succeed Lieut.-Colonel H. R. Kenwood as President of the Group for the coming session.

CONFERENCE OF THE BRITISH COMMERCIAL GAS ASSOCIATION.—At the tenth annual conference of the Association to be held in the Royal Technical College, George-street, Glasgow, on Sept. 27th and 28th, the subjects to be discussed at the public sessions will be "Gas in Relation to Hygiene and Smoke Abatement" and "The Industrial Uses of Coal Gas." Dr. J. S. Owens, superintendent to the Advisory Committee on Atmospheric Pollution, will contribute to the former discussion a paper on "The Prevention of Smoke Pollution," and Dr. C. W. Saleeby will deliver a lecture on "Life and Light."

THE FARADAY SOCIETY.—A general discussion on Catalysis with Special Reference to Newer Theories of Chemical Action will be held at 4.30 P.M. on Wednesday, Sept. 28th, at the Institution of Electrical Engineers, Victoria Embankment, W.C. 2. Prof. J. Perrin (Paris) and Prof. Irving Langmuir will open the discussion, and among those contributing to it are Prof. E. C. C. Baly, Prof. F. G. Donnan, Prof. W. C. McC. Lewis, Prof. A. Lindemann, Prof. A. W. Porter, and Dr. E. K. Rideal. It is expected that Prof. Arrhenius and Prof. Victor Henri will also be present. Tickets of admission may be obtained from the Secretary of the Society, 10, Essex-street, London, W.C. 2.

MILESTONES IN ANÆSTHESIA.

I. In A.D. 1875 a student, just qualified, when he was dresser in the eye wards at Guy's, gave the deadly drug chloroform in a closed inhaler to a patient upon whom Higgens was to operate for cataract. He proceeded to do his part with the confidence of ignorance, and with absolutely no instruction except such as he had gathered from watching the house surgeons in the theatre. All went well, and only a little sickness followed.

II. In A.D. 1887 the same student, now sobered by practice, gave chloroform in a similar way for Lister to perform a serious operation. That great and kind man instructed him in the better method of placing as much of the corner of a stiff towel as would cover the patient's nose and mouth, telling him to keep that surface gently wetted the whole time, with excellent result. Only the usual, or "laudable," vomiting followed.

III. In A.D. 1921 the same man, spectator and no longer practitioner, witnessed the administration of ether to his wife for the extraction of a difficult tooth. The excellent young anæsthetist used a Clover, holding it an inch away from the mouth, and gradually bringing it closer until quiet induction was complete, prepared to give ether on a flannel mask if it were needed. All went well of course; no vomiting, discomfort, or danger occurred, and directly afterwards the patient was talking clearly.

Perhaps these advances in 46 years are worth noting.

SEPTUAGENARIAN M.D.

SANITATION IN BENGAL.

IN the fifty-second annual report on Sanitation in Bengal in 1919, recently issued, Dr. Charles A. Bentley, Sanitary Commissioner, states that the vital statistics are calculated on a population of 45,329,247, being that of the Presidency according to the census of 1911, excluding the Chittagong Hill Tracts. The birth-rate was 27·5 per 1000, compared with 32·9 in 1918, and 33·3 in the quinquennium (1914–18); it was the lowest recorded since 1892, due to unfavourable economic conditions resulting from the poor harvest of 1918, and a serious prevalence of influenza, with excessive mortality, during the latter half of that year and the earlier months of 1919. In the various districts it ranged from 18·5 in Calcutta and 21·0 in Jessore to 32·8 in Rajshahi and in Noakhali. With regard to the rates in towns, it is stated that the "abnormally low birth-rates are due solely to neglect to register the births that actually occur." Presumably the same observation might apply to rural areas, of which 37 returned birth-rates below 20 per 1000; but this explanation would be at variance with the attribution of a low birth-rate to a poor harvest and influenza.

The general death-rate was 36·2 per 1000, compared with 38·1 in 1918 and 31·2 in the preceding quinquennium. Of the total number of deaths (1,641,111), no less than 1,229,257 are returned under the head of "fevers" (27·1 per 1000); this mortality was specially heavy during the first six months of the year, and was undoubtedly due to influenza; in the latter part of 1918 some 350,000 to 400,000 deaths may be ascribed to this cause, and in 1919 a further 200,000; Birbhum and Burdwan districts suffered most, with a probable loss of about 3 per cent. of their population during the last two years.

An Epidemic of Cholera.

Cholera was epidemic throughout the province—namely, in 491 out of 498 registration areas. The deaths reported (121,910) were in a ratio of 2·8 per 1000, compared with 1·8 in the preceding quinquennium. Only once in the last ten years has this ratio been exceeded. In the district of Birbhum the ratio was 6·8, and in that of the 24 Parganas 5·9, where the deaths from this cause numbered 14,360, this being the largest number reported from any individual registration area. Dr. Bentley remarks that "the October rainfall of 1918, on which the normal outturn of the winter rice crop depends, was much smaller than usual. The early cessation of the rains which occurred, especially in the Burdwan and Presidency divisions, reduced the supply of water available during the succeeding months. The deficient rainfall and short harvest also led to increased migration. Thus the factors necessary for the occurrence of widespread epidemics of cholera in 1919 were provided by the unfavourable season of 1918, with the results that have been recorded." The outbreak among pilgrims returning to Calcutta from the native festival on the island of Sagar at the mouth of the Ganges, when a large number of cases of cholera were landed in the city (Dr. Bentley states the number to have been "some 217"), and the energetic and successful manner in which this emergency (to which the epithet "appalling" may be fitly applied) was dealt with, have been already alluded to in these columns.[1] Dr. Bentley considers that a considerable proportion of the excess cholera mortality in the succeeding months was indirectly due to infection originally brought from Sagar island. In several instances during the year outbreaks in the province were traced to polluted water, but increasing use is being made of permanganate of potash and chloride of lime for disinfecting wells and tanks.

Small-pox, Plague, Rabies.

There was a great increase in small-pox, the deaths numbering 37,010 in 1919, giving a ratio of 0·8 per 1000, compared with 0·2 in 1918 and 0·3 in the quinquennium, 1914–18; the vaccinations increased from 1,619,280 in 1918 to 2,216,812 (if the figures are to be relied on, which Dr. Bentley considers to be doubtful). The deaths from plague numbered 424 (0·01 per 1000); 334 of these deaths occurred in Calcutta (0·4 per 1000). There were 179 deaths from rabies during 1919, compared with 119 in 1918 and 71 in 1917; the increased mortality emphasises the need for a Pasteur Institute (at Calcutta), more accessible than those at Kasauli and Shillong.

The work falling upon the Sanitary Commissioner has greatly increased in recent years, and a special committee is considering the matter with a view to improved organisation. It may be noted that the population of Bengal is approximately the same as that of the United Kingdom.

---

[1] THE LANCET, 1921, i., 307.

INDIAN JAIL OCCUPATION.

IN the Administration Report of the Jails of the Bengal Presidency for 1920 Lieut.-Colonel F. S. C. Thompson, I.M.S., the inspector-general of prisons for the Presidency, gives an interesting note on the diet of prisoners. The proportion of prisoners voluntarily choosing wheat at one meal in lieu of rice is steadily increasing. The beneficial result of this nutritious diet is evident from the fact that cases of bowel complaints have gone down considerably, and of the 32,175 convicts discharged during the year 54 per cent. gained weight, while only 19 per cent. lost weight. The daily average strength for the year was 15,357, the number admitted to hospital 20,254, and the daily average number of sick 812, against 15,886, 22,699, and 878 respectively in the previous year. The total number of deaths during the year was 321, against 365 in 1919. The commonest cause of mortality at the two most unhealthy jails, Malda (death-rate 78·8) and Jalpaiguri (69·2), was malaria, while dysentery proved the main reason at the next two jails, Burdwan and Faridpur, although malaria remained the chief cause of sickness. The industries pursued by the prisoners in the various jails include the manufacture of jute, iron goods, the printing and supply of forms, the manufacture of cloths and blankets, and of lubricating and medicinal castor oil and of mustard oil. In the juvenile jail the most important industry is the manufacture of quinine tablets. On an average 83 boys were employed on this industry and 13,195 lb. of quinine sulphate were converted into treatments and tablets during the year. 1,074,321 treatment tubes (each containing 20 four-grain tablets), 712,520 five-grain tablets, and 50,875 two-grain tablets were sold during the year. This jail also acts as a distributor of cinchona products. The total profits of the jail from the quinine industry and other manufactures amounted to Rs.233,561, against Rs.230,022 in the previous year.

THE HOSPITAL PROBLEM AND A NEW HOSPITAL SERVICE.

BY JOSEPH GRIFFITHS, C.M.G., M.CH. CAMB., F.R.C.S. ENG.,
SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

IT must be clearly understood that every attempt to place hospitals for the sick and injured on the rates under the Poor-laws has failed, and a new attempt is no more likely to succeed to-day than those made in the last century, even if the authority be changed to the County Council. Hospitals of large size, and more of them, are the greatest social need of the day; as the hospitals constitute the hub of the medical world, it is best to re-establish them on a sound and satisfactory basis so as to be able to build up and add spokes and a rim that will make a solid, substantial, and complete wheel of medical organisation with the general practitioner at every point in the periphery and the highly-trained specialist in the centre—each doctor a specialist in his own sphere, with every facility to pass the patients back and fore as conditions dictate, the whole being arranged and connected for the sole benefit of the sick and injured.

From small beginnings the hospital service in this country has gradually become very complex, and few are familiar with its many phases or understand how it is made up. It was created by charity, and not until 1810 was much done to relieve charity of a burden that had then become too heavy; in that year were passed the Poor Law Amendment Acts of Queen Victoria. Since that date the guardians have made provision—adequate in places, inadequate in others—for the care of the sick and indigent poor. In 1818 the first Public Health Act made provision under the Local Government Board for the isolation and treatment of infectious diseases, and thus to some extent relieved the charity hospitals. To-day we have charity hospitals, Poor-law infirmaries, public infectious diseases hospitals, &c.; the first governed by supporters of charity, the last two by public authorities, the guardians and the local public health body respectively. The provision made by the Poor Law Amendment Act and by the Public Health Acts far exceeds that supplied by charity.

The charity hospitals are divisible into two large groups—those with medical schools, and those without medical schools.

The Charity Hospital Medical Schools.

In this country medical education, begun in charity institutions, has been maintained in them by the help of generous friends—not from the funds of the charity—and by the great efforts and self-sacrifice of the medical teachers for centuries past. During the nineteenth century the Government gave help in some directions, and the Education Department is to-day experimenting with medical education in the hope of placing it on sounder footing, but there is doubt whether the experiment will serve its intended purpose. The hospitals in which medical education has been fostered are chiefly the large ones in London. It may be of interest to group these hospitals in accordance with the periods in which they were founded. In the twelfth century, St. Bartholomew's; in the sixteenth, St. Thomas's; in the eighteenth, Westminster, Guy's, St. George's, the London, and the Middlesex; and in the nineteenth, Charing Cross, King's College, University College, St. Mary's, and the Royal Free. All were and are dependent for their income on charitable contributions and bequests, and their resources have been well spent and carefully husbanded for the benefit of the sick poor—and, of late years, of those who, whilst not to be classed as poor, but who were totally unable to afford the expense of nursing and of skilled attention from a physician or surgeon. In return for medical services, hitherto given free, the governors of the charities have granted the medical officers the privilege of creating medical schools within the precincts of the charities and the use of the hospital wards for the training of students. It is not too much to say that the success of these great hospitals is largely due to that intimate association of the school with the hospital, which has acted as an intellectual stimulus to the hospital staffs. Medical education has not been subsidised, as has every other form of education, largely because medical men have been content with indirect rewards; and the latter are apt to be very unequally distributed. Most of us think of St. Bartholomew's and the other big hospitals in London first as medical schools, and secondly as hospitals, although they are maintained primarily for a hospital service for poor people. The need for such special fostering of medical education was so strongly impressed upon the teachers in the early Victorian days that it was held by them that the establishment under the suggested Poor-law Bills of large London hospitals alongside the charity hospitals to which were attached medical schools, would practically cripple the British system of medical education. Indeed the collective action of these teachers actually prevented the development of a new hospital service that, in the opinion of many, would have grown in the remaining portion of the nineteenth century into a magnificent organisation, providing not only London but also the rest of the country with adequate accommodation for the sick and injured.

Charity Hospitals Without Medical Schools.

In 1810 it was fully recognised that the support of charity was inadequate for the growing needs of hospital service; and from that date onwards the disparity between the supply of accommodation and the demand for it has steadily increased. Between 1860 and 1870 London was in dire need of additional hospital service, but the expense could not be faced. Before the war, in spite of the growth of existing hospitals, the creation of many small ones, and of innumerable cottage hospitals, the deficiency of provision was very evident. During the war attention was diverted from this question, but the public was educated, by force of circumstance, in the value of hospitals, by witnessing the rapid and successful treatment of injury and disease. The result is an appreciation on their part of the need for more accommodation to meet the increase in population.

If the resources of charity had begun to fail in 1810 and have not since been able to meet many of the demands made upon them, as is well known to the Poor-law and public health authorities, provision from that source is most unlikely to be forthcoming for the additions now contemplated. The Royal Commission in its recent report recommends a subsidy of £1,000,000 to clear some of the hospitals of debt, and further suggests a new mechanism for the collection of funds, but the Commissioners show no appreciation of the pressing need that exists for extension of our present hospitals and for the erection of new ones, nor do they differentiate between the great charity hospitals containing medical schools and those hospitals unhampered by the machinery of education. Hospitals with medical schools attached are exceptionally placed; upon them the entire fabric of medical education rests. They are entitled, therefore, to those privileges which all other educational institutions now enjoy in the matter of State support. The charity hospitals in London and throughout the country, used solely for the purpose of affording relief to the sick and injured, need no special consideration. When these institutions were founded the working classes were included amongst the poor. To-day they are as well off as, if not relatively better off, when in employment, than, any other class in the community, and it can scarcely be maintained that they require the help of charity to provide a medical service for them and their dependents. The guardians may to-day, as ever since the passing of the Poor Law Amendment Acts, make suitable provision for those few who are indigent in Poor-law or charity hospitals, being empowered to incur the necessary expenditure on their behalf. The hospital service of to-day is therefore kept up for the benefit of working classes, which everybody must rejoice to know are now in a position to provide a hospital service the like of which the world has never yet seen. These workers create industry, and the profits of industry are unobtainable without their help; they may justly claim that this service, perhaps the most essential for their welfare, shall be placed on a sound basis, and be supported in part by the industries they make a success.

The problems for immediate solution are: (1) the placing of the medical schools and their hospitals on a sound footing, and (2) the extension and modification of the existing hospital service to meet the needs of the working classes.

I do not propose to deal with the medical schools, for sooner or later the State, through the Education Department, must step in and place them in a position worthy of this country and of the magnificent system of medical education built up by and in great part at the expense of the teachers.

Hospitals for the Working Classes.

The first essential to the establishment of an extended hospital service is additional revenue. There is, of course, the money left in the name of charity, which the new hospitals would be entitled to claim, for the reason already given that the working classes until recent years were considered to be a poor and deserving section of the community. This money does not, perhaps, amount to more than £750,000 per annum for England and Wales. As the present cost of running our charity hospitals is over £1,000,000 per annum, nearly £3,500,000 would have to be provided from other subject who is not trying may give very discrepant readings. With the manometer again turned away, he may, by encouragement, be made to surpass his previous efforts, but when, after trying again whilst looking at the manometer scale, he will, if he is not really trying, not surpass the previous effort which he saw.

4. *Sustaining* 40 *mm. Hg* (*endurance or fatigue test*).—This test is performed as follows: the candidate is asked to empty the lungs, fill up, blow the mercury to the height of 40 mm. and hold it there without breathing for as long as possible, the nose being clipped. An essential adjunct to this test is the behaviour of the pulse, which is counted for every five seconds during the time that the mercury is sustained. As in the breath-holding test, the demeanour of the subject, the discomfort endured, and the resolution displayed are noted.

Before passing to a consideration of the results obtained it is necessary to consider each test in more detail and, if possible, to meet certain criticisms which may be made. As already indicated, the prime idea of such tests is to provide adjuncts to the clinical examination and not to carry out experiments of absolute accuracy with elaborate scientific apparatus requiring a difficult technique.

Vital Capacity.

The employment of a modified gas meter is open to the criticism that it opposes a resistance to the breathing out and gives inconstant readings. The resistance of a meter of good make is not large, but it is true that it is difficult to obtain a dry meter which gives accurate readings; the error to a steady rate of breathing out can be obtained by periodic testing. Mosso was apparently the first to use such an instrument in preference to the spirometer designed by John Hutchinson[2] and modified by various subsequent observers. Since the pioneer work of Hutchinson, much as been written as to the clinical value of the measurement of the vital capacity. One of the severest criticisms as to its value has been the great difficulty experienced by various observers in laying down what is to be regarded as the normal for any one individual. It is probably on this account that spirometry has not come into more general use. During the years (1846–1855) following the pioneer work of John Hutchinson, there was much work done upon the vital capacity of both males and females, and considerable discussion arose as to what factors should be taken into account in determining the normal standard. The literature for this period is given by Arnold.[3]

John Hutchinson considered the standing height as the principal factor determining the vital capacity, and worked out values based mainly upon this measurement. He found that the sitting height was of little value for this purpose. He considered that the vital capacity was also influenced by weight in relation to height, and also by the degree of mobility of the chest. He did not find any direct relationship between the circumference of the chest and the vital capacity. He states that the vital capacity is influenced by the bodily position in which it is taken, chiefly through altered mobility of the ribs, being greater standing than sitting; sitting than lying. It is influenced by age, increasing up to 35 and then decreasing to 65, and by sex, being greater in males than females. The taking of food modifies the vital capacity. Hutchinson found that the vital capacity varied with the occupation of the individual, being greatest in seafaring folk and military recruits, medium in police and firemen, low in sedentary workers.

Simon (1818) made observations upon the vital capacity. He set his standards by the standing height and gave figures which were somewhat smaller than Hutchinson's. He also made observations upon the influence of sex, but no observations on the effect of weight or age. He found that the capacity was influenced by the mobility of the chest as measured by upper chest expansion.

Fabius (1853) from his observations came to the conclusion that the standards for vital capacity could best be calculated from the sitting height and chest circumference. He found also that the mobility of the chest and the age of the individual had to be considered. He formed the opinion that a good deal depended upon the muscularity of the individual, the vital capacity being greatest in strong individuals, since they can breathe in and out more than weak men. He believed that the taking of food and constipation considerably diminished the capacity. He states that the administration of one ounce of lenitive electuary increased the vital capacity of his assistant by 250 c.cm. He found that the vital capacity was not decreased by pregnancy.

Wintrich (1854) made observations on 3500 healthy individuals, including 500 women, ranging from 6 to 90 years of age. He fixed his standards by the standing height, age, and sex. He found that consideration of the weight was of no practical value. He noticed also that in strong people the effect of bodily position was slight, but was striking in weak people. He found no effect on vital capacity as the result of pregnancy.

Schneevogt (1854) examined 300 healthy and diseased individuals particularly as regards the relationship between vital capacity and standing height, sex, and age.

Arnold (1855) reviewed the whole position and made many further observations upon his own account. He came to the conclusion that the vital capacity increases with the standing height. He could not agree that the measurement of the sitting height was of greater value than that of the standing height. He considered that the measurement of the chest circumference is one of value, particularly if a reduction of 5 cm. to 10 cm. be made for fat subjects and an addition of 5 cm. be made for thin ones. Weight was to be considered only in so far as it was influenced by height. He found a lessened capacity of 100–200 c.cm. after meals. He did not attribute importance to the degree of upper chest movement, believing that chest movement increases with height rather than with chest circumference. He therefore made different allowance for expansion at various heights. Age had a definite effect, but he found that the true value of age influence could not be sufficiently accurately determined. Arnold worked out figures for women; finding the vital capacity absolutely and relatively smaller than in man, he also found the measurement of chest circumference of less value than in man. He found no diminution as the result of pregnancy.

Despite Hutchinson's and Arnold's work spirometry did not come into general use—probably, as has been indicated, owing to the fact that it was found difficult to lay down an exact standard for an individual. From time to time observations of various authors have been published, but no attempt will be made to deal with such observations here.

In more recent years Bohr[4] has shown that the residual air of the lungs is increased during muscular exercise and that the vital capacity is correspondingly decreased—giving, as it is termed, a greater mid-capacity between the breaths. This is probably to allow more efficient circulation through the more distended lung during the period of exercise. On the other hand, it is obvious that the residual air cannot be increased above a certain amount without seriously affecting the efficiency of lung ventilation.

More recently Peabody and Wentworth[5] have again graded healthy individuals, both male and female, according to height. They give the figures shown below.

	Height.	Vital capacity.
Males	6′ and over 5′ 8½″ to 6′ 5′ 3″ to 5′ 8½″	5100 4800 4000
Females.. ..	5′ 6″ and over 5′ 4″ to 5′ 6″ 5′ 4″ or less	3275 3050 2825

They also show that the vital capacity is a function of the surface area, as calculated by Du Bois's formula.[6]

Dreyer (1919)[7] has applied the measurement of the vital capacity to the assessment of physical fitness. He finds the older methods of estimating the vital capacity inadequate, since they were based on the theory that definite relationships exist between age, height and weight, relationships which he believes do not exist. He publishes tables of the vital capacity based upon calculations from definite relationships which he shows to exist between the weight of the body, the sitting height, and the chest circumference. Full details are to be found in his recently published book on this subject.[8]

Vital Capacity during Disease.—In regard to the vital capacity during disease, Hutchinson pointed out the value of measurement in phthisis. He divided his cases into two classes, early and late. In the early stages he looked upon a diminution of 16 per cent. as suspicious, believing that unless the person examined was excessively fat he was probably the subject of disease. In late cases the deficiency may well amount to 2000 c.cm. or more. Various observers[3] (1846–1855) confirmed the value of spirometry in this respect (Simon, Fabius, Wintrich, Arnold, &c.). Wintrich believed that phthisis could be ruled out if the vital capacity was only diminished by 1/6, but believed that a positive diagnosis even without other signs could be made with a diminution of 1/5–1/4 the normal vital capacity. Arnold believed spirometry was of value not only in diagnosis but also in of accidental breakage of the thermometer in the mouth, the sheath will hold. There is nothing deleterious in the sheath, as rice paper, gum arabic, and paraffin wax only enter into its composition. Obviously the sheath must materially retard the correct recording of the temperature. Thus we found that an unprotected thermometer registered a rise in temperature from 73° to 100° F. in 18 seconds, the same instrument under similar conditions, but covered with a sheath, requiring 60 seconds. The inventor thinks the sheath should be found very useful to the busy physician passing from house to house during an epidemic. It would, however, be necessary first to determine that the retarded reading has no practical drawback.

UNIVERSITY TRAINING FOR WELFARE WORKERS.

THE Joint University Council for Social Studies, of which the object is the coördination and development of the work of university departments of social study, has issued its fourth report, entitled "*University Training for Welfare Work in Industry and Commerce.*" Since the publication of the Council's report on welfare training in 1917 much experience has been gained on the subject, and in January, 1921, a committee was appointed further to consider the subject and prepare a revised report. The committee consisted of members of the Council and of other persons of special knowledge and experience; representatives were appointed to it from the Factory Department of the Home Office, the Ministry of Labour, Employers, Labour, the Welfare Workers' Institute, and the Industrial Welfare Society. Owing to the illness of Prof. E. J. Urwick, chairman of the Joint University Council, Prof. F. Tillyard (Birmingham) was appointed chairman of the committee.

In the introductory section of the report the development of industrial welfare work is traced from its beginning at the end of the nineteenth century to its present position. Its definition in the Home Office pamphlet of 1919 is quoted as follows in the section devoted to the scope of welfare work in the report: "the provision by the management for the workers of the best conditions of employment . . . . including everything which bears on the health, safety, and general well-being and efficiency of the worker, while avoiding any interference with his private affairs." It is pointed out that the minimum requirements of various Acts of Parliament constitute the basis of welfare work, but its logical development includes canteens, recreational and educational schemes, medical departments, employment departments, thrift societies, &c. An essential for the success of welfare supervision is the confidence and support of the workers.

The summary of recommendations is briefly as follows: 1. Training for welfare workers should be provided by the Universities. 2. While no fixed standard of qualifications for training for candidates for welfare work can be laid down, it is essential that candidates should have had such previous education as to enable them to profit by the social study course. 3. Graduates desiring to qualify for welfare work should supplement their degree courses by specialised post-graduate study. 4. No definite age can be fixed for commencing welfare training, but a certain degree of maturity of thought and experience is essential. 5. While the length of training differs according to the previous qualifications of the student, two years is, as a rule, the shortest period necessary to cover both the academic training and the supervised practical work. 6. Candidates for welfare training should receive the customary training for social workers, with certain options in the second year. 7. The syllabus should include some treatment of the following subjects: industrial and social history, economics, social and political philosophy, health and hygiene, psychology, outlines of central and local government, elementary statistics, industrial law, business organisation, industrial structure and problems. 8. Students should have lectures and personal tuition by persons who have had welfare experience. 9. While regular work in a well-organised welfare department for an extended period forms an essential part of practical training, all students should have opportunities of practical experience which will give them an insight into the working of the public and social agencies of a modern community, and opportunities of association with normal conditions of working-class life. 10. Scientific study of the problems of industrial welfare being still in its infancy, facilities for advanced study of such subjects as industrial organisation, psychology, statistics, &c., should be provided at convenient hours with a moderate fee. 11. Students who satisfy the examiners in theoretical and practical work should receive the usual Social Study certificate or diploma, with a special endorsement as regards welfare work. 12. Bursaries should be provided in order that candidates without means should not be excluded from qualifying for welfare work.

The final recommendation is for the establishment of joint advisory councils composed of representatives of both employers and workers, as well as of welfare societies, in connexion with each university.

GAS DISEASE IN FISH.

THE great mortality, due to various causes, frequently caused in very hot summers in fish-breeding establishments is well known, and the mortality among fish from want of oxygen is very common in summer. It appears, however, that super-saturation of the water with oxygen may be a danger to fish life. The *Fishing Gazette* for August 27th directs attention to a condition occurring in fishes known in German as Gaskrankheit der Fische, and described by Prof. Marianne Plehn, of the Biological Experimental Institute of Munich. In ponds rich in plant life, especially those that contain a large amount of algæ, at times there is an enormous liberation of oxygen and the water becomes super-saturated therewith. A slight super-saturation is harmless to fish, but when it becomes considerable they suffer. More oxygen is taken up by the blood, and if a rise of temperature takes place the oxygen separates from the blood in the form of small bubbles, which may injure the gill vessels or may collect in the heart and so form a "gas embolism," which may cause death almost immediately. The gas bubbles may occur in the peripheral cutaneous blood-vessels and are easily seen in the fins; larger bubbles collect in the vessels of the head, in the mucous membrane by the mouth below the eyes, and with preference in the orbital cavities, so that the eyes may be made to protrude. If the fish is removed to cooler water the phenomenon disappears and it may quite recover. But if the blood is super-saturated with oxygen a fatal gas embolism may occur if the temperature rises. These observations seem to explain a phenomenon, noted by fish breeders, that a rich growth of algæ is injurious to the fry, and it is not improbable that the trouble is caused by an excess of oxygen. Other gases than oxygen may be absorbed from the water and be set free in the blood stream when the temperature rises or the pressure falls. Everyone is familiar with the discharge of nitrogen in the form of bubbles that may occur in too rapid decompression of a person who has been working in a caisson, sometimes with very serious or even with fatal results from gas emboli. Fish in water super-saturated with ordinary air under high pressure show the gas disease, but the gas bubbles liberated are chiefly nitrogen, which, however, are equally dangerous to life.

THE USE OF X RAYS IN OBSTETRICS.

ATTENTION was drawn in a recent issue of THE LANCET to the possible uses of X rays in ascertaining the position of the fœtus during pregnancy. An article in the August number of the *American Journal of Clinical Medicine*[1] exposes a further use of X rays in obstetrics—namely, in determining the various pelvic measurements with precision and without any inconvenience to the patient. The principle upon which this method depends is of course that the height of any object may be determined by a comparison of its shadow with that of another object of known length. The article cited consists of an illustrated description of the *technique*.

THE "BLACK PERIL" IN U.S.A.

STATISTICS of the Metropolitan Life Insurance Co. of New York show that the coloured population of the United States increased at a lesser rate during the last decade than ever before. The increase was in fact only 6·5 per cent. during the last ten years. While the birth-rate has remained stationary or thereabouts, the death-rate has been rising and has in some areas even doubled. The death-rate from tuberculosis among adolescent negro boys and girls is ten times as high as among whites of the same ages. Malaria, typhoid, and hookworm infection take a high toll in the Southern States, while syphilis does enormous damage among the coloured people. Among negro males between the ages of 15 and 35 years the homicide rate is approximately ten times that of whites.

A SIMPLE METHOD OF FIXING FINGER-PRINTS.

To the second (Sept.) issue of *Dactylography*, a bi-monthly journal, edited by Dr. Henry Faulds, dealing with identification by finger-prints, Mr. Leslie D. White has contributed an easy method of making finger-prints which he accidentally discovered while experimenting in photography. Expose a piece of self-toning printing-out-paper to the daylight until it becomes almost black, impress the finger on it for three seconds, and immerse the paper in a solution of potassium permanganate, when immediately the finger-print shows up black on a white background. Wash in water for two seconds, place in the usual hyposulphite of soda solution for half a minute, wash in water, and hang up to dry. The result is clear and permanent, and bears magnification. Mr. White claims as an advantage that the method does not soil the fingers, and there is no ink to clog the skin markings. Dr. Faulds adds a remark that the impressions look as if they would enlarge well for legal exhibits.

* After concussion in motor accident.

In addition to the measurement of the vital capacity, therefore, I prefer also to use in conjunction tests such as the breath-holding and 40 mm. Hg test, in which the performance of the individual depends upon the amount of the air contained within the lungs (vital capacity + residual air). It is to be anticipated that when the vital capacity is small and the residual air increased the performance will be poor, and conversely, when the vital capacity is large and the residual air minimal the performance will be good; I believe the above-mentioned tests prove this to be the case.

The Breath-holding Test.

The idea underlying this test primarily was that it would serve to give an idea of the subject's susceptibility to unpleasant sensations as the result of diminution of the oxygen-tension in the alveolar air. It was shown by Leonard Hill and the writer [14] that if a subject be asked to hold his breath, not knowing whether he has filled his lungs with air or with oxygen, the breath is held about two to two and a half times as long when oxygen is breathed in, as compared with the result when the lungs are filled with air. It was argued, therefore, that a man who could hold his breath long, until the alveolar oxygen-content was low, would probably be able to endure more easily the diminished oxygen-tension of high altitudes than one who more quickly suffered discomfort as the oxygen-tension was reduced.

By analysis of samples of the alveolar air taken by Haldane and Priestley's method at the beginning and at the end of the test it was found that certain subjects (found unfit) manifested signs of great discomfort with considerably less diminution of oxygen than did others who were fit. This is seen in the figures given in Table I., which are examples taken from observations made on 47 subjects. It was found that unfit subjects could not expire so forcibly as fit, and therefore that the true alveolar content might not be obtained, especially in taking the sample immediately after holding the breath. That there is such an increased susceptibility, however, especially to diminution of oxygen, was confirmed by observations made by breathing in and out of a five-litre bag, the carbon dioxide being absorbed. It was found that some subjects suffered discomfort when the oxygen percentage in the bag was reduced only to about 12 to 13 per cent., whereas others did not suffer until the oxygen percentage was reduced to 7 or 8 per cent. By calculation from this percentage a rough estimate of the height at which discomfort would supervene could be ascertained. For example, taking 16 per cent. as the oxygen-content of normal alveolar air at 760 mm. then a bag content of 11·5 per cent. corresponded to $\frac{760 \times 11\cdot5}{16} = 546$ mm. Hg = 9000 feet approximately as compared with a bag content of 8 per cent. which equalled 380 mm. Hg, or approximately 19,000 feet. It was found that this method provided useful information as to the height at which symptoms would develop and that it correlated well with the breath-holding test.

As already stated, the nature of the answer returned during the breath-holding test is important, the normal individual does not suffer from unpleasant sensations such as dizziness, giddiness, or nausea. The man unfit for flying was frequently found to be able to hold his breath but a short time and to give an abnormal answer as shown in Table II. As the result of experiment on successful officers chosen by

The Milroy Lectures

ON

RESPIRATORY EFFICIENCY IN RELATION TO HEALTH AND DISEASE.

Delivered before the Royal College of Physicians of London

BY MARTIN FLACK, C.B.E., M.B., B.CH. OXON.,
WING COMMANDER, ROYAL AIR FORCE MEDICAL SERVICE.

LECTURE II.*

THE evidence I have to offer as to the importance of the respiratory efficiency of the individual is based upon results obtained upon flying officers. Modern service flying, particularly in time of war, imposes a great stress upon the airman; it became important, therefore, to devise simple tests which besides helping to elucidate the causes of flying strain, would aid in the efficient selection of suitable candidates for flying. Various considerations soon led me to the point of view that in many cases of flying strain the first breakdown in the bodily system was probably in connexion with the respiratory mechanism, which became defective in working, reacted unfavourably upon the efficiency of the circulatory and nervous systems, and thereby brought out signs of cardio-vascular or nervous debility. To test this point an examination was made of the respiratory systems of successful pilots (chosen by the executive), of pilots in need of rest but not of medical treatment, and of pilots broken down by stress and requiring medical attention.

NATURE AND VALUE OF THE TESTS EMPLOYED.

It is not proposed to give here the full results of such examinations, many of which have been reported elsewhere.[1] Rather will be given illustrative examples to show the value of the tests employed. In regard to the final form which these tests have taken, it is pointed out that they were designed to act as adjuncts to the clinical examination and therefore had to be of a simple character, to require but little apparatus, and to be capable of easy application. It is further pointed out that the success of the use of such tests depends upon the exactness with which the technique is carried out; otherwise results of but little comparative value are obtained. In the first place were measured the vital capacity and the power to hold the breath after full inspiration and full expiration. At the same time investigations were made on the tidal air, on the composition of the alveolar air before and after holding the breath, and on the susceptibility of the subject to diminution of oxygen-tension by letting him breathe in and out of a five-litre bag, the carbon dioxide being absorbed. With further work the importance of efficient expiratory capacity was indicated by a number of observations, as, for example, by the fact that pilots suffering from strain could not blow round rapidly the dial-hand of the modified gas-meter employed for measuring the vital capacity; although this instrument offered but little resistance, the endeavour made such subjects flushed and out of breath.

In consequence the test for expiratory force was devised. For a time observations were also made on the power to draw up mercury by an inspiratory movement—but these were early found to be of little value, and were abandoned, since it was difficult to rule out the "sucking power" of the individual as distinct from "inspiratory force." Later the supplemental air was determined by asking the subject to breathe in quietly and out quietly as in normal respiration, and then to blow his reserve of air through the meter. The complemental air was determined by a reverse process—namely, after a quiet inspiration the sucking in of as much air as possible through the meter. Owing, however, to the difficulty of cleansing the tubes, &c., the determination of the complemental air was abandoned as unhygienic. It was found, however, that unlike the supplemental air, the complemental air was not affected, except possibly in one case of extreme fatigue.

SPECIAL ROUTINE TESTS.

Measurement was also made of the time during which the subject could, after full expiration and full inspiration, sustain a column of mercury at 40 mm. with the breath held and nose clipped, the pulse being counted during the process. By a comparison of the results obtained the following tests came into routine use in the Royal Air Force, as affording information of value: (1) Vital capacity; (2) holding the breath; (3) expiratory force; and (4) sustaining 40 mm. mercury (endurance or fatigue test).

These tests were employed in conjunction with tests for circulatory efficiency and nervous stability. For the former were employed: (1) The pulse-rate sitting, after standing up, and after regulated exercise (lifting the body-weight on to a chair five times in 15 seconds), and (2) measurement of the systolic and diastolic arterial pressures. For the latter were employed the tests introduced by Mr. Arthur Cheatle: (1) Observation of knee-jerks and other reflexes; (2) observation of presence or absence of tremor of eyelids, tongue, and fingers; (3) observation of the ability of the subject to stand steadily on one leg for 15 seconds with eyes closed and hands to side; and (4) the ability of the subject to raise from table to shoulder level and replace again an unstable rod placed on a piece of board.

The technique laid down for the special tests referred to above is as follows:—

1. *Vital Capacity.*—The candidate sits opposite the spirometer, the dial being so placed that he cannot see the readings. Neck, chest, and abdomen must move freely. With the nose clipped he is directed to fill his lungs to their maximum capacity, and then to expire as completely as possible at a fair rate through the meter. Several mouth-pieces must be kept in disinfectant and the mouth-piece changed for each candidate. Preferably five observations should be taken and recorded in litres and fractions of a litre.

2. *Breath-holding.*—The candidate is asked to expire audibly as deeply as possible and then to fill the lungs fully (but not to absolute distension) and to hold the breath with the nose clipped. The reason for the audible expiration is that it has been observed that some subjects suffering from stress have lost the power of expiring fully, and a marked shortening of time taken to expire as fully as possible may afford an indication of such loss of power. The time for which the breath is held is noted, and the candidate is then asked the reason for giving up. This should be recorded. The candidate must not be told the significance of the test, nor the time he is expected to hold his breath. On no account may he time himself. The demeanour of the candidate during the test is noted, also the degree of discomfort endured and the amount of resolution displayed.

Reason for Ceasing.—Normally an answer such as "I had to give up," "I felt I should burst," "I wanted to breathe," is given. Subjects suffering from marked disability at altitudes almost invariably return an abnormal answer—e.g., "I became giddy or dizzy," "Things went blurred," "The blood rushed to my temples," "I began to feel squeamish." Where the answer is deemed not to be normal the candidate's own words should be given.

3. *Expiratory Force.*—The candidate is instructed to hold his lips around the mouth-piece with the thumb and forefinger of each hand, at the same time pressing against the cheeks so that these take no part in the performance of the test. After drawing in a full inspiration through the nose, he is told to blow the mercury steadily as high as possible, being sure to work the abdominal musculature during the process. On no account must the candidate be allowed to swing the mercury up violently, and in all cases the height of any initial swing is to be disregarded. The reason for holding the cheeks is that it has been found that in some cases the mercury may be forced up to abnormal heights by the action of the cheek muscles. The number of mm. Hg blown is recorded. The first test is made with the scale turned away. The candidate is then asked to repeat the performance while looking at the column. The resolute candidate may, under these conditions, considerably exceed the effort which he did not see, in this way affording some indication of his mental make-up. On the other hand, a

ON THE VALUE OF APPARATUS AND TECHNIQUE IN MEDICAL RESEARCH.[1]

BY SIR ALMROTH WRIGHT, M.D., F.R.S.,
PRINCIPAL OF THE INSTITUTE FOR PATHOLOGY AND RESEARCH, ST MARY'S HOSPITAL, LONDON.

IN all inquisition into the causation of pathological events, and into the efficacy of treatment—in other words, in all medical research—adjudication by empirical methods—i.e., by observation unaided by apparatus and technique—should be superseded by adjudication undertaken with the help of apparatus and technique.

What Empirical Methods Promise.

Empirical methods take cognisance only of what comes, without our going in quest of it, into our field of experience; and they take into account only that knowledge which is brought to us directly by our five senses. In other words, in empiricism we have that which unregenerate man most desires: an evangel which proscribes all delving below the surface of things, all going in quest of knowledge, all employment of apparatus, and all troublesome technique—in short, a gospel which holds out promise of knowledge unpurchased by arduous labour.

In reality the promise that is held out is merely deceptive. It is quite true that so long as inquiry is confined to observing and noting the succession of events in individual cases it can proceed with a minimum of intellectual effort. But if, afterwards, the observer should wish to achieve something that will endure: if he wants some generalisation—some chain of cause and consequence—to come to light, then he will find out that this means severe intellectual exertion. He will very soon then come to know how difficult a thing it is to assemble and sift and complete one's observational data, and to procure a proper complement of control cases. And presently, also, he will discover that when, at the completion of a cumulative experiment all the fallacies of empirical observation, and also those of statistical or experiential evaluation have been allowed for, there will generally be left over very little of assured knowledge—often so little as not to be worth the pains of gathering in.

Where they Lead into Error.

We may take the case of an experiment undertaken for testing the efficacy of a therapeutic agent:—

(1) Already in the initial operation of selecting clinical material for experimentation empirical clinical methods will mislead. Instead of their furnishing cases which are all in fundamental respects alike, they furnish a congeries of more or less heterogeneous cases.

(2) Again, in the next operation, that of giving to each of the cases which is to receive treatment an equal dose of the therapeutic agent, empiricism may involve us in error. We may easily be led astray if we assume from the fact that we administer the same dose to each patient that the same dose is in each case absorbed and brought into operation.

(3) Again, the doctrine that judgment must be based always on overt signs will, in judging the patient's condition after treatment, often mislead us. Abatement of symptoms may, for example, be registered as definite cure, and death from intercurrent causes may be ascribed to inefficacious treatment.

(4) Lastly, the principle that we must in every case judge by criteria registered directly by the senses will not seldom bring us into conflict with that principle of logic which prescribes that we should in experimentation—so as to leave no loophole for the intervention of other causes—fix our attention upon the immediately sequent and directly affiliated event, and should refrain from vaulting by, let me call it, a *saltus empiricus*, directly from the application of a remedy to some distant and perhaps doubtfully affiliated event.

To every man who has a conception of the complexity of nature, every *saltus empiricus* is distasteful. Such a man will wish, in investigating chains of causation, to search in every case only for the next following link. In other language, he will wish to progress only from step to step, never letting anything hustle him off his *passus scientificus prudens*.

The man who lives no life within the brain, and has no conception of the complexity of nature—"your plain, practical man" as he self-appreciatingly styles himself—is always hankering after the procedure here called the *saltus empiricus*. He tells you—your statistician aiding and abetting him—that this procedure should, whenever possible, be employed, and that it is nothing but simple good common-sense to eliminate from consideration intermediate links in a chain of causation.

Subsequent Logical Operations.

Let us now turn to the subsequent logical operations, and see how, by the help of these, the empiricist—the man who believes in the passive observation which dispenses with inquisition and apparatus and technique—tries to extricate himself from the series of errors into which that policy leads him. It is familiar matter that he trusts here to cumulative experimentation with experiential or statistical evaluation.

By *cumulative experimentation* would be denoted that form of experimentation which has already been in question: that form where a group of treated and untreated cases are compared. By *experiential evaluation* would be denoted the procedure of keeping a rough account in one's head of the treated and untreated cases, taking into consideration in each case, so far as possible, all the significant points. By *statistical evaluation* would be denoted the procedure of arbitrarily selecting one particular criterion, and counting the exact proportion of cases in each group which satisfy and fail to satisfy it.

It will be worth while considering whether we can by these means arrive at trustworthy generalisations with respect to causal connexion or therapeutic efficiency. That is in reality to raise the whole question of the value of *cumulative experiments, experience,* and *statistics* in medicine.

We may begin by distinguishing two types of medical treatment. The *first* is one which may be said to float as an ideal vision before the eyes of us all—doctors and quacks and laymen. It is that in which *specific cures* are brought into operation after the method of the penny in the slot. The *second* is what we may denote *general medical treatment*.

The former type of treatment may be said to have taken scientific shape, on the one hand, in antitoxic serum-therapy, and, on the other hand, in the specific *chemo-* or *pharmaco-therapy* of Ehrlich. In either case we bring into operation therapeutic agents which are *monotropic*—i.e., agents which have a highly *specific neutralising* or *inimical affinity* for the particular pathogenetic chemical element we desire to combat.

Testing by Cumulative Experiment.

With regard to testing the efficacy of such *curative agents* by the method of cumulative experiment we may usefully note the following:—

(1) When we employ these agents we limit ourselves to our one therapeutic agent, and we give each patient treated the same dose, or series of doses.

This tying ourselves down to using only one therapeutic measure, and this strict adherence to schedule, furnish the *sine qua non* for the comparison of a group of treated with a group of untreated cases.

(2) In pharmaco-therapy we almost invariably attack either a microbe or a microbic toxin—that is, we take as our chemical target an element alien to the body. It is a direct corollary of this that the organism of the patient will (we, of course, assume our chemical agent to be really monotropic) be out of our line of fire and untouched.

---

[1] Being the substance of an argument in the preface to the second [illegible] of Technique of the Teat and Capillary Glass T[illegible] [illegible] and Company, Ltd., 1921. Price 42*s*.)

estimating the degree of infection, pointing out that it is of particular value when no other signs can be found as enabling correct early treatment to be adopted. Recently Dreyer and Burrell (1920)[9] have again drawn attention to the value of spirometry in connexion with the early diagnosis of phthisis.

Observations as regards vital capacity were made in a number of other conditions—e.g., bronchial catarrh, acute pneumonia, empyema, emphysema, asthma, hypertrophy of liver and spleen, ascites, scrofula, &c. (for literature see Arnold).[8] Generally speaking, it may be said that the vital capacity was found to be diminished in all diseases in which the airways become filled with secretions, and in conditions in which the lung is compressed. In emphysema the vital capacity is diminished, particularly in relation to chest circumference (Arnold).

Bohr[4] has shown that the residual air is increased in emphysema, the mid-capacity of the lung being increased. Siebeck[10] has confirmed this and shown that a similar condition appertains in decompensated heart cases, an observation also made by Rubow.[11]

Peabody and Wentworth[5] have shown that cases of heart disease, which become dyspnœic more readily than healthy subjects, suffer from a diminished vital capacity. They find that this diminution accords well with the clinical condition. They regard the dyspnœa as being due to the inability of such cases to increase the depth of respiration in normal fashion. In their opinion, any condition which limits the possibility of increasing the volume of air breathed per minute is a very important factor in causing the production of dyspnœa. They express the opinion, therefore, that the determination of the vital capacity offers a clinical test as to the functional efficiency of the heart, since compensated cases who do not suffer from dyspnœa have a normal vital capacity according to their method of calculation.

In my experiments the measurement of vital capacity was used in conjunction with other tests to see whether any functional relationship existed between such tests in successful and unsuccessful officers. With respect to fixing a standard it has to be borne in mind that in the earlier days of the war officers engaged in flying were, generally speaking, not chosen below a certain height and standard of physique, owing to their inability to manipulate machines, nor above a certain height and weight, owing to their inability to accommodate themselves to the relatively small machines and to the undesirability of having heavy individuals for flying purposes. With the first measurements it soon became obvious that officers who could not fly high possessed a small vital capacity compared to those who were successfully carrying on. This was particularly marked in those who were suffering from flying strain; in such the vital capacity was found to be what might be termed absurdly small, often from 2500 c.cm. to 3000 c.cm. instead of approximately 4000 c.cm. usually found in the fit flying officer. It is to this falling away of the vital capacity as a result of exposure to strain that I wish to draw particular attention. Having discovered its existence I endeavoured to find out where exactly the discrepancy lay by taking observations of the tidal air, complemental, and supplemental air. At first I tried to make relatively accurate experiments by means of prolonged observations with a mask and inspiratory and expiratory valves. It was found that the wearing of a mask tended to alter the breathing of the subjects, and it was difficult to overcome the resistance of the valves. Moreover, subjects suffering from strain did not care about such apparatus and sometimes objected to its use. For the measurement of the complemental and supplemental air, therefore, it was found simpler to ask the subjects to endeavour to breathe as fully as possible after making a normal quiet inspiration or expiration. After about 20 observations I satisfied myself that there was little or no falling away on the inspiratory side—the complemental air averaging in all between the standard figures of 1500–2000 c.cm. or over. On the other hand, the measurement of the supplemental air gave results which showed that in officers suffering from strain the supplemental air is generally decreased, especially in those who have been engaged for a long period in high flying (21,000 feet), in whom it may measure no more than 500–800 c.cm. Further observations quickly confirmed the view that in officers suffering from strain the diminution of the vital capacity was due to their inability to expire sufficiently to empty the lungs to their full capacity. This was confirmed also by the observations that it was difficult for such officers to blow forcibly through the spirometer, or to blow up a five-litre bag. I do not think attention has been drawn to this point before, but it is undoubtedly one of considerable importance. The fit individual is possessed of a good vital capacity because he has the power adequately to empty his lungs by expiration. This power also is not greatly reduced by bodily strain. In the unfit individual bodily strain does affect the capacity. The diminution of the vital capacity of an individual leads to deficient ventilation of the lungs and accounts for the condition which I have observed in tired pilots, and which has also been recorded by Corbett and Bazett[12]—namely, that instead of responding to muscular effort by an increased depth of respiration they quickly become breathless and pant in short ineffective gasps as the result of exercise. Officers themselves are aware that they now easily get out of breath on the ground, while in the air they begin noticeably to breathe deeply at altitudes at which previously they were unaffected, so far as they themselves had noticed. Observations made upon candidates who have never flown have convinced me that such respiratory inefficiency is not confined to the flying officer. It is quite common to meet among candidates for aviation individuals whose respiratory capacity is small. Such candidates have usually led sedentary lives and indulged but little in health-giving exercise.

The case may be stated briefly as follows. The normal fit individual is possessed of sufficient expiratory force to keep his residual air near the physiological minimum (say, 1000 c.cm.). In the unfit person, owing to lack of good expiratory tone, the vital capacity becomes decreased and the residual air increased, with the result that the ventilation capacity of the individual is greatly decreased. This can be seen by a consideration of the following figures: Suppose a fit man has a vital capacity of 4000 c.cm. (ventilation capacity of 4 to 1); when as the result of strain or unfitness his vital capacity is reduced to 3500 c.cm. his residual air increases to 1500 c.cm., and his ventilation capacity is now only 2⅓ to 1; a reduction of the vital capacity to 3000 c.cm. and an increase of the residual air to 2000 c.cm. gives a ventilation capacity of 1½ : 1, instead of 4 : 1. As already stated, such vital capacities were frequently found and observation showed that they increased with treatment, rest, and exercise. I have had many examples of this. Recently I saw a flying officer who, on his return from Egypt after a considerable period of high flying followed by strain, had at his first examination a vital capacity of 2200 c.cm. Six months later, as the result of rest and exercise, it had increased to 5600 c.cm.

In my next lecture I shall give other examples of the increase of vital capacity by special expiratory exercises. Not only is an increased residual air a disadvantage when exercise is taken, but when the body is resting a large residual air necessitates a greater inspiration to bring about adequate ventilation of the lungs. It appears quite probable that after a time ventilation becomes relatively inadequate, so that an anoxæmia in the arterial blood results, the respiratory and other centres in consequence becoming more sensitive to stimulation by the CO_2 tension of the arterial blood. It may even be that in certain cases the CO_2 tension of the arterial blood is increased; Poulton and Campbell[13] have found that this condition occurs in cases of heart disease and it appears possible that a similar state of affairs may be found in unfit people who are respiratorily deficient in the way I have described. Such a state would readily explain the reason of the breathlessness on exertion, and the greater susceptibility to diminishing oxygen-tensions in the lung (see Table I.). It would also conduce to a hyperexcitability of the central nervous system generally.

a therapeutic agent which exerts a specific and immediate or quasi-immediate result. The *second* is the case where we apply as an element of general medical or surgical treatment a code of procedure which makes so great a difference in the results as to exclude the fallacy of chance; and where, further, the fallacy of superior professional skill being enlisted in favour of the one or other method is excluded, as it is where man after man has made a comparative trial of the two methods.

Here a favourable or unfavourable verdict upon a therapeutic measure can go forth if the procedure under trial is competent to swamp the effects of all the measures employed in association with it, and to dissever in a manifest manner the group of cases which have received only general treatment from those which have received also the special treatment.

Again, in respect to trial and error experiments for the scientific betterment of therapeutics, the conditions in the domain of general medicine are infinitely less favourable than in pharmaco-therapy. In the latter we have, so far as our therapeutic agent is concerned, to consider only modifications in its dosage and eventual modifications in its chemical structure. In general medical treatment—for here we apply a multiplicity of procedures—we have an infinite number of variables, each one of which would be competent to modify the result. We can, therefore, here never hope by cumulative clinical experiments to do anything appreciable for the betterment of treatment.

Still in other respects—respects which materially affect experiential and statistical evaluation—are the conditions in general medical treatment different from those in pharmaco-therapy. We proceed in pharmaco-therapy on the conception that all the phenomena of disease proceed from a single cause and are connected up single file like the links in a simple chain of causation. Conformably with this mental picture we expect the retrenchment of the original pathogenetic agent (microbe or toxin) to annul the whole train of pathological phenomena and utterly abolish the ailment. That is what we have in mind when we speak of a *cure*.

Cures thus understood furnish material which satisfies the requirements of statistics. These are satisfied, first, in the respect that we have in *cures* (i.e., in the purging of the organism from a pathogenetic element) data which are quite definite and clean cut, and easy to appraise; and, secondly, in the respect that we have in the kind of cures here in view (those affected by pharmaco-therapy), effects which are directly engendered and attributable exclusively to the agent we bring into operation. The importance of this for the evaluation of therapeutic measures will presently appear.

Conception of Sanation in Place of Cure.

In general medical treatment we proceed upon a different and unquestionably profounder view of the processes of disease. Instead of regarding these as proceeding from a single cause and ranged up in the form of a single chain of causation (a picture in reality applicable only to the initial events in any disease), we now perceive that each morbid phenomenon is the resultant of many causal factors, and that in consonance with this our therapeutic measures must be directed against a multiplicity of pathogenetic forces.

In a word, we now put in the place of the conception of *cure* the conception of *sanation*. This is indicated by a change of vocabulary. We tacitly drop the term *cure* and employ instead the terms *clinical improvement*, *recuperation*, *recovery*, *convalescence*, and *restoration of health*.

This change of programme makes, when we come to evaluation, an important difference; for the form of clinical achievement at which we now aim is one which does not lend itself to statistical evaluation.

False Conclusions from Individual Experiences.

Clinical appraisement in connexion with general medical treatment conducts also into other error. It not [illegible]ently leads us to draw from individual e[illegible] false conclusions. When a patient gets well we are, without regard to the circumstance that our treatment may have been ineffective or hurtful, prone to conclude that treatment has not only in the particular case been effective, but also that it will be universally useful. Again, where the clinical event disappoints expectation, we are, without regard to the circumstance that the therapeutic agent may have perfectly accomplished its mission, prone to regard that agent not only as having in that particular case been useless, but as one which will on all occasions be useless.

The reason for such misjudgments is to be found in that fact that we here judge by contingent and indirectly engendered effects.

It will perhaps be profitable to show, first by an example culled from our domestic surroundings and then from one supplied by medicine, how judgment by contingent and indirectly engendered effects conducts into error.

When our electric bells have refused to function, and the filling of the battery with water has made them ring, we might, if we knew no more about the mechanism of those bells than the ordinary man does about the body, quite well suppose the pouring in of water to produce without other intermediation the ringing of the bells. And, again, if the filling up of the battery failed to make the bells ring, we might quite naturally pronounce this pouring in of water a quite futile procedure.

Both kinds of false inference would clearly be due to our neglecting to investigate the direct effect of pouring in water, and arrogating to ourselves the right to draw by experiential or statistical evaluation conclusions from remote effects.

Arrest of Hæmorrhage as an Example.

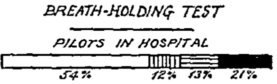
A comparable example in medicine would be adjudicating by clinical effects upon the efficacy of measures for the arrest of hæmorrhage. Sustained bleeding may be due (*a*) to delayed blood coagulation; (*b*) to the unsatisfactory quality of the fibrin meshwork; or (*c*) to deficiency of red corpuscles—these last being required to fill out the meshwork of fibrin and convert this into a sufficiently massive tampon.

This once comprehended, it becomes clear that when arrest of hæmorrhage—or, to be more precise, prompt and durable hæmostasis—has in this or that instance followed a particular therapeutic intervention, that gives no warranty for assuming that the result has here (any more than in our last example) been directly produced by the procedure adopted, nor yet that this will prove a method of general utility. Nor, again, when a particular therapeutic intervention has failed to arrest hæmorrhage does that warrant the conclusion that the method in question has failed in its appointed task, or that the accomplishment of that task will never be contributory to the arrest of hæmorrhage.

With regard to such misjudgments based on individual experiences the accepted statistical doctrine teaches that all false judgments are quashed when we collect enough cases. That is false doctrine. When cumulative experiments are undertaken with heterogeneous clinical material our misjudgments need never be reversed. In fact, erroneous verdicts will almost inevitably be pronounced. If, for example, we administer to a group of undifferentiated cases of bleeding—a group in which by chance each of our three varieties of bleeding is equally represented—a remedy which is sovereign for one of those varieties of bleeding, our remedy would be pronounced unsatisfactory as giving success only in one case out of three. And if in our experimental group the class of case for which our remedy was appropriate was unrepresented, or only very scantily represented, the statistical conclusion would be that that remedy was utterly useless.

And—let this be observed—we should, failing the application of laboratory methods for differentiating the different kinds of bleeding, never learn whether the appropriate variety of bleeding was included in our experiment, and in the case where all varieties were included in what proportions the several kinds were included. We should, in fact, be confronted with the executive the normal time was fixed at 60 seconds approximately; in the tired pilots the time was found to be 51 seconds; in pilots who had to be taken off flying for flying strain, 49 seconds. Besides giving indication as to the likelihood (when the time is short and an abnormal answer is given) of the subject suffering from oxygen-want at altitudes, the breath-holding test may also be taken to give indication as to the stability of the respiratory centre to diminished oxygen-tension. Experience with the test shows that great instability of this centre is also accompanied by instability of the vaso-motor and coördinated centres and may also, in many cases, reflect instability of the nervous system generally. The test is also of psychological value, since observation of the subject during the test gives an indication of the resolution with which he will carry on under conditions involving gradually increasing discomfort. The value of the breath-holding test in aiding in an assessment of flying capacity is indicated by the following chart (Fig. 1). The fit experienced pilots numbered 52 and were chosen by the executive; the short-service pilots had suffered from no disability in the air and were anxious to obtain short-service commissions; the civilian pilots had flown on an average 800 hours, had suffered from no disability in the air, and were applying for licence to carry passengers and goods. The stressed pilots (home service) were returning from active service overseas and were tired but not in need of medical treatment, whereas the stressed pilots (off flying) were being treated in hospital or performing ground duties only. The pilots in hospital were not selected and, although for the most part suffering from strain, included subjects who were suffering from temporary illness such as influenza or conditions requiring surgical treatment. This accounts for the percentage (21 per cent.) who could hold their breath the normal 70 seconds or over. (Fig. 1). The next figure indicates that among 79 pupils who qualified but broke down from medical causes, including acute infectious diseases, within one year of acceptance, there is a tendency for the breath-holding capacity on admission to be on the small side. From actual experience it is known that those who fail medically display a small breath-holding capacity at the time of failure. The figures indicate that there is ground for the view that it is advisable to admit candidates with a breath-holding capacity approximating to that of the fit flying officer as selected by the executive and to give special consideration before admittance to those whose breath-holding capacity approximates to that of the tired or broken-down pilot (Fig. 2).

FIG. 1.



The Test for Expiratory Force.

At the time that this test was first employed in the examination of the flying officer I did not know that John Hutchinson[2] had already used the test. As the result of his observations John Hutchinson expressed the opinion that "a dynamic instrument like the hæmodynamometer would be useful to those whose duty it is to examine men for certain public services, as for the army, navy, police, fire-brigade, &c.; with care it would often detect disease." Hutchinson was of the opinion that measurement of the inspiratory power was more valuable than that of the expiratory power, which he found more apt to vary. It is to be noted that he measured such forces through the nostrils. In this connexion I must observe that I also tried this method, but found that I had to give it up owing to the discomfort induced in many subjects, who objected most strongly to this form of the test. For this reason, therefore, the method of performing the test in which movement of the lips and cheeks is prevented is still used, and despite criticism on the point, it is on the whole satisfactory. That is to say, that it is desirable that the expiratory force in man shall at least reach the minimum standard of 80 mm. Hg, preferably the average of 110 mm. Hg, otherwise a cause should be sought for the inefficiency, and, generally speaking, it may be assumed that bodily endurance is not likely to be good. In regard to Hutchinson's conclusion as to the superiority of the inspiratory force, it is interesting to note that this was formed on account of the greater variability of this power. In my opinion, it is this great variability which lends value to the test for expiratory force. Hutchinson's figures for Freeman the giant show that, as he became more and more ill with phthisis, his expiratory force declined more than did his inspiratory; there was a decline of 38 mm. Hg in the former from 127 to 89 mm. Hg and of 60 in the latter (160–100 mm. Hg). I have noticed that my own expiratory force is greatly lessened by an attack of "influenza," and returns to normal as my physical condition improves. Hutchinson gives the variation of expiratory force from 50–250 mm. Hg, observing that it was high in the Thames police, sailors, firemen, and pugilists, less in paupers and gentlemen, low in pressmen, and lowest in compositors. It was also low in cases of disease. The various values which I have found in regard to this test are given later, the standard for fitness being set upon specially selected officers.

animals. The quantity of virus necessary to give this degree of immunity was found to be less than 1/100,000 of the quantity required to cause the disease. (Tokio Ijishinshi, No. 2204, Nov. 20th, 1920.)

This important discovery threw new light upon prophylactic inoculation for many of those acute infectious diseases, specific treatment of which had till then been thought impossible. I determined to apply Dr. Kusama's method of prophylactic inoculation to measles and other diseases. I intended to begin with measles, as a comparatively mild disease which no one can escape, but unfortunately for my purpose, all five of my own children had already had the disease, and I was unable to procure others. Just at the time a typical scarlet fever patient came into my hospital. I made up my mind to carry out a test of prophylactic inoculation against scarlet fever, using my children as the experimental objects.

Previous Experimental Work.

Before the prophylactic inoculation in the human body against scarlet fever can be undertaken, the distribution of the virus in the human body and its virulence in the particular epidemic, must be determined. It is necessary to find out the minimal morbid dose of the blood or secretions which contain the virus. Judging from the literature, experimental results have differed according to the intensity of the virus in various epidemics. Grünbaum, Cantacuzene, Bernhardt, Landsteiner, Levaditi and Prasek, Levaditi and Danulesco, and Koga obtained blood or secretions from the throat or tonsils of scarlet fever patients just before the appearance of the eruption, and smeared them over the throats of, or injected them subcutaneously into, gorillas or monkeys. From the results obtained there is no doubt that the blood and secretions named contain the virus. The quantity of blood used was more than the minimal morbid dose. Bernhardt produced the disease in a monkey with 0·25 c.cm. of fluid from a vesicle of the skin taken from a patient four days after onset of the fever. There have been no experiments on human beings, and consequently the minimal morbid dose for man is not known. It is probably less than 0·1 c.cm. It was hardly practicable to determine the minimal dose of the virus of this year's epidemic before the quantity of the prophylactic dose was determined. Therefore, according to the results obtained by previous investigators on monkeys, I used in the following experiment 0·1 c.cm. as the minimal morbid dose of the virus of the present epidemic.

I.—*Prophylactic Inoculation.*

Materials.—Blood obtained from the median vein of arm of a scarlet fever patient S., a girl of 11 years old. The past history and present illness described in brief are as follows: General health had been always good; she had had measles and had been vaccinated once; no hereditary disease (tuberculosis, syphilis, &c.). Present illness began Nov. 24th, 1920, with sudden chills; examination on admission to the hospital the next day showed bright scarlet rash over the vault and arch of the mouth, both tonsils swollen, the root of tongue coated yellowish-white, and tip of tongue bright scarlet; the rash seen faintly over face, neck, and chest. Temperature was 39·6° C. On the third day the rash became more distinct, and spread over the inner sides of the thighs; the fever rose and patient became delirious. On the fourth day the rash extended over all the extremities; distinct strawberry tongue; face bright scarlet except around the mouth. These conditions continued during fifth and sixth days, and on the eleventh day scaly desquamation began. This patient had bronchitis and the fever recurred, but in a few days the temperature returned to normal.

The blood was taken on the sixth day of illness. The sterile syringe contained 2 per cent. sodium citrate in physiological salt solution, and the same amount of blood was taken from the median vein of the arm. The blood was transferred to four test tubes containing a fixed amount of 1 per cent. sodium citrate solution, c.cm. of the diluted solution in the test tubes contained 0·0001 c.cm. of the patient's blood. The blood was thus diluted 10,000 times with the citrated salt solution. This dilution was used as the material for injection. The experimental objects were five of my children, all in good health; they had all had measles and had been vaccinated. The eldest daughter had erysipelas at 9 years old, but no other serious diseases.

Experiment.—On Nov. 29th, after shaking the tubes containing the diluted blood so that the virus would be equally distributed in the solution, certain amounts of the solution were injected subcutaneously in the interscapular regions. The ages of the children and the amounts of diluted blood injected were as follows:

Names.	Ages.	C.cm. injected.	Names.	Ages.	C.cm. injected.
Girl E.	10	1	Girl H.	6	1
Girl A.	8	1	Boy J.	3	0·5
Boy I.	7	1			

From time to time during the next three weeks I carefully examined their temperatures, urine, throats, and general symptoms. In all cases there was no local reaction in the shape of swelling, redness, or pain, and absolutely no general symptoms (e.g., fever, pharyngitis, albumin in urine). The two elder girls went to school and the rest of the children played around the house as usual. The above experiments prove that sufficient dilution of injected blood renders it powerless to cause the disease in human subjects. In order to discover whether immunity was conferred by injections I determined to try an infection experiment with proper material; on Jan. 4th, 1921, I obtained a scarlet fever patient through the kindness of Dr. Kurabe, and made the following infection experiments.

II.—*Infection Experiments.*

M., a schoolboy 17 years old, whose general health had been good; he had had measles and had been vaccinated; no serious or hereditary disease. The present illness began on Dec. 31st, 1920, with sudden attacks of shivering. Examination on Jan. 5th, 1921, showed eruption all over the face, except around the mouth, and over the body. Tonsils and tongue showed typical picture of scarlet fever; temperature was 39·6° C. and pulse 120; delirium and muttering at times. On Jan. 5th, at 1 P.M., the blood was taken as in the previous experiment, and diluted with citrated (1 per cent.) physiological salt solution so that 1 c.cm. of the final dilution contained 0·1 c.cm. of blood. The above dilution was injected subcutaneously into four of the children in the interscapular region.

Names.	C.cm. injected.	Names.	C.cm. injected.
Girl E.	1·5	Boy I.	1·5
Girl A.	1·5	Boy J.	0·6

I did not know how much of the virus of the present epidemic of scarlet fever was necessary to infect a human being. To determine the minimal morbid dose in man is impossible, and as Bernhardt infected a monkey with 0·25 c.cm. of the fluid obtained from a skin vesicle, I presumed that 0·1 c.cm. would probably infect a human being, so I took 0·15 c.cm. of the blood for the experiments. During the next three weeks I again carefully observed the children as before. There were no local reactions and no general symptoms.

The above experiments prove that injection of 0·0001 c.cm. of the blood of a scarlet fever patient into children produces no reaction, but confers a degree of active immunity sufficient to prevent occurrence of the disease on introduction of the virus contained in 0·15 c.cm. of blood.

Clinical observation and animal experiment show that scarlet fever is spread directly or indirectly by the secretions of the patient's nose and mouth. In natural infection the virus transmitted from the one to the other must be very minute. From the immunity derived from an injection of 0·15 c.cm. of blood given subcutaneously it might safely be assumed to prevent ordinary infection. I therefore made the following experiments in imitation of natural infection.

Our task of adjudication will hereby be facilitated. For clearly the circumstance that the patient's body is, as it were, an unaffected spectator contributing nothing to the result, will eliminate many possibilities of fallacy, and bring out more clearly the specific effect of the remedy.

(3) With the class of agents we are here considering the clinical results are, when obtained, obtained promptly. In virtue of this we are spared those possibilities of fallacy which are incident to the *saltus empiricus*.

All this can go into a nutshell. When treatment conforms to the type of pharmaco-therapy, it will be possible to adjudicate upon its efficacy by cumulative experimentation and experiential or statistical evaluation.

The Element of Chance.

But a reservation must here be made. In every cumulative experiment the operations of chance—i.e., the intervention of other causes—will constitute a source of error. This error of chance may be so small as to be practically negligible. This will be the case where we are dealing with sensibly homogeneous clinical material; are operating with a really efficacious remedy (i.e., an agent which has a definite inimical affinity to the pathological element we are combating); *and are employing a proper scheme of dosage.* Under these circumstances we shall not need in testing a remedy (and the same principle will apply in investigating a pathogenetic connexion) to employ large numbers of treated and untreated patients; and it will be possible, dispensing with statistics, to arrive by the experiential method at prompt and trustworthy judgments.

When, on the contrary, we are dealing with sensibly heterogeneous clinical material, or are operating with a pharmacological agent which has no very definite inimical affinity for the pathogenetic agent we are combating, or, again, when we are *employing an ill-chosen scheme of doses*, the element of chance will exert a dominating influence.

In such cases it will be necessary to employ correspondingly larger numbers of treated and untreated cases. That involves us in difficulties. The collection of sufficient numbers of cases will involve very considerable expenditure both of time and energy. Further, when the patients are collected it will require a considerable gift of tact to carry out that portion of the experiment which consists in leaving the control cases entirely without treatment. And, finally, the experimenter will have to shoulder a certain moral burden in applying the treatment in cases where it is contra-indicated, and withholding here such other treatment as would seem to hold out more promise. In brief, there are not only physical difficulties, but also humanitarian objections to the carrying out of clinical cumulative experiments on any large scale. Moreover, as the physical and moral difficulties *increase*, the intellectual harvest from the work becomes less and less. Finally, the task becomes so patently unremunerative that every reasonable man will cry off from statistical inquiry.

Where Statistics Leave us in the Lurch.

There is yet another aspect of the question—specially important for those of us occupied in research. When a therapeutic method gives entirely satisfactory results, or when—and this comes to the same—we are satisfied with those obtained, we have then nothing to ask from a method of evaluation except that it should blazon abroad our achievements and make propaganda. That is, for example, all that is aimed at and achieved by the statistics of anti-typhoid inoculation.

If, however, our treatment is unsuccessful, or if we do not account it sufficiently satisfactory, what we then want is not the exact number of successful and unsuccessful cases, but particulars such as are not furnished by statistics. We want, for the systematic trial and error experiments upon which all scientific betterment of therapeutics depends, to know whether our failure or comparative failure has been due to our having had under treatment a heterogeneous group; or whether it is to be ascribed to the inherent ineffectiveness (i.e., the inappropriate chemical constitution) of the therapeutic agent; or to an error in dosage; or other specifiable cause.

In default of information of that kind the only course which lies open to us is that of launching out again and again into cumulative experiments with the original treatment altered each time in such fashion as caprice may suggest. *To put ourselves in heart*, it is necessary to hypnotise ourselves on each occasion with *the idea that this time, at last, chance is going to smile upon our random experimentation.*

All the poignant futility of such self-suggestion is made manifest in the example of quinine. Here cumulative experiments of a sort have followed each other for—it must be now close upon—three hundred years. And from all those years of scientifically unguided experimentation with different preparations and sundry and divers doses, all that has clearly emerged is: that while, *in certain forms of malaria and in* conditions which cannot be clearly particularised, therapeutic effects are not unfrequently achieved, quinine is very far from furnishing a cure for malaria generally. Quite other information—information that cumulative empirical experiment cannot supply—is required for the improvement of treatment. We require to know *what concentration of quinine should* be achieved in the blood in each different form and stage of malaria, and how long this concentration should be maintained. And, above all, we require to know whether the organism of the patient should, when quinine is administered, *play the part* of the neutral spectator, or whether the doses of the drug should be *so adjusted as to allow of the organism of* the patient joining in with a therapeutic effort.

This in itself suffices to show that even in the domain assigned to pharmaco-therapy—in other words, in the ideally favourable field for the employment of the method—cumulative experiment is almost unserviceable for the improvement of treatment.

Cumulative Clinical Experiment inapplicable to General Medical Treatment.

It is now time to see whether cumulative clinical experiment can be put to any use in connexion with general medical treatment. In pharmaco-therapy the programme is to take in hand the disease in its earlier stages, to leave the organism of the patient out of account, and let the therapeutic agent do the work. In general medical treatment the programme is entirely different. We now aspire to exercise directive control over the physiological machinery of the body—checking from moment *to moment* such reactions as may be excessive, spurring on those that are torpid, and supplementing, so far as we can, the responses which make default by supplementary responses artificially evoked. Further, in general medical treatment we are prepared to undertake the patient in any stage in the disease. And the ideal we set before ourselves is that of *trying to pilot him* back to health by constant opportunist intervention.

Reflection will show that such a programme is incompatible with the undertaking of any cumulative experiment. It is, as we have seen, a precondition for every such experiment that there shall be a *definite* schedule of treatment which is not departed from, and that the *cases shall* distribute themselves into two sharply contrasted groups. But in general medical treatment, as in the steering of a motor-car or a ship in a crowded thoroughfare or fairway, we work *not by schedule*, but by following the indications of the moment. And as we never *encounter precisely* the same set of circumstances, we never treat two cases *in exactly the same way*; and thus can never obtain a group of cases treated all in one way, to contrast with a group of cases treated all in another.

Two Possible Exceptions.

To the general proposition that the method of cumulative experiment is inapplicable when general medical treatment is in question, there are two exceptions. The *first* is the case when we superadd considered a special form of chronic middle-ear "dry catarrh." Moos, in 1867, and Politzer, in 1893 and 1901, gave reasons for considering it a primary disease of the bony labyrinth, as in the great majority of cases the middle-ear mucous membrane was found perfectly normal, while in many preparations the most marked changes were found in the deeper layers away from the mucous membrane. Specimens were soon noted which showed scattered islets of similar bony changes throughout the petrous bone, with or without stapes involvement. Further, labyrinth-atrophy was sometimes met with on the affected or on the opposite side, and Manasse brought forward a nerve-degeneration theory which was supported by many. Brühl, in an excellent recent summary of our knowledge of the disease, points out that the facts suggest rather that labyrinth-atrophy, when met with, must be secondary (or a post-mortem change), Manasse himself having demonstrated a preparation showing stapes-fixation without definite labyrinth change, and in his more recent works (1914 and 1917) coming nearer to Brühl's view that the primary change is in the bone. As to vascular theories, O. Mayer, Cornet, and Gray have all wholly or largely given up earlier theories of theirs as to its origin in local anæmia (arterio-sclerosis, syphilitic endarteritis, or thrombosis), and this clears the ground somewhat for a basis for radiation treatment. Mayer now considers it an "undescribed variety of ostitis fibrosa," an "osteofibromatosis." Instead of anæmia there is increased vascularity (clinically suggested by the sometimes seen "flamingo-red" flush on the promontory), it presents appearances like Volkmann's "vascular ostitis," is a "chronic metaplastic ostitis" (Manasse), and has apparently close relations with osteomalacia. As Ferreri says, there seems "a great affinity" between osteomalacia, rickets, and otosclerosis. All the patients in Arcangeli's clinic with osteomalacia also had otosclerosis, and on this relationship Siebenmann's phosphorus treatment is based, whether increased ovarian internal secretion (with hyperæmic results elsewhere) or that of other endocrine glands, or calcium (Kobrak) or chloride (Cornet) retention be ultimately at fault. It must frequently at least be an endocrine gland anomaly, as Alexander has found otosclerosis in cretins (human and animal). Gray regards it now biologically as a "variation," a degeneration of the later-evolved auditory as distinct from the equilibrative mechanism of the ear (the latter fully-developed already in fishes, the former appearing with reptiles or early amphibians).

Siebenmann, on the other hand, regards it, on the basis of many histological researches from his clinic, as an over-development in the labyrinth of cartilage remnants which normally are there at least till adult life (Taniyama), especially in the region in front of and above the oval window. The labyrinth is practically full-size at birth, and if it continues to develop in the confined space it is in (Kerrison), as the skeletal bones normally do, by absorption and new bone formation, there must be marked changes, beginning, in Siebenmann's view, at the boundary of the original cartilaginous and the later periosteally developed labyrinth-capsule. (Brühl thinks the predilection for the region in front of the oval window is due to the bony stresses set up by the pull of the tensor tympani muscle. Gray thinks that in addition the stresses set up by the continual stapes-vibrations sensitise the bone in the neighbourhood to new formations or pathological changes.)

The earliest changes are rather matter for dispute, Brühl finding them in the vessel-canals of the old periosteal bone, absorption of the bone round these, and subsequent new building of an abnormal spongy bone; Mayer, in the transformation of the connective-tissue cells of the marrow and vessel-canals into osteoblasts and osteoclasts, so that "this richly cellular fibrous marrow causes on the one side an absorption, and on the other a new growth of bone" (1912). In both ostitis and otosclerosis are found, as Sc[illegible]; Bryant, in his exhaustive analysis of the ætiology of the condition (1913) points out, increased vascularisation, granulation tissue, replacement of the normal bone by osteoid tissue, exostosis and hyperostosis, a definite line of demarcation (Pommer's cementing line), the formation of giant-cells, origin in the endosteum or periosteum, cellular marrow transformed to fibrous, and finally new atypical compact bone. Bryant calls it an "osteodystrophy." The marrow is atypical, as myelocytes and normoblasts are absent (Wolff). The giant-cells are of interest; up to 12 nuclei have been seen (Jenkins).

As Denker in his analysis of the 26 or so cases, and literature to 1904, gives nearly five pages of references, and Bryant, in 1913 (writing on the ætiology chiefly), gives seven and a half pages of references in small print, it is clear the subject is an immense one. The main point for the present purpose is that the pathology of the condition suggests that in its early stages it should be amenable to radiation treatment. Diathermy has been found to give bad results (Joseph); more is to be hoped for from the "ischæmic power of radiotherapy" (Chevriet and Bonnot), and its action on certain types and growth-stages of cells. Additional grounds for believing the treatment may be of avail are (2) the effects of radiation on growing cartilage and bone in young animals (Récamier); (3) the well-known curative effect of radiation on tuberculous bones and joints (Albert-Weil, Wetterer, Iselin, Petersen, &c.); and (4) the results of radiation on young osteomata (Chevriet and Bonnot).

Early Results of Treatment.

The first to try X ray treatment in otosclerosis, so far as I am aware, was Jaulin, in 1908. He applied 1–2 H weekly (5–7 Benoist) through an ear-speculum, the rays directed on the tympanum. 3–14 sittings were given. Of ten cases six improved: he stated they improved more in their voice-perception than could be shown by objective tests; tinnitus also improved. Schwartz treated three cases with six doses at monthly intervals, in one case with surprisingly good results, the hearing becoming practically normal; one showed no improvement, the third was slightly better. Ortloff, in Freiburg, reported ten cases in 1913, with negative results as regards improvement, a "middle-soft" Müller water-cooled tube being used, a third of a pastille being given on each of three successive days, then a 2–3 weeks interval, then another series (sometimes a pastille dose being given at one sitting with 2–3 weeks pause). Two or three series were usually given, in one case four series. The dose was measured apparently (being an unfiltered pastille dose) to the external ear: Jaulin calculated his one or two-fifth dose to the tympanum. Ortloff was not very fortunate in his choice of cases, only one had a history of one or two years (Case 6), some having eight or ten years' history of deafness. The results on the hearing, tested by Prof. Bloch's elaborate scheme, were uniformly negative; if there was slight improvement it was invariably followed by return of the tinnitus and deafness as before. (The possibility of therapeutic aim at *arrest* of the process is briefly referred to in conclusion.) As the tube-size and distance are not given it is impossible to compare the doses given by Jaulin and Ortloff, but considering the position of the oval window (behind the post. inf. quadrant of the tympanum, but partly hidden in 32 per cent., and quite hidden from the tympanum in 19 per cent.—refer. in Ortloff), and the necessity for penetrating the bone, even in the case of the most favourably placed oval window, to at least 3–4 mm. with sufficient radiation, neither Jaulin nor Ortloff seems to have used a sufficiently penetrating ray, or enough total dosage. The difficulties are certainly great. Siebenmann's cases have been treated on another scheme, and, while I should not be justified in publishing the complete technique used at Bâle (being the as yet unpublished work of others), it may be said that a cross-fire method is used on to the fenestra ovalis with a 4 mm. filter. Schemes of fractional and full the situation which presented itself in the typhoid statistics of the South African War, where the efficacy of the process of anti-typhoid inoculation was judged of by clinical methods which required of that inoculation process that it should give protection not only against typhoid fever, but also against paratyphoid A and paratyphoid B.

It is, in sober truth, "old abusing God's patience" to go on dreaming that statistical evaluation conducted with the data ordinarily supplied by clinical observation can ever conduct to any trustworthy quantitative estimate of the value of a therapeutic measure.

How Laboratory Methods remove Difficulties.

We may now examine and see in what way recourse to laboratory methods clears away the difficulties which beset the path of research. First and chiefest the employment of laboratory methods makes it possible to substitute in many cases for cumulative or group experiments (experiments where the conditions are so complicated that the individual cases give different results) crucial experiments—experiments where the conditions are so simple that each individual case gives one and the same result. These crucial experiments furnish us with a series of firmly established facts which will, like fixed points in a trigonometrical survey, supply a foundation for the mapping out of all the rest of the territory. Firmly established facts, such as are here in question, would be the fact that such and such a microbe produces such and such a disease; that a particular modification of the blood converts it into a favourable culture medium for a particular microbe or for all microbes; and that a vaccination process produces such and such changes in the blood.

A second but also supremely important function of laboratory methods is that of making of the method of cumulative experiment a more effective instrument of research.

(*a*) To begin with, laboratory methods enable us to select, out of that raw and heterogeneous material which clinical examination provides, cases which are more nearly homogeneous—in other words, better material for experiment.

(*b*) Where we administer a therapeutic agent and suspect that, by reason of non-absorption, this agent does not regularly come into operation, we can, if suitable technique for blood examination is available, ascertain whether our surmise is well founded and, if so, in what cases.

(*c*) Recourse to laboratory methods saves us from making a *saltus empiricus* and so precipitating ourselves into fallacies. When laboratory methods are at disposal we, instead of trusting to the remote effects which make themselves sensible to the unaided senses, adjudicate by direct effects. When, for example, antiseptics are applied to infected wounds, we can ascertain by the method of culture, without either question or statistical delay, whether the microbes have been exterminated or reduced in number.

(*d*) The employment of laboratory methods makes it possible when dealing with a complex procedure, such, for example, as *sanatorium treatment*, or the technique of aseptic surgery, or vaccine-therapy, to investigate the effect of the separate items of treatment instead of noting only the effect of the procedure taken as an aggregate.

(*e*) Finally, we can, by resort to laboratory methods, find out what has been achieved by treatment. We have here at disposal cultural methods, also opsonic measurements carried out in connexion with auto-inoculation procedures, and, in the case of syphilis, the Wassermann procedure and the more accurate derivative method of Dreyer and Ward.[2]

Conclusion.

In conclusion, it will be well to take brief account of two questions which, in the perusal of the above, are bound to have come up in the mind of the reader. He will have asked himself whether the recognition of the fact that clinical observation is an essentially imperfect instrument for adjudicating on the efficacy of therapeutic measures is not going to involve as its consequence the ousting of the clinical observer from his present office of expert and adjudicator in questions of therapeutics. And, again, the reader will have asked himself whether, in those domains of medicine where no appropriate laboratory methods of investigation lie ready—*and there are, of course, many such* domains—clinical cumulative experiments, such as have always been going on, should not be persisted in, and whether, at least in these scientifically untilled provinces of medicine, the clinician should not for the present be confirmed in his office of adjudicator.

Both these questions can be answered in a very few words. The first finds its answer as soon as we bring the concept *adjudication by experts* into quite sharp focus in our minds. It then becomes evident that by an expert is meant a man who carries in his head a precise mental picture of the mechanism by which an effect is produced, and who is at any rate competent to investigate such machinery. When anyone who has possessed himself of this definition is, in connexion with problems like those of the cause and treatment of shock, or the effect of anæsthetics, or the efficacy of antiseptics in an infected wound, or the treatment of malaria or vaccine-therapy, interrogated as to whether the surgeon and physician are in matters of this kind experts, his reply must inevitably be that the surgeon and the physician have in such matters, exactly like the layman, vision only of the final result.

The further question as to whether the method of cumulative clinical experiment should be persisted in in those regions of medicine in which the requisite laboratory methods of investigation do not yet exist, can be disposed of also in a few words. It is clearly not a matter of very great importance to the world whether men who are prepared to waste their time do or do not waste it over experiments which are doomed for the most part to be futile. But what does seriously matter is that it should be contended and believed that failing preciser methods of investigation, it is inevitable necessarily to have recourse to cumulative clinical experimentation, and to requisition the services of the statistician.

As doctrine that is erroneous. It may quite well be necessary, *when other means have failed*, to have recourse to clinical cumulative experiment. But the trained expert put upon the job can, given time, practically always meet the needs of the moment, or at least some of those needs, by the invention of new methods.

AN EXPERIMENTAL STUDY OF PROPHYLACTIC INOCULATION AGAINST SCARLET FEVER.

(PRELIMINARY COMMUNICATION.)

BY I. TAKAHASHI, M.D.

(*From the Kitasato Institute for Infectious Diseases, Tokio.*)

OF the acute infectious diseases caused by filtrable viruses—e.g., small-pox, hydrophobia, scarlet fever, typhus, and tsutsugamushi—only the first two can be successfully prevented by prophylactic inoculation. There are no specific treatments for the others, chiefly because no method of attenuation of the viruses has been discovered. At the general meeting of the Keio Medical Society in November, 1920, Prof. S. Kusama made a very important report[1] on an experimental study of prophylactic inoculation against typhus with infected monkey's blood which had not been attenuated by passage through animal bodies or by any other means. By dilution of blood obtained from human typhus patients, injections were given causing no reaction in the animal bodies, but conferring a degree of active immunity upon the

STUDIES FROM THE ST. ANDREWS INSTITUTE OF CLINICAL RESEARCH.

III. A SCHEME FOR THE INVESTIGATION OF DISEASE IN CHILDHOOD.

BY ANDREW ROWAND, M.D. EDIN.

THE object of the St. Andrews Institute for Clinical Research is the investigation of disease in its earliest stages. It is unquestionable that many of the vague disabilities of later life, as well as many grave diseases, have their origin in childhood; it is therefore obvious that the study of children's ailments gives promise of being the most valuable part of our work. It is only the general practitioner who has the opportunity of watching the first manifestations of illness in childhood, and it is only by his observations that it will ever be possible to understand the prognostic significance of what are at present regarded as trifling ailments.

The Opportunities of the General Practitioner.

When I was starting work here I attended the out-patient department of a large children's hospital with the hope of observing the early symptoms of disease, but soon found that very little of the information I was seeking could there be obtained. I saw cases of advanced marasmus in infants, severe skin diseases, glandular swellings which had reached the stage where surgical interference was necessary, adenoids requiring immediate operation, mastoid abscesses, and so on. I was impressed by the great value of the work done and the skill displayed, but the vast majority of cases were end-results of disease which might surely have been prevented by earlier care. It must not be inferred that the general practitioner was to blame for this state of affairs; very probably many of the cases were not seen even by him till the necessity for prompt and skilled assistance had become obvious. It is impossible to-day to follow carefully the after-history of all children seen in the routine of busy general practice. A child suffers from a slight feverish attack of unknown nature and origin; a simple diaphoretic mixture is prescribed and the patient recovers quickly, it may or may not be by the aid of the medicine given. Similar attacks recur, and the doctor is not called in. Or a mild bronchitis is promptly relieved, and when succeeding attacks occur the mother repeats the mixture and all appears to go well. But the recurrence of such attacks may indicate some grave weakness, and when the doctor's services are next requisitioned a serious condition may be found.

Sir Robert Philip[1] states that in groups of Edinburgh school children examined at random 30 per cent. were found—after making full allowance for error and over-refinement of diagnosis—to show stigmata of tuberculosis, and he is of opinion that this is probably too low an estimate. Hamburger found that in post-mortem examinations—deducting those who actually died from tuberculosis—the frequency of lesions detected increased from 17 per cent. in those of 2 years of age to 53 per cent. in those between 11 and 14. Pottenger[2] makes the statement that probably 75 per cent. of all children have an infection before they reach the period of adolescence. Whether these statistics be accurate or not, they give good ground for the belief that many of the ill-defined feverish attacks in young children may be due to systemic intoxication resulting from bacillary invasion. Before school age the seed is very often sown, and, as Philip points out, the existing system of medical examination of school children is entirely misleading, as the returns refer only to obvious cases of disease. The slighter degrees of infection leading to systemic disturbance without definite physical signs can be studied only by the general practitioner. Tuberculosis has been taken as an illustration, partly because of its widespread and fatal nature, and partly because it is a subject to which we are giving special attention here, but what has been said about its early incidence applies to that of many other diseases.

Coöperation of Medical Practitioners.

A research into the early symptoms of disease, if it is to be of any value, involves the coöperation of many workers. No one individual can cover a wide enough field, and personal bias is apt to lead to the giving of undue prominence to a particular line of inquiry as the result of some preconceived idea of its importance. The value of evidence is more than multiplied by the number of observers. The circumstances in which we work here are ideal, for all the general practitioners in St. Andrews are giving their assistance. Similar coöperation will, no doubt, be possible in all centres when its importance has been fully realised; it is to the benefit of all, not only in widening the field of opportunity for study, but in lessening the possibility of misunderstandings. Our difficulty has not been to ensure coöperation among the general practitioners, but to determine the principles on which to base our work and to evolve a satisfactory scheme for carrying it out. An adequate scheme cannot be devised at once; false starts are inevitable, but they are of educative value. We may not even now be on the best road, but we appear at least to be going in the right direction.

The Problems of Tuberculosis.

It was decided that the investigation into the early symptoms of disease in children should have special reference to tuberculosis because of the outstanding importance of this subject. The activity of lymphoid tissue in the young and the frequency in them of tuberculous glandular infiltration naturally suggested to us a special study of this tissue and careful observation of all glandular enlargements. The importance of this line of investigation is generally recognised. Thus Philip[3] says: "If the more likely seats of lymphatic infiltration were scrupulously supervised in childhood and adolescence, the determination of tuberculosis at the lymphatic stage would be a common event. Persistent glandular enlargement in any area, however slight the degree of enlargement, should not be passed over lightly." Pottenger[2] says: "Recognition of early lymphatic tuberculosis is the key to the tuberculous problem."

The Nature and Functions of Lymphoid Tissues.

Accordingly we undertook a preliminary study regarding the function of lymphoid tissue and the nature and development of lymphatic glands. We were met on the threshold by rather striking and unexpected difficulties, for the whole subject has been much less fully studied than one would naturally have assumed to be the case. Presumably from its activity in the young lymphoid tissue has some peculiar function. It is commonly supposed to be protective before the body cells generally have acquired a power of resistance to bacterial infection; its needless sacrifice should therefore be avoided. It is, indeed, not easy to understand how the lymphoid tissue situated in the mucous membrane itself and commonly called the "first line of defence" of the body can perform effectively the function of arresting bacteria that penetrate the surface, for it is not spread out in a continuous layer. Moreover, lymphocytes appear themselves to have the power of destroying the epithelial covering. Even when aggregated into masses, as in the pharyngeal and faucial tonsils, it would often appear—if judged from clinical experience alone—to be a source of weakness rather than of protection. The same may be said regarding the lymphoid tissue of the Eustachian tube—the "tube tonsil" as it has been named. The abundant lymphoid tissue of the vermiform appendix seems to be of very doubtful value, and it is the lymphoid tissue of the intestine which gives way to attack in typhoid fever.

Glands.

Glands are said to form the "second line of defence" of the body, and their protective function is generally assumed, but they frequently break down under the

III.—*Experiments with Smeared Virus.*

In this experiment the material used was a mixture of the blood and throat secretions of a scarlet fever patient. This patient, a young man of 22, had had measles and had been vaccinated; his general health had always been good. The present illness began on March 6th, 1921, with sudden shivers and fever; scarlet fever was diagnosed by a physician, and on the 8th patient entered the Kitasato Institute Hospital. On the 10th, when I collected the material, he had eruption all over the body, the tongue was coated pale white, the tip was a bright scarlet colour; temperature 37·4° C. The throat secretion was obtained after careful gargling, and the blood was taken from the median vein as in the previous cases. To determine the presence of the virus in the materials collected, the secretion was subcutaneously injected into monkey No. 148 and the blood into monkey No. 146. The former had fever of 40° C. on the 15th day, lasting for five days; the latter had fever on the 7th day, rising on the 10th day to 39° C. with eruption over the face, especially around the eyes. These symptoms agreed with those of experimental scarlet fever in man.

Throat secretion and blood were mixed and a cotton pledget, soaked in the mixture, was carefully smeared over the mucous membrane of the tonsils and throats of the children who had received prophylactic inoculation. As virus smeared over the mucous membrane was liable to carry infection to others, the two oldest children, who were attending school, and the youngest, who was still at the breast, were excluded from this experiment; only the boy I. and the girl H. received the smeared material. For the next three weeks I carefully examined the temperatures, urine, and throats of the children, but there was nothing to be noted at all. Thus the inoculation completely protected the children from the disease.

IV.—*Summary.*

From the foregoing experiments it is clear that prophylactic inoculation against scarlet fever with the blood of a patient, taken before the eruption appears and given subcutaneously in an amount of 0·0001 c.cm., causes not only no local or general symptoms in man, but protects him from infection. Even an injection given 50 days after inoculation with the blood, and smearing the children's throats with the mixture described above, 115 days after inoculation, did not give rise to the disease.

It has been claimed by some investigators that one-third of human beings have a natural immunity against scarlet fever, and perhaps my children had this natural immunity. Moreover, it has not yet been determined that the dose of blood given in the infection experiments was enough to infect the children. Taking these facts into consideration, I cannot claim that these experiments are flawless; but considering the results which Dr. Kusama obtained with typhus fever, the fact that the experimental objects were of the most susceptible age, and the fact that the control monkeys showed the presence of the virus in the material used for the smearing, it is not an overstatement to say that the experiment strongly suggested the efficiency of prophylactic inoculation against scarlet fever.

On the effective period of immunity and its time of appearance after inoculation will be reported later.

My thanks are due to Dr. Kusama, who has given me valuable guidance, and to Dr. Karube, Dr. Sukekawa, and Dr. Miyajima, who have greatly assisted me.

LITERARY INTELLIGENCE.—The twelfth edition of Bruce and Dilling's "Materia Medica and Therapeutics" is announced for immediate publication by Messrs. Cassell.—Messrs. J. and A. Churchill have just issued a 48-page catalogue of medical and scientific publications. The forthcoming appearance is announced of "An Introduction to Biophysics" by Dr. D. Burns, Grieve Lecturer in Physiological Chemistry at the University of Glasgow, with an introduction by Prof. D. Noel Paton, F.R.S. The subjects dealt with include energetics, cellular mechanics, cell communities, transport, and the organism as a whole.

X RAY TREATMENT OF TWO CASES OF OTOSCLEROSIS.

BY J. H. DOUGLAS WEBSTER, M.D. EDIN., M.R.C.P. EDIN.,

PHYSICIAN IN CHARGE OF THE PHYSICAL MEDICINE DEPARTMENT, MIDDLESEX HOSPITAL, LONDON; LATE HON. RADIOLOGIST, MANCHESTER EAR HOSPITAL.

IN dealing with otosclerosis we are "confronted with one of the most difficult and obscure problems in modern medicine" (Gray). And because its ætiology and essential nature are still largely unknown or in dispute, and its course one prolonged usually over so many years (often with intermissions or natural arrest), to make an estimate of the true value or otherwise of any treatment is a matter of the greatest difficulty. In well-established cases, which are perhaps the great majority of those presenting themselves, permanent bony damage has already taken place at the stapes-foot, with possibly secondary nerve impairment, and such cases afford no fair test of the value of radiation treatment, any more than late inoperable malignancies, old-standing exophthalmic goitres or (as I have noted) acromegalics. It is only in the earliest stages when there are young actively proliferating or hyper-functioning cells that radiation can be expected to benefit to a satisfactory degree. Now, unfortunately, as Brühl says, otosclerotic patients rarely notice the earlier tinnitus or slight impairment of hearing, and therefore do not usually apply for advice till the newly-built bone at the annular ligament of the oval window has reduced the hearing to a marked degree (whispering reduced to 0·5 m. or less). This being so, there is nothing to be wondered at that some otologists hold the view, and frankly tell their patients, that it is an "incurable" complaint.

Prof. Siebenmann, the eminent oto-laryngologist at Bâle, has been experimenting since 1912 with radiation treatment, encouraged, at the beginning, with the good results obtained by radiation of an ostitis fibrosa case (as he remarked at the Oto-laryngological Congress at Kiel in May, 1914), and while awaiting an analytical report from him on the results of his many hundred cases, it may be of interest to bring the matter forward, discuss the rational basis for the treatment, and give the results of two cases treated.

Theories as to the Cause and Nature of the Disease.

There are about ten distinct theories as to the cause and nature of the disease. The earliest opinion was that it is secondary to middle-ear inflammation (of mucous membrane or periosteum); later views are that it is a primary condition, either a bone disease or an abnormal development of the cartilaginous remnants in the labyrinth capsule, or is due to vascular conditions (active hyperæmia, anæmia, and venous congestion each having supporters). Then there are toxic and bacteriological, internal secretion, and chemical theories; and there is the nervous theory, that the sometimes associated degeneration of the labyrinth nerve is primary, and the bone change secondary to this; and the developmental theory, that there is arrested development or degeneration of the organ of hearing as a whole, central and peripheral. There seems no doubt that many factors can excite its appearance in a predisposed person. Brühl, in this connexion, gives authorities for syphilis, arteriosclerosis, chills, internal secretion changes, latent tetany, rheumatism and gout, uræmic intoxication, scrofula, anæmia, rickets, osteomalacia, auto-intoxications, tuberculosis, tropho-neurosis, and wasting diseases. The hereditary nature is most marked, as with bony abnormalities (polydactylism, multiple exostoses, &c.) and some bone diseases (Paget's disease, achondroplasia).

Katz was the first (1890) to publish the microscopic findings in a case diagnosed during life as a stapes-ankylosis. Toynbee (1860) and Tröltsch (1881) had called the condition "sclerosis," and for long it was are immune to bovine infections for the rest of life. Brownlee,[10] in a statistical inquiry published by the Medical Research Council, concludes that in districts where infection by milk is prevalent in childhood the "young adult" type of phthisis is rare. Bushnell,[11] agreeing with Calmette, holds that the time has now come when we must strive to substitute an artificial premeditated infection for the present infection by chance, though he admits that we have not sufficient knowledge to justify the attempt in the meantime. All children will in the future be vaccinated for tuberculosis.

Even now Shiga[6] advises that preventive inoculation with his Tb. serovaccine should be undertaken during the school age, and considers the following cases suitable for treatment: (1) those who have been exposed to infection within their family circle; (2) those of consumptive appearance, as, for example, the anæmic and debilitated, and those of weakly constitution; (3) those with chronic tonsillitis or chronic cervical adenitis; (4) those who easily catch colds and have a continuous slight fever; (5) those who from time to time suffer from slight fever of uncertain origin, or whose temperature rises slightly after moderate exercise; (6) those, finally, in whom rough or diminished breath sounds are found on auscultation. He regards von Pirquet's reaction as a necessary preliminary to inoculation, and considers a marked reaction as a favourable indication for vaccinotherapy.

The Scope of the St. Andrews Scheme.

It became evident to us that even if the inquiry were concerned solely with the investigation of tuberculosis its scope must be very wide. All symptoms indicative of toxæmia must be included, and though there appears to be a great similarity in these symptoms whatever may be the nature of the toxin, it is probable that the differences are quite distinguishable if we were trained to observe them; only by the study of such vague and indeterminate symptoms can the earliest onset of any disease ever be detected. No pre-supposition as to the probable outcome must bias observation the inquiry must include all children, of all types and in all circumstances, who show the earliest symptoms of departure from health. It is impossible to isolate any clinical investigation so as to deal with the origin and onset of tuberculosis alone.

It may be said that to obtain sufficient material for investigation a wider field than St. Andrews is necessary. Experience has already proved the contrary. Complete and methodical examination of a limited number of cases is worth much more than incomplete investigation of a very large number. To keep in touch with all our cases and to analyse our records is already a very heavy task. The suitability of St. Andrews for our work was emphasised by Sir James Mackenzie when the Institute was projected; all classes of the community are represented and the population is not migratory. The material is ample for the members of our staff, and we have been compelled to give up, in the meantime, any idea of linking up a larger district by the aid of outside practitioners.

The ideal at which we aim is to obtain records from birth onwards of all St. Andrews children—all children of all classes. No similar attempt has ever been made. If the investigation were made among children of the poor alone it would not be of anything like the same value. Surroundings undoubtedly play a great part in the causation of disease, but how great a part can never be known if statistics are confined to one class only in a community. Even such diseases as marasmus and rickets are not confined to the poor; faulty dieting is common enough among the well-to-do. Moreover, rickets occurs in circumstances which make it difficult to believe that it is essentially a deficiency disease due to the lack of an antirachitic factor in milk-fat. This may be the main factor in most cases, but other factors must be considered, especially the absence of fresh air and of cleanliness. The investigations of Noël Paton[12] and his collaborators in Glasgow [illegible]d attention to their importance. In young dogs under ordinary laboratory conditions a liberal allowance of milk-fat neither prevents the onset of rickets nor cures it when it has developed. Cubic space is important in a house, but the mere calculation of cubic space may not lead us to the chief element at fault in the surroundings; there is more in a mother's management of a family than is generally realised. It is possible to find a large number of healthy children in a poor and crowded house and a few weaklings in a mansion.

The Methods of the Scheme.

In order to make our records complete it is necessary to have the coöperation of all the doctors and nurses, and, what is equally important, the intelligent coöperation of the parents. All the practitioners of St. Andrews are on the staff of the Institute, and through them we ensure the help of the nurses. The main difficulty is to get the help of the parents, but it is lessened by the fact that each mother deals directly with her own doctor only; there is no inspection by an official doctor and no suspicion of any outside interference. This is a most important matter, for the poor have a perfect right to resent what would not be tolerated by the well-to-do. Children brought to the Institute are examined by the family attendant himself, or jointly by him and some other member of the staff who is present by his request, and with the consent of the parents. When the cases are read at the weekly meetings they are numbered, not named. Our methods bear no resemblance to those of a hospital out-patient department. The fact that we have acquired the confidence of the community is shown by the number of our cases.

Coöperation of Parents: Weight Charts and Child-welfare Centre.

The real difficulty is to ensure that the mother will call in the doctor when the child begins to show the first symptoms of illness. We have endeavoured to get over this difficulty in connexion with infants under one year by distributing weight charts through the doctors and nurses, and by impressing on the mothers that regular weekly weighing of the baby is necessary in order to detect those early signs of failure of nutrition which call for a doctor's services. They are appreciating this and showing interest in the weekly records. The doctor or nurse takes the weight at birth, a handy spring balance being now part of the equipment of each doctor's bag. The nurse who will be in charge of the child-welfare centre is at present giving us much assistance in cases where want of intelligence or carelessness on the part of the mothers might lead to faulty or incomplete returns. When the child-welfare centre is in full working order we shall have much assistance from the work done there, for though we do not consider it advisable that the Institute should be regarded as having any direct control in the matter of its management and the nature of the treatment prescribed, the physician in charge, being one of the local practitioners, will necessarily be a member of our staff. The weight chart is of handy form, and is spaced for 52 weeks. At the side and on the back is sufficient room for short notes made by the doctor or nurse from time to time.

Examination of Infants: The Infant's Card.

We have drawn up cards containing a number of queries with regard to infants which the doctors will fill up in all cases. It is necessary to ensure uniformity in the observations made; whether the items selected are the most suitable can only be determined after further experience. The value of many at least of the queries is sufficiently obvious; for example, the weight at birth, whether or not the child is premature, and whether it presents any abnormality. It would have been well to leave a space for description of the nature of the confinement; it would be interesting to know whether the alarming condition of the baby sometimes seen after the employment of "twilight sleep" has any prejudicial effect on its subsequent doses have been worked out, and the total dose advisable for each ear has been the subject of investigation. A certain amount of hair-fall takes place, temporary only, but no deleterious effects have been noticed on the labyrinth, dura, brain, hypophysis, or in other ways. Coolidge or Müller's boiling tubes are used. (I should be glad to give fuller details of the technique to any interested who write to me.) During a visit to Bâle Prof. Siebenmann kindly gave me fully his views as to the theoretical grounds for the treatment, and explained that he advises it in late cases with the hope of arresting the process at the stage it is in, and in early cases with the hope, and in fortunate cases with the result, not only of arresting it, but of causing some slight improvement. No more, considering the pathology of the condition, can be hoped for. It might be of use in certain cases to combine ovarian radiation with the ear radiation (*see* Wetterer on beneficial results with ovarian irradiation in osteomalacia). In a recent communication (June 16th, 1921), Siebenmann writes that "his trial of the method has not continued long enough for him to come to a definite conclusion on the matter"; he began "with a good dose of optimism," but the results "are only to a small degree positively encouraging." As a number of radiation schemes have been used, and these only in the last four years to any considerable extent, it is still too early to hope for much in the way of results. But the method seems to deserve full investigation, as even if the treatment only arrests the usually inevitable progress of this common and disabling complaint (perhaps even only in certain types of cases, as may be defined by further research on the subject), it will have achieved a great therapeutic success in a region which hitherto has been, for the most part, a despair of the internist and the otologist, and, as a result, a "happy hunting ground" for the quack in various forms and disguises.

The Author's Cases.

My two cases are as follows:—

CASE 1.—Mr. F., aged 37, no hereditary history, R. ear began to be affected 15 years ago, L. ear about 10 years ago, had consulted many of the leading otologists in England, and tried pneumo-massage, &c., had been told it was almost certain to progress slowly and was incurable. On a visit to Switzerland, in the spring of 1920, with the hope that the high dry air for some months might effect some improvement, he consulted Prof. Siebenmann, who recommended X ray treatment as the only thing likely to arrest the course of the disease. Recommended to me by a medical friend of his. Being very sceptical as to possible benefit, I made a visit to Bâle, after some correspondence with Prof. Siebenmann, largely also to choose between the various schemes of radiation employed. The patient understood that the most that could be hoped for was arrest, which he greatly desired, as his wife said he was worse than he was six or eight months ago, and any further increase in his deafness would cut him off completely from social enjoyments. Tympani were normal, no operations had been performed (though one had been recommended in the nose), whispering heard at the ear only, R. ear with C fork, Rinné −12, L. ear −7. After the treatment, as anticipated, there has not been any change whatever to remark on; the watch was heard, if anything, slightly further away on the left side than before (from 1–1¼ in.). So far the condition seems stationary, both as regards hearing and tinnitus. It will require another year or two to show if it is progressive.

CASE 2.—Miss H., aged 25, no hereditary history was made out, but a brother and a sister show signs of the disease coming on. No operations, but a history of nasal catarrh. She was referred to me by Dr. J. W. Stenhouse, and as she was attending the Ear Hospital, under Dr. Frank Wrigley, he kindly saw her before I began treatment, and wrote that as "he was quite sure she was not going to improve with the ordinary methods of treatment, it would be quite worth while to try X rays." He viewed her as a mixed oto-sclerosis and catarrhal case. R. ear began about eight years ago, left not until about seven months ago, since when it had become rapidly worse, and she was in danger of losing her employment (office work). Marked tinnitus both low and high. Paracusis Willisii. Watch at R. ear at ½ in., L. ear about 1 in. R. ear, Rinné −6; L. ear, Rinné −6. After treatment over three months she had distinctly improved, could hear a clock at her home that she had not heard for eight months, the low-toned tinnitus in the left ear was much less, and was away for considerable periods (Ortloff's fifth case showed improvement in the low tinnitus—? vascular, of hyperæmic origin, Mayer, Brühl, &c.), and Dr. Wrigley, examining her on April 30th, found definite improvement on both sides; she could hear his watch (a softly-ticking one), which she had not previously been able to do. Treatment was continued, and the improvement maintained. On June 16th the watch was heard at R. ½ in., the L. 1¼ in. In letter of August 15th the improvement was reported as continuing, "can still hear the clock." It is hoped that this slight but definite improvement will be maintained, and in any case that the process has been arrested, as Siebenmann finds is sometimes apparently the case.

My thanks are due to Sir William Milligan and Dr. Frank Wrigley for their interest and encouragement, and to Prof. Siebenmann for his kindness and patience in correspondence and on my visit to his clinic, and to Dr. Löffler and the sister-in-charge of the Rontgen work at the Physical Treatment Department of the Bürger-Spital, Bâle, for their kindness in giving me details as to the method of treatment.

never been satisfactorily investigated. With regard to diet, it is manifestly impossible to calculate the calories in the daily diet of individual children whose food is not accurately estimated at every meal. The digestive organs of normal children can deal within reasonable limits with many varieties of diet.

What we aim at recording is the manifest excess or privation of the various elements considered necessary in all diets, and to note the types of diet in common use among children of the various classes of the community, and to compare their apparent results. In noting failure of nutrition we observe the want of muscle substance and loss of muscle tone. "Tuberculosis toxins would seem to act specially on neuromuscular structures. The dystrophic influence is seen in the progressive loss of sarcous substance and associated enfeeblement and irritability of muscle. Hence early manifestation of motor weakness, both of limbs and of viscera—the feeling of tiredness, the disinclination for effort, the softening of pulse, and the gastro-intestinal sluggishness. These are generally in evidence long before cough or expectoration or other indication of local lesion is forthcoming ...... loss of muscle counts in tuberculous intoxication rather than loss of fat. Patients with advanced tuberculous intoxication may have abundance of adipose tissue" (Philip[3]).

It is with the object of testing such statements and of finding out whether or not they form any guide to the differentiation of tuberculous from other toxins that we draw attention to them in the investigation of failure of nutrition. Sir James Mackenzie has clearly demonstrated the existence of muscular rigidity in connexion with underlying visceral disease and its value in diagnosis. Pottenger[2] affirms that in tuberculous disease of the lungs muscular rigidity may be detected. The spasm, he says, varies in position with the lesion; if in front, the sternomastoid, scaleni, pectorals, and intercostals are affected; if behind, the trapezius, levator anguli scapulæ, and rhomboidei. So far we have not found this borne out in our examination of early cases of phthisis, but it is well to bear the statement in mind and to continue to test its worth. Exhaustion is always a sign that a child is not well. Already we know that there are various types of exhaustion, possibly distinctive of different toxæmias. Another hopeful field is the investigation of anæmias. It is quite impossible to estimate the severity of an anæmia by the appearance of the patient, or even in many cases to determine whether or not anæmia is present. Therefore in all cases in which pallor is a symptom we are having blood examinations made at the Institute. If time permitted of this, we believe that valuable information might be obtained by the routine examination of blood in all cases of illness in children. Something distinctive in the way of blood pictures might be found in connexion with the onset of various diseases. It is unnecessary to insist on the necessity for observing irregularities of temperature which may be slight and therefore overlooked. The condition of the pulse must be carefully observed in all its aspects. Rapidity and softening, by which is meant loss of tone with apparent fullness of the artery and feeble impulse communicated to the examining finger, are always suggestive of an active toxæmia. X ray examination of the chest is made in all children with glandular enlargement, with the object of observing, as far as may be possible, the condition of the mediastinal glands and the state of the lungs. We are also examining the chests of a number of healthy children; without a knowledge of varieties in the normal, which have not yet been sufficiently investigated, it is impossible to recognise and interpret the abnormal. Urine examinations of a somewhat more elaborate nature than is possible in every-day practice are made in the chemical laboratory in all cases of failure of nutrition.

A CASE OF
POISONING BY CANTHARIDIN.

BY C. H. ANDREWES, M.B., B.S. LOND.,
HOUSE PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

THE following case of poisoning by cantharidin, the active principle of cantharides, seems worth recording, as it may help to throw a little light on inflammations of the kidney. I can find no record of any other case in which cantharidin itself has been taken.

At about 4 P.M. on June 7th, 1921, a medical student tasted, out of misplaced curiosity, some crystals of cantharidin; no unpleasant taste was noticed. He stated that he took as much as would go on a pin's head—almost certainly at least one-fiftieth of a grain. As tincture of cantharides contains only 0·01 per cent. of cantharidin, this would be the equivalent of about 220 minims of tincture of cantharides, or over 40 times the maximum pharmacopœial dose. Shortly afterwards the patient had tea, including some bread and butter. About 7 P.M. he noticed pain in the left lumbar region, shooting round to the front, but not very severe. A few hours later he felt much slighter pain in the right lumbar region. At 8 P.M. he began to pass urine in small quantities about every quarter of an hour; there was some pain on micturition. At 9 P.M. he began to feel unwell and noticed blood in his urine; this increased in quantity later. During the night he micturated only five or six times and obtained some sleep. About 3 A.M. next day he vomited twice. In the morning he came to St. Bartholomew's Hospital and was admitted to the wards; he was then passing urine containing blood about every two hours, and he still complained of lumbar pain, mainly on the left side.

On admission he looked pale and rather anxious; his mouth and tongue were not at all blistered. Nothing abnormal was discovered in his chest, his blood pressure was 125 mm. Hg (systolic) and 80 mm. (diastolic). There was tenderness on deep palpation in the left lumbar region; no œdema anywhere. His temperature was 99·6°F., his pulse 120, his respirations 24. He gave no history pointing to previous nephritis; he had never, to his knowledge, had scarlet fever. The urine was red in colour and acid; it contained 0·64 per cent. albumin (Aufrecht), large numbers of red blood cells, and no more leucocytes than could be accounted for by the amount of blood present; no casts or epithelial cells were seen.

On the 9th the patient's condition had improved; his pain was less. 53 oz. of urine were passed (intake 84 oz.). There was still much blood, but polymorphonuclear leucocytes were nearly as numerous as red cells. Two red-cell casts were seen, but no other casts. His temperature was down to normal; he passed a dark green stool, which was negative to benzidine. On the 10th he passed 27 oz. urine (intake 50 oz.). On the 11th he looked less well and passed only 20 oz. (intake 68 oz.). This still contained much blood and a few red and white celled casts; the albumin was 0·1 per cent.

The patient's condition then began to clear up rapidly. By the 13th he was passing 43 oz. of urine, which contained no blood microscopically (intake 70 oz.). There was only a faint haze of albumin. By the 15th no albumin could be detected. In the centrifuged deposit three red cells were seen, fair numbers of leucocytes and many casts, mostly hyaline, a few epithelial and granular. By the 20th no red cells and no casts could be found, and only a few leucocytes. Throughout the course there was no headache, no mental symptoms.

assault of germs and themselves become foci of disease. They may be physiologically enlarged as the result of protective activity, or pathologically enlarged to the detriment of the organism. It is no easy matter to distinguish these separate conditions. The whole problem of glands is a very intricate one, and many puzzling questions remain unanswered. For example, is a palpable gland in the neck an enlarged gland, and at what stage in infancy do normal glands become palpable in any situation? To what extent do glands vary in number and size in healthy individuals? Are new glands formed on comparatively slight stimulus, and do they disappear entirely when the stimulus is withdrawn? The necessary elements for their development are present in any loose connective tissue. Gulland[4] states that glands which have been removed are very readily replaced and that the newly formed glands are not distinguishable from the original ones after some time. Even the relationship between glands in various situations is not definitely established. Some observers[5] have maintained that the tubercle bacillus may enter through some part of the mouth or pharynx, possibly through a decayed tooth or through the tonsil, and track from gland to gland down to the root of the neck until the lung itself is affected by direct contact with a caseous gland; this has been given as an explanation of the occurrence of tuberculous infection of the apices. Woodhead and other observers believe that there is a direct lymphatic connexion between the deep cervical and bronchial glands, and that the tubercle bacillus may thus pass from the pharyngeal mucous membrane to the lungs. Shiga[6] states that tubercle bacilli, having reached the respiratory passages, are taken up by the leucocytes, pass through the mucosa into the lymphatics, and eventually reach the hilus glands by way of the glands of the neck. According to Still,[13] "direct extension of tuberculosis from cervical glands to those in the mediastinum, if it occurs at all, is extremely rare. Enlargement and caseation is progressively less in cervical glands from above downwards (affected from tonsil), but when mediastinal glands are affected in such cases they show as advanced changes as the upper cervical glands. Hence the latter were probably infected in the usual way through the lung." According to Cobbett,[5] "careful investigations of unselected material provided by children dying in general hospitals have shown that the bronchial glands are affected with tuberculosis, or tubercle bacilli, much more commonly than the cervical or mesenteric glands, and there, therefore, can no longer be any doubt that the lungs, even in young children, are a commoner portal of entry of tubercle bacilli in general than the intestine or pharynx." He states, further, that investigations have shown that it requires much larger doses to infect when the bacilli are swallowed than when they are inhaled. In animals the lungs present a marked contrast to other organs, in that they invariably yield copious cultures of bacteria, including moulds, &c.; and that these bacteria really get into the lungs with the inspired air there can be no doubt. The tissues and fluids of the healthy body, lungs excepted, are almost entirely free from living bacteria.

Calmette's[7] view is very different. Too much emphasis, he believes, has been laid on the respiratory route. Germs floating in the air are not often sufficiently numerous to be carried into the fine bronchial ramifications, the filtering action of the nasal and buccal mucous membranes being very effective; moreover, very small droplets do not as a rule contain bacilli, and numerous researches have shown that healthy lungs are nearly always aseptic. Most tuberculosis, from that of infants to that which occurs in adults, is derived from penetration of the intestine. The digestive tract is the principal path of invasion by the human as well as by the bovine bacillus.

With regard to the condition of lymphatic glands as an indication of the point of entrance, contrast the views of these two authors. According to Cobbett,[8] "if the lymph glands are such efficient filters as we have reason to believe, it seems probable that they will seldom, if ever, let a tubercle bacillus through their meshes without retaining in their substance a number of others sufficient to cause disease there and produce obvious lesions which will serve to mark the path along which the invaders penetrated into the body." According to Calmette, Cohnheim's law, which states that a cellular reaction always marks the site of invasion, is only true of individuals already infected. Unless this condition is fulfilled, or the dose of infection is truly massive, no cellular reaction indicates the presence of bacilli within a gland. Von Behring was the first to maintain the intestinal origin of pulmonary tuberculosis. Tubercle bacilli, he said, received in infancy may pass through the wall of the intestine and through the mesenteric glands, and so reach the lungs, without leaving any lesion in the abdominal cavity.

The recent work of Ferrán and Chabás is of interest in this connexion. They maintain that "even under laboratory conditions, when healthy animals are housed along with infected animals in cages whose walls and floors as well as the food are thickly smeared with living tubercle bacilli, tuberculosis will not occur in the uninfected unless they are permitted to drink water contaminated with their own excrement. Ferrán concludes from this that the tubercle bacillus is merely the end product or transmutation of an intestinal saprophyte, and that infection need not be feared as long as the tubercle bacillus is the only organism present" (Sorley[8]).

Conjoint Clinical and Laboratory Investigation.

An investigation has been undertaken in the bacteriological laboratory of the Institute and in the physiological laboratory of the University with the object of obtaining more accurate information regarding the reactions of lymphoid tissue to tuberculous infection, the power of resistance of the lymphocytes, and the course and extent of possible spread of infection by the lymphatics before there is general infection of the blood stream. From the clinical side we are carefully observing all glandular enlargements and co-relating them with the possible portals of entry of infection, and by prolonged study endeavouring to arrive at some conclusion regarding the nature of the infection in each case. There is a tendency at present to regard all glandular enlargements as evidence of tuberculosis, yet many of them disappear and leave no sign to support the view that they were associated with this disease. It is surely of importance to determine in what proportion of cases this is found to occur. These diverse views show how confused and inadequate our knowledge of the disease really is.

Prognosis and Treatment in Tuberculosis.

Preventive and curative treatment have as yet no sure basis, and our powers of prognosis are very feeble. Rational prognosis cannot be based on theories, however plausible. It can only be based on observation of facts. The present tendency is to base all our hopes on inoculation. Hereditary predisposition is now regarded as resulting merely from some special texture of the cutaneous and lymphatic apparatus, and not from the presence or absence of a specific hereditary impregnation with the bacillary products. Special stress is laid on the presence or absence of acquired immunity. Few individuals, it would appear, can hope to escape infection, and the slight infections to which we are all exposed in childhood may provide us with the power of resistance to later and more deadly attacks. In the opinion of Lyle Cummins[14] this conception of "infection and resistance" provides the master key to the whole question of tuberculosis.

Nathan Raw[9] believes that bovine and human tubercle will not live in the body at the same time, and that the one disease produces immunity from the other. He states that a child who develops primary abdominal tuberculosis with involvement of the mesenteric glands, or an infection of the neck glands, which are usually caused by the bovine bacillus in milk, is immune to infection by the human bacillus for the remainder of life, and that young adults attacked by the human bacillus, producing primary pulmonary tuberculosis, and with the discovery of secretin by Bayliss and Starling.

The deeper insight into the mechanism of the function of the cell given by Prof. Moore cannot fail to be of benefit to mature workers. Whether students will be able to appreciate this presentation of the subject must depend upon their previous scientific equipment.

BRIGHT'S DISEASE.

Praxis der Nierenkrankheiten. By Prof. L. LICHTWITZ, Altona. (Fachbücher für Ärzte. Vol. VIII.) Berlin: Julius Springer. 1921. With 33 illustrations. Pp. 252. M.45.

IN this monograph Prof. Lichtwitz establishes his position among the leading continental authorities on diseases of the kidneys; it is not only a guide to a subject of considerable difficulty, but it is also an exposition of the author's own point of view based on his personal experience. The subject is approached along orthodox lines, and in the opening pages a summary is given of the main principles on which other workers have attempted to base their classification of diseases of the kidneys. In its main outline Prof. Lichtwitz's classification follows that of Volhard and Fahr; at the same time he accepts Aufrecht's point of view in emphasising for classification purposes the importance of the primary site of the disease process in the kidney. The anatomy of the kidney is shortly reviewed and its physiology is well summarised in its relation to medicine.

The best and most important section of the book deals with the crucial signs of kidney disease. The author's critical remarks on the significance of albuminuria, cylinduria, red and white blood corpuscles and epithelial cells in urinary deposits are worthy of the closest study and attention. In the functional tests of renal efficiency Lichtwitz makes a sharp distinction between the secretory and concentrating power of the kidney, since these functions are performed by different parts of the renal epithelium. He gives a standard renal-test diet, to which on successive days ¾ litre of water, 10 g. sodium chloride, and 20 g. urea are added. The urine passed during the day, from 8 A.M. to 8 P.M., is collected in two-hourly periods; the urine passed during the night is collected together and makes the seventh specimen of the 24 hours. For practical purposes it is sufficient to measure the volume and specific gravity of the separate specimens, and to estimate the urea and sodium chloride only in the total quantity of the 24-hour period. A table is given by which the amount of salt and urea output may be roughly calculated from these simple data. Prof. Lichtwitz would limit the use of the term renal insufficiency to disturbance of the power of concentration. Renal insufficiency always leads to an increase in the non-protein nitrogen in the blood and tissues. Non-protein nitrogen retention is an important sign in diagnosis and as an index of the course of the disease, but it is not proportional to the degree of renal damage and cannot, as Volhard has suggested, be used as an index of comparison between different cases.

The extra-renal signs of Bright's disease (incorrectly termed "Die Nierenfolgen"), namely—œdema, raised blood pressure, cardiac hypertrophy, arterio-sclerosis, uræmia and anæmia—are perhaps too theoretically discussed for a practical book. The author accepts a twofold relation of raised blood pressure to kidney disease; on the one hand he speaks of the association of nephritis with raised blood pressure, and on the other he recognises the sequence of: raised blood pressure—arterio-sclerosis—renal sclerosis. In the description of the clinical types the morbid anatomy and histology are briefly stated, more attention being given to the ætiological aspect. Nephrosis (or toxæmic kidney) is dealt with in detail and the "Genuine Schrumpfniere" (primary granular kidney) is [illegible] ther briefly. In general, however, the clinical aspect is carefully and ably reviewed from the present-day standpoint.

The book is a masterly introduction to the newer pathology and treatment of diseases of the kidney. It has throughout a practical interest that ensures it the widest recognition.

ALFRED NEWTON.

Life of Alfred Newton, Professor of Comparative Anatomy, Cambridge University, 1866–1907. By A. F. R. WOLLASTON. With a Preface by Sir ARCHIBALD GEIKIE, O.M. London: John Murray. 1921. Pp. 332. 18s.

THIS is a delightful book about a man who was also delightful in many ways. In his obstinacy, his hatred of any change, his whole-hearted aversion towards publishers, reviewers, popular natural history publications and their writers, his kindliness, his love of work and meticulous accuracy, he must in many ways have resembled Samuel Johnson, and another whimsical and very real naturalist, Charles Waterton. Though nominally a comparative anatomist, Prof. Newton's actual position in the scientific world was that of an ornithologist, and to the study of ornithology he devoted his life. It was in 1865 that the University decided that the study of comparative anatomy should be removed from the school of the professor of anatomy and should be combined with a professorship of zoology, the two making a new chair. The first election took place in 1866, the candidates being W. H. D. Drosier, M.D., of Caius, and Alfred Newton, M.A., of Magdalene, the latter being successful. Newton had previously been well known for researches in ornithology; for six years after his matriculation in 1848 he was elected to the Norfolk Travelling Fellowship, whereby he was able to make ornithological journeys in Lapland, Iceland, the United States, and the West Indies. He was much interested in the question of the extinction of birds, and with infinite labour collected notes and information about the great auk or gare fowl and the great bustard, with the intent to write two books, "The Story of the Gare Fowl" and "The Bustard in Britain." But his passion for accuracy and completeness made him dissatisfied with his material, and neither book arrived at publication. Incidentally we may mention that Mr. Wollaston says that it was Newton's inquiries into the matter of the great auk which led Kingsley to refer to that ancient bird in "The Water Babies." Part of Newton's duties as professor was to give courses of lectures in zoology, but he was never happy as a lecturer, and, as he himself says, knew that he was one of the worst of lecturers, but he devoted himself with great ardour to the museum, and was always on the look-out for specimens to add.

One of the most interesting portions of the book is that dealing with Newton's views as to other ornithologists and naturalists. "Two of a trade never agree," says the proverb, a sentiment which is as old as Hesiod, and Newton's remarks about Gould, Buckland, who was "wanting in every essential of a naturalist, except zeal," and Seebohm are just as good reading as Waterton's remarks upon Swainson and Audubon, but both Newton and Waterton were in the right. Mr. A. C. Benson's description of the trials which Newton underwent when music was introduced into Magdalene College Chapel, together with a collect from the office of Compline raises a smile, and his agonies when an ibis with a scarlet head appeared among the Chorus of Aristophanes's *Birds* are described with great vividness. In 1907 he died, and Mr. Wollaston gives us his almost last letter, written to his friend Mr. Harvie Brown (p. 291), a letter which in its modesty, its thankfulness for a happy life, and the gift of friendships sums up the whole man. He was, to use Sir A. Geikie's words, "one of the most eminent ornithologists of his day," and his Dictionary of Birds is a monument of industry and knowledge.

progress. The length is of importance, and should be taken from time to time, as the ratio between growth and weight is a fairly constant one in normal conditions. Any ill-health of the parents and of other children is noted, and the existence of any tuberculous heredity on either side. We classify surroundings as good, fair, and bad. This is vague, but much must be considered in addition to number of rooms and cubic space; general evidence of good management may rightly modify our opinion of a small house. We leave it open to the doctor to judge of all the circumstances before coming to a decision. I have recently seen a large family in two small rooms in a dilapidated house who were all fairly healthy. If I had found them all showing such signs of disease as rickets and enlarged glands the cause would have been regarded as perfectly obvious. Discovery of good health in a bad house is as valuable an observation as the discovery of disease, but is apt to make much less impression on the mind. Efforts by the parents to make the best of bad circumstances by good management may be much more successful than is generally considered to be possible.

If the child is not breast-fed the nature of the substitutes is noted and the dates at which they were given. It is unnecessary to point out how impossible it often is to find out exactly what some mothers are giving to their children. If unsterilised cow's milk is given we note the source of the milk; it is our intention to have bacteriological examinations made at the laboratory from time to time, and also to have the mother's milk analysed in cases where it is suspected to be of poor quality. In the consideration of gastro-intestinal disturbances in infants and children it is of the utmost importance to consider all associated symptoms with great care. The disturbance may not be due to an error in diet at all; the diet may be not theoretically perfect, yet of a kind which we have known to suit many other children. The disturbance may be purely reflex, and the primary mischief may not be in the stomach or intestine at all. The symptoms of a pulmonary catarrh may be overlooked because of the prominence in the picture of the secondary gastro-intestinal symptoms. Meticulous tinkering with the diet will not carry one far in such cases. Want of rest and excitement, due to the fussy attentions of a mother or nurse, may upset a child's digestive system. We know that excitement may cause diarrhœa in an adult, and worry may bring the functions of the digestive system almost to a standstill. The diverse views on the value of many foods—apart from gross errors—indicates that the solution does not lie entirely in percentage proportions and calories.

We consider it highly important to note the time and circumstances of the earliest onset of various common ailments, and have selected for special observation catarrhs (respiratory and gastro-intestinal), nasal obstruction, ear trouble, and glandular enlargement. A short account of any special illness can be given on the back of the card. By means of these cards and the weight charts we hope to obtain a fairly full record of the health of infants during the first year of life.

Details Recorded on Infant's Card.

Date, name, address, doctor.

(1) Weight at birth, (2) length, (3) mature or premature, (4) any abnormality, (5) health of parents, (6) any tuberculous heredity, (7) number and health of previous children, (8) surroundings (good, fair, bad), (9) breast-fed or not, (10) if not, what substitutes given and when, (11) source of milk-supply.

Onset of (12) catarrhs (respiratory and gastro-intestinal), glandular (13) nasal obstruction, (14) ear trouble, (14) enlargements, (15) any other ailment.

Notes of any special illness and after-history over-leaf.

Examination of Children: Children's Card.

We have prepared similar cards for the examination of older children. When a doctor is called in for any illness he notes the various points mentioned on the card quite apart from that special illness. It may be wondered how the doctor will obtain opportunity of seeing children between infancy and school age unless he is called in on the occasion of serious illness; we hope that with the opportunity of closer examination of the children during the first year of life he will be better able to estimate the prognostic significance of any illness, and that the mothers' intelligent interest will make them readier to call for his advice. Further, the nurses will have gained the confidence of the mothers, who may often ask their advice regarding the need for the doctor's services; this is already occurring in St. Andrews. It is useless to ignore the fact that expense is frequently the cause of the mother's reluctance to send for a doctor; she desires to be assured of the necessity before spending money which she thinks might be better spent in procuring food and necessary comforts for her children.

Details Recorded on Children's Card.

Date, name, address, doctor.

(1) Glands, especially deep superior cervical—palpable or enlarged, (2) tonsils (normal, enlarged, unhealthy), (3) teeth, (4) nostrils (free or obstructed), (5) ears (earache or discharge), (6) diet, (7) failure of nutrition, including loss of muscle, (8) tendency to catarrhs, (9) exhaustion—disinclination for effort, (10) anæmia, (11) temperature—especially irregularities without obvious cause, (12) pulse—especially persistent rapidity and softening.

X ray examination of chest in all cases of glandular enlargement; blood examination in all cases of pallor; urine examination at Institute in all cases of failure of nutrition.

The condition of glands, tonsils and teeth is obviously very important. The enucleation of tonsils simply because they are enlarged is surely a most unscientific procedure. Enlarged tonsils often present a healthy appearance, yet from their size alone they may no doubt cause a certain amount of harmful obstruction. On the other hand, there may be purulent discharge from the crypts of tonsils of normal size. The deep superior cervical glands are selected for special note because of their close relationship to the tonsils and pharynx. We note carefully the condition of the nostrils in order to observe the onset of obstruction. No doubt complete nasal obstruction is commonly associated with the presence of adenoids, but what are the conditions which lead to this hypertrophy and degeneration of the lymphoid tissue of the naso-pharynx? It is reasonable to consider that the nasal obstruction due to recurrent attacks of coryza, with swelling of the nasal mucous membrane, may lead to defective aeration of the nasal passages, the accumulation of secretions, and decomposition due to microbic infection. Adenoids might possibly be prevented by simple attention to the condition of the nose from the earliest stages of life. When this obstruction occurs the Eustachian tube becomes involved, and it is the channel through which infection is conveyed from the naso-pharynx to the middle ear in cases of suppurative otitis media. Urbantschitsch drew attention long ago to the existence of Eustachian salpingitis in every case of chronic middle-ear suppuration. Further, tuberculosis of the middle ear is not uncommon in the infant, the tubercle bacilli no doubt finding their way along the Eustachian tube. Douglas Guthrie[13] states that in a children's clinic for ear and throat disease 90 per cent. of cases are tonsil-adenoid disease and middle-ear suppuration. The amount of suffering and ill-health which the prevention of such conditions would abolish demands attention to the earliest onset of symptoms with the hope that simple measures may then be effective. Lewin[14] points out that children are rarely taught to attend to their noses, and are allowed to acquire the habit of sniffing up discharges instead of blowing their nostrils free. Sprays and lotions are resorted to when the mischief has been done, and are troublesome and often ineffective. She suggests that very simple early measures might abolish the necessity for their use.

Tendency to catarrhs need not be dwelt upon, except to point out that they may lead to the formation of the suitable soil for the growth of the tubercle bacillus, if they are not indeed the indication of an underlying tuberculous infection. The whole relationship of respiratory catarrhs to tuberculosis has clear, and the reader is left in doubt at times as to which operation the authors actually advise for the different types of lesion. There is, however, a very full discussion of many disputed points such as, for instance, the value of occluding the pylorus or of the performance of gastro-enterostomy with a perforated gastric ulcer.

The book is one which no modern surgeon can afford to be without, for here is gathered in convenient compass an epitome of work collected from innumerable original sources.

DICTIONARY OF BRITISH SCIENTIFIC INSTRUMENTS.

Issued by the British Optical Instrument Manufacturers' Association. London: Constable and Co., Ltd. 1921. Pp. 335. 21*s.*

IT is not altogether easy to understand for what class of reader this work has been prepared. In substance it appears to be a catalogue issued by the Associated British Manufacturers of Optical Goods. Yet it is more than that. Certain chapters, devoted to the British optical industry, to navigating instruments, the Royal Meteorological Society, to British optical glass, and the Royal Observatory challenge a larger and more general interest than attaches to a mere trade catalogue, however extended and precise. But these more literary elements of the work are of very uneven quality. The chapter on the Royal Observatory is a compendious but very informing and interesting résumé of the work of that remarkable institution. The chapter on British optical glass again is well informed and readable. But the paper on the Royal Meteorological Society is drawn up like an annual report, and the short paper on navigating instruments is inadequate from every point of view. The most important part of the volume is the glossary —called a dictionary—of British scientific instruments; but a "dictionary" of scientific instruments of British manufacture which makes no mention whatever of the bistoury, scalpel, trephine, trocar, catheter, lithotrite, and dozens of other surgical instruments, seems to be misnamed. The fact that the publication is issued by a manufacturers' association would explain and even excuse the omission if the instruments specified were only optical. But seeing that the list does include specula, forceps, a cephalometer, and a milk jar, called by the curious name of "cremometer," it seems necessary to go farther than to the obvious principle of provenance to explain its limitations. Considered as a dictionary the work suffers from excessive compression. More useful and more intelligible than the too brief descriptions are the 150 pages of excellent engraved and photographed drawings of instruments manufactured or sold by the members of the Association. If the compilers of the book had shown literary faculty commensurate with the skill and taste with which the collection of diagrams has been prepared the work would have left us in no doubt as to its value from the readers' point of view.

JOURNALS.

Quarterly Journal of Medicine. Vol. XIV., No. 56, July, 1921.—Edgar F. Cyriax, in an article entitled Unilateral Alterations in Blood Pressure: the Differential Blood Pressure Sign, continues his observations upon the differences in blood pressure on the two sides of the body. This discrepancy, which he found to exist in a large number of cases of war injuries, he calls the "differential blood pressure sign." In the present series both medical and surgical cases were examined, and they were divided into two groups: (*a*) unilateral conditions, bilaterally unequal conditions, and operations performed upon structures in the middle line; (*b*) bilaterally equal conditions, and constitutional disorders. In the former group the differential blood-pressure sign was found in a large proportion of cases; in the latter group the sign was only present in about half as many cases. In all instances of spinal curvature investigated the sign was r [illegible] J. C. Spence describes a series of Ob[illegible] on Sugar Tolerance, with Special Reference to Variations Found at Different Ages. The blood-sugar curve is now generally recognised to be the most accurate method of determining sugar tolerance. He showed that the sugar tolerance is greater in infancy, but after the age of three a curve similar to those of young adults was obtained. Five apparently healthy men over the age of 60 were examined, and the sugar tolerance was found to be considerably diminished. In the four cases of cancer investigated, no definite change, apart from that attributable to age, was established.—J. W. McLeod, A. G. Ritchie, and C. A. Dottridge contribute an article on the Incidence of Infections with Pfeiffer's Bacillus Before, During, and After the 1918 Epidemic. According to the literature, Pfeiffer infections were rare in the early years of this century, but occurred in localised epidemics from 1915 onwards until the pandemic in 1918. Accepting the probability that Pfeiffer's bacillus is the causative organism of influenza, the authors have endeavoured to strengthen the view that there is a gradual diminution of infections with the bacillus in the years immediately following an epidemic, and a rise in the years preceding the next outbreak. They examined naso-pharyngeal swabs in 24 chronic venereal cases in the early summer of 1918, in 33 per cent. of which Pfeiffer's bacillus was isolated whereas in March, 1920, 47 similar cases were investigated and Pfeiffer's bacillus was found in only 8 per cent.—Thomas Lewis, in an article entitled "The Law of Cardiac Muscle, with Special Reference to Conduction in the Mammalian Heart," enunciates the Law of Cardiac Muscle as follows: "The fundamental properties of muscle will be found to vary in their degree in the four types of cardiac fibre; if for any two types we can obtain a measure, then within reasonable limits we may predict the degree for the remaining two types by placing all four in their natural order." The four types of cardiac fibre are (1) Purkinje substance; (2) auricle; (3) ventricle; and (4) a.-v. node. The Purkinje fibres are the largest, and contain most glycogen, the nodal fibres are the smallest, but on the other hand are the most rhythmic, and so probably the Purkinje fibres will prove to be the least rhythmic. The 2 : 1 response (half response) of cardiac muscle is described, in which the cardiac muscle only responds to every other stimulus providing they are supplied sufficiently frequently. The critical rate is greatest for auricle, less for nodal tissue, and intermediate for ventricle. The various conditions modifying conductivity are discussed, and emphasis is laid on the fact that the several properties of cardiac muscle have not been proved to be independent. In altered conductivity the cardiac function is probably depressed as a whole, but the four types of cardiac fibre are affected to different degrees according to the law of cardiac muscle.—Leonard Findlay, D. Noël Paton, and J. S. Sharpe: Studies in the Metabolism of Rickets. The authors commence their contribution by stating that the ætiology of the disease is no better understood now than when Glisson described it. Experiments were made to determine the calcium content of food, fæces, brain, and blood in rachitic and non-rachitic pups. The brain and muscles and the blood calcium content of the rachitic pups showed no divergence from the controls. The conclusion is therefore drawn that the calcium deficiency of the bones in rickets is not due to a deficient supply of calcium to the bones. The remainder of the paper is devoted to a study of the calcium balance in normal and in rachitic children. In normal children the excretion of calcium varies with age. During the first year of life, 35 per cent. of the calcium intake, which is high owing to the nature of the diet, is retained, and although the intake falls with the changes in diet as age advances, yet the utilisation percentage rises up to the time of puberty. The percentage utilisation in human milk is higher than in cow's milk, a fact that has not been explained. On comparing healthy with rachitic children no definite divergences were found. The utilisation of calcium in health and in rickets is fairly proportional to the intake, although in rickets slight discrepancies *no aphrodisiac symptoms or* œdema. The blood pressure remained constant (125 mm. systolic, 80 diastolic). The blood count on the 10th showed 6,150,000 red cells and 11,000 *leucocytes per* c.mm.; hæmoglobin 91 per cent.; there was no departure from normal in the differential count.

Treatment.—The patient took fluids very freely until *admission*; he was then limited to 2½ pints of fluid and no solids for 24 hours; he was given 4 oz. of lactose daily. On the 10th the fluids were increased to 3½ pints and he was *allowed plentiful carbohydrates.* Fats were added on the 13th and limited proteins on the 14th. He got up on the 24th and was discharged on the 28th.

Tests for renal function.—For four or five days after the patient's admission each specimen of urine passed was kept and tested separately. On admission the diastase content *of the urine* was low (5 units), but the patient was then drinking much fluid. Next day it was 20 units, and specimens tested during the next four days always contained between 10 *and* 20 units. *Only* one other specimen, on June 13th, gave a reading as low as 5 units. The blood-sugar was at first on the low limit of normal (0·085 g. per 100 c.cm. on *admission*), while the urinary sugar was 0·032 g. per 100 c.cm. But by 11th the blood-sugar had risen to 0·136 g. per 100 c.cm.; and the sugar in urine in g. per 100 c.cm. was *in different specimens* 0·080, 0·100 on the 9th; 0·120, 0·109, 0·106 on the 10th; 0·116, 0·122 on the 11th; 0·141 on the 12th; on the 13th it had fallen to 0·096 and 0·092. The sugar was *estimated by Dr. R. L.* Mackenzie Wallis, using his method for normal urinary sugar; the normal limits by this method are 0·06 to 0·08 g. per 100 c.cm. It must be *remembered that over this* period the patient was taking 4 oz. of lactose daily as well as other carbohydrates later, and the figures must be compared with the quantities of *urine passed.*

On admission the urea in his urine was 0·8 per cent. It was not thought justifiable to test his excretion of urea or *iodides during the acute stage. His blood-urea on admission* was 30 mg. per 100 c.cm.; 36·5 mg. per 100 c.cm. on the 11th—i.e., well within normal limits.

The patient was seen again on July 22nd, 1921, after a holiday. His urine contained no albumin, and no casts, red or white cells were seen in the centrifuged deposit. His *blood count showed* 6,600,000 *red and* 7400 *white cells* per c.mm. His blood pressure had, however, risen to 140 mm. (systolic) and 95 mm. (diastolic). A few weeks later *his blood pressure had fallen to* 112 *mm. (systolic).*

Discussion.

The case presents several interesting features, especially as regards the kidney lesion:—

1. The absence of vesication in the mouth and the relatively slight damage after a comparatively large dose of cantharidin suggests that not all of it can have been absorbed; cantharides, however, takes some time to blister. Much worse damage has followed the taking *of a relatively smaller amount of tincture of cantharides* in which the presence of chloroform as a solvent would perhaps assist the absorption of the cantharidin. Possibly in this case the butter taken with the patient's tea helped the *absorption of the drug.*

2. The rapidity with which the condition cleared up is worthy of note.

3. The signs and symptoms are those of a glomerular nephritis. Of *particular note in this connexion* are: (*a*) absence of œdema; (*b*) no great reduction in the fluid output; (*c*) hæmaturia with large numbers of leucocytes in the urine, moderate numbers of casts soon *disappearing*; (*d*) *normal* blood-urea; (*e*) normal diastase output; (*f*) a blood-sugar on the lower limits of normal (at first) with a urinary sugar on the upper limits of normal. It is as yet too early to lay much stress *on* this.

I am indebted to Dr. J. H. Drysdale for permission to publish the clinical details and to Dr. Mackenzie Wallis for permission to give the results of his investigations into the chemical pathology.

DISABLED SOLDIERS' AND SAILORS' WORKSHOPS CHARITY.—A subscription dance is to be held at Rectors on Wednesday, Nov. 16th, under the auspices of the *Disabled Soldiers' and* Sailors' Workshops Charity. The dancing salon has been given for the evening by the management, and the Duchess of Sutherland *has consented to act as* hostess. Price of tickets, if purchased before Nov. 16th, £2 each; if purchased on that day, £3 each. Tickets, and any further information *desired, can be obtained from* the Hon. Organiser, 177A, Kensington High-street, W. 8; remittances should be made payable to the Duchess of Sutherland.

Reviews and Notices of Books.

BIOCHEMISTRY.

A Study of the Origin, Reactions, and Equilibria of Living Matter. By BENJAMIN MOORE, M.A., D.Sc., F.R.S., Whitley Professor of Biochemistry, *University of Oxford.* London: Edward Arnold. 1921. Pp. 340. 21*s*.

Prof. Moore defines biochemistry as the study of the chemical substances produced by biotic energy, or the energy of life, in the bodies of living plants and *animals, and the* further study of the energy processes by which such substances are elaborated and used subsequently to their production for carrying on the life of the cell. The living cell and its energy exchanges are subject to physical and chemical laws, but the peculiar structure of living matter is inhabited by a type of energy not producible in the absence of life. The theme of the book is biotic energy. We have *before us all the author's views on this subject.* Though not accepted in their entirety by his colleagues, these views afford material for consideration and thought, as well as for further investigation.

Part of the book is a reprint of some of the author's papers in the Proceedings of the Royal Society and part is a re-edition of his contributions to Advances and Recent Advances in Physiology. The book is *not a text-book on the subject. The reader must* already be acquainted with the elements of physical and organic chemistry so as to follow the reasoning of the author. The papers reprinted from the Proceedings *of the Royal Society are those on the origin of life.* Life originates by the catalytic action of certain hydroxides, such as that of iron, upon the traces of carbon dioxide in the atmosphere. Light energy is converted into chemical *energy* by *the reduction* process to formaldehyde. Further chemical energy arises by the reduction of nitrates to nitrites in water by the action of light. Through the agency of the chemical energy so produced complex *organic* compounds are built up by unknown stages and ultimately the chloroplast as a special energy transformer. The small supply of nitrates, insufficient *for existing life*, can be supplemented by the conversion of atmospheric nitrogen by certain algæ. The living cell is peculiar in its special structure, consisting of a mixture of colloids and crystalloids in *common solution* in water. This mixture is endowed with an aggregate of physical properties and thus differs from a simple colloid like starch or albumin. Hence the cell has biotic energy. *Living matter acts as a transformer* between biotic energy and other forms of energy. All the energy is supplied by changes arising from chemical reactions in solution and they are initiated and controlled *by the substances in the* cell and in its secretions.

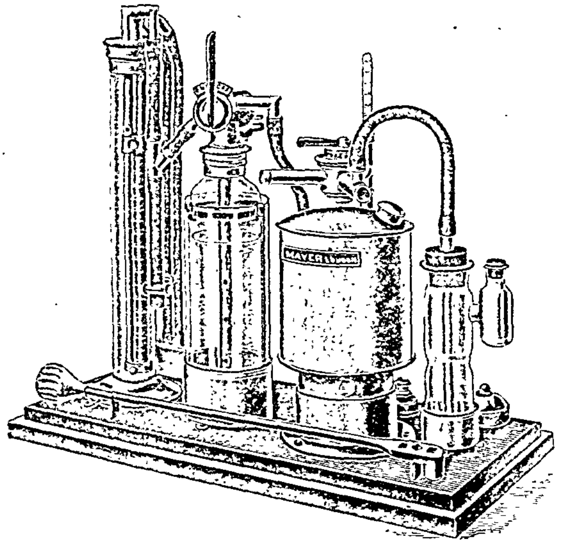
In Chapter XIV., on Secretion and Glandular Mechanisms, the most interesting section in *the book*, *Prof. Moore explains* the inner working of the cell. He argues thus: Since a really impermeable membrane does not exist and no animal cell has been proved to possess even a semi-permeable *membrane*, the *peculiarity of the* presence of excess of potassium in the cell and of excess of sodium in the plasma must be attributed to an active process of selective absorption against osmotic pressure. *The cell structure has a* definite affinity for the different ions; each ion passes in and out, but only in accordance with the affinity; the amount that passes through in either direction may be so small *that* it *is not* detected by chemical means. The work done in the secretion of urine can only be determined by reference to each constituent separately. In the case of urea, the *concentration in the urine is over* fifty times that in the blood, of sodium chloride scarcely double. By using a suitable formula the work done in their secretion is represented by 1211 calories per day. The *chapter concludes* with an excellent description of Pavlov's work on the connexion of the nervous system with secretion

New Inventions.

A COMBINED APPARATUS FOR INHALATION OR INSUFFLATION ANÆSTHESIA.

THE apparatus is designed for administering nitrous oxide-oxygen-ether by inhalation or insufflation, and ether by insufflation; it comprises the following units mounted on a wooden base :—

1. *Gas and oxygen sight feed.* consisting of two tubes, their upper parts of metal, and their lower six inches of glass, contained in a glass cylinder with a screw top. The outer ends of the tubes are fixed into the screw top and connected with the nitrous oxide and oxygen supply; the tubes inside are immersed in water up to their glass-metal junctions. They are pierced in their upper (metal) parts; the holes are of equal size, but the tube for registering nitrous oxide volumes has four openings, and that for oxygen only one. The gases issue from these openings and mix in the upper part of the glass cylinder, exerting, at the same time, a downward pressure on the water inside the glass tubes, and producing a water-level varying with the pressure of nitrous oxide or oxygen delivered, and therefore indicating the relative volumes of the gases passing through the feed. As there are four holes for nitrous oxide and one for oxygen, the volume of nitrous oxide passing into the apparatus is four times that of oxygen when the water-levels in the tubes coincide. A centimetre scale placed behind the tubes serves as an indicator, and enables one to recognise changes in the relative proportions of the gases passing to the patient. The mixed gases leave the sight-feed cylinder by an exit tube also fixed into the screw top. A water trap prevents a sudden rush of gas forcing water from the feed into the ether bottle.



2. *Ether bottle* provided with a two-way stopcock, by means of which the gases can either be passed straight to the heater or be deflected in any proportion through the ether. The tube dipping into the ether is pierced by six holes, bored on alternate sides at distances of half an inch. When the stopcock is first opened the gases pass out of the highest hole only and bubble through approximately half an inch of ether; on opening it wider they issue from two, three, or more holes, and each subsequent bubble passes through a greater depth of ether. In this way more or less ether vapour can be added to the gas mixture. The bottle is surrounded by water to prevent freezing, and has a mark half an inch above the highest hole, beyond which the ether level should not be carried. It is filled by a device resembling a reversed Junker bottle, which fits any ether manufacturer's bottle by means of a cork. One tube, which dips into the ether, is connected with a tap on the ether bottle of the apparatus, and the other, which just passes through the cork, carries a pair of hand bellows. On squeezing the bellows the air pressure is raised in the bottle and ether forced into the apparatus.

3. *Heater for warming the gases.*—The gases pass through a coil of wide-bore tube surrounded by a water jacket, which is kept hot by an ordinary electric bulb, preferably about 20 watt metallic filament. It is thus adaptable to any current or voltage, taking a lamp in ordinary use for lighting. A thermometer indicates the temperature of the gases as they leave the heater.

4. *Two-way tap.*—The gases leave the apparatus through a two-way tap, one limb of which carries a safety valve.

5. *Safety valve.*—Dr. Shipway has kindly given permission for his mercury safety valve to be fitted to the apparatus.

Methods of Use.

1. When used for insufflation of ether vapour only, the air supply is connected directly to the ether bottle and the strength of ether regulated by the stopcock.

2. When used with gas-oxygen-ether, cylinders containing the gases are laid horizontally on the lower shelf of the anæsthetic table and firmly secured to it by a long strap. (The carrying strap of the apparatus box serves for this purpose.) The flow of gases is controlled by one long key which fits both cylinders. The cylinders are connected with the gas feed by means of nozzles and rubber tubes. (*a*) For inhalation of gas-oxygen-ether, a bag and face-piece are attached to the plain limb of the two-way exit tap. The proportions of the gases are adjusted and more or less ether vapour added to them as the case demands. (*b*) For endotracheal or endopharyngeal insufflation, the tube going to the patient is attached to the limb of the two-way tap carrying the safety valve, and the gas mixture regulated as above. Induction may thus be carried out by gas-oxygen-ether via bag and face-piece attached to the plain limb of the tap. The catheter is passed, connected up with the other limb, which is protected by the safety valve, and the course of the gases is deviated by simply turning over the tap. For endotracheal insufflation an average of 120 gallons of nitrous oxide and 5 cubic feet of oxygen is required per hour; but for endopharyngeal insufflation a larger quantity is usually needed.

The apparatus has been used by me in over 500 cases at the Queen's Hospital, Sidcup, and elsewhere; the advantages claimed for it are: (1) Its portability; it weighs 15 lb. with cover. (2) Good control and steadiness are obtained by the long key and the method of fixing the cylinders; reducing valves or a cylinder stand do not seem to be necessary. (3) The fact that it combines three pieces of apparatus in one. (4) It renders easy the application of gas and oxygen to intratracheal work. Many of the cases which require an intratracheal anæsthetic are also those in which the non-toxicity of gas and oxygen is most desirable—e.g., excision of the tongue. (5) The method of filling the ether bottle obviates the danger of fire from ether vapour with an exposed flame, and prevents waste of ether. The heater appears to be a definite aid to an easy induction and a good anæsthesia. Apart from the necessity of supplying a warmed vapour in intratracheal cases, heating nitrous oxide seems to render it more potent, so that less ether is needed; and heating ether vapour renders it less irritating.

I have to express my thanks for the great amount of work in making, altering, and remaking many experimental models of each unit of the apparatus carried out in the first instance by Mr. F. C. Carr, a dental mechanic at the Queen's Hospital, and later by Messrs. Mayer and Phelps, New Cavendish-street, London, W., who produced the final model.

STANLEY ROWBOTHAM, M.R.C.S., L.R.C.P. Lond.,
Anæsthetist, Queen's Hospital for Facial and Jaw Injuries, Sidcup; Honorary Anæsthetist, Seamen's Hospital, Greenwich.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Sir William Taylor, past President of the College, was the guest at lunch of the Dublin Rotary Club on Sept. 12th. In the course of his address Sir William Taylor made some historical references to the Royal College of Surgeons in Ireland, the foundation-stone of which was laid in 1806. The two main objects of the College of Surgeons, he said, were, firstly, to improve medical and surgical education in Ireland, and, secondly, to provide a sufficient number of properly qualified surgeons for the British army and navy. The schools of anatomy and surgery which were established in connexion with the College made great progress and won wide celebrity. The College of Surgeons was a neutral establishment without regard to sect or politics. As an instance of its extensive work in this matter of education he said that one-fourth of those placed on the register in Ireland came from this College.

ANATOMY OF THE HUMAN ORBIT AND ACCESSORY ORGANS.

By S. Ernest Whitnall. Oxford Medical Publications. London: Henry Frowde, Hodder and Stoughton. 1921. Pp. 428. 35s.

Before his appointment to the chair of Anatomy at McGill University Dr. Whitnall had been a frequent contributor on orbital matters, large and small, to the Proceedings of the Anatomical Society, and he has now brought together these notes and fitted them into their appropriate places in a large work dealing with the anatomy of the region. In doing this he has enriched English medical literature, for this book is a veritable work of reference and a collection into English of the scattered results of investigators of all nationalities. The excellent bibliography at the end is an indication of the extent of his researches. The subject is not treated in any narrow sense, but includes the anatomy of the neighbouring parts, such as the accessory air-sinuses and the central connexions of the orbital nerves, abnormal muscles, and intracranial sinuses. We note in this connexion that Prof. Whitnall does not describe a vena centralis posterior. The illustrations, which are numerous, are mainly from photographs and are an excellent feature of the book; we would like to see some of these clarified or replaced by line diagrams, however, for it must be recognised that photographic illustration has its limits.

Altogether it is a book on which all the parties to its production are to be congratulated, and it will be in demand among students of ophthalmology.

MEDICAL GYMNASTICS AND MASSAGE.

Notes on Diseases Treated by Medical Gymnastics and Massage. By Dr. J. Arvedson, Arvedson's Gymnast Institute, Stockholm. Translated and edited by Mina L. Dobbie, M.D., B.Ch. London: J. and A. Churchill. Pp. 280. 8s. 6d.

When Dr. Dobbie produced her translation of Kleen's "Massage and Medical Gymnastics," it was the hope of those interested in medical gymnastics that she would continue her labours and translate this little book of Arvedson's, which has been a standard work throughout Scandinavia for the last 20 years. Certain inherent difficulties faced the author, for, in the first place, as the title indicates, the book is intended merely to present to the student notes on diseases, not to give a full description of them. In other words, the work is an epitome. Then, too, we are told in the preface that the book is intended to be read in conjunction with Kleen's handbook. The task of producing a satisfactory book on these lines is obviously great; but, when due allowance is made, there remain points for criticism. The book is designed for the use of students, and accuracy should therefore have been its keynote; yet errors abound.

Take Chapter VII., which deals with Diseases of the Nervous System. On the first page allusion is made to various movements with the object of bringing back arrested menstruation. Apoplexy is said to follow hæmorrhage from a vessel in the brain or its membranes, and we regret to note in the treatment of the result of hemiplegia that little distinction is drawn between true passive movement and forced movement. We are told that thrombosis in cerebral vessels is usually due to arterio-sclerosis; and the definition of ataxy as "inability to innervate the muscles accurately and sufficiently to perform a movement, so that it is performed uncertainly," is hardly satisfactory. The value of stretching the back in cases of tabes is not mentioned. It is definitely stated that there is no disturbance of the bladder in patients suffering from disseminated sclerosis, although precipitate micturition is recognised as one of the earliest symptoms.

On the ethical side, the author says that "orthopædic treatment is often necessary for these patients, and it is important that the gymnast should not waste time by opposing such treatment, but should instead explain the necessity of it, and insist upon it when it has been advised by the doctor." Such advice would hardly be required by gymnasts in this country.

In dealing with neurasthenia, little stress is laid on the fatigue element in its causation, and, although we read that these patients "must not be tired," the table advocated for the treatment of a neurasthenic patient seems to us far too severe. It is unusual to class such complaints as migraine and trigeminal neuralgia under the heading of rheumatism of the neck; and no mention is made of cervical rib as a possible cause of brachial neuritis, or of sacro-iliac strain as a cause of referred pain in back or legs. And there are astounding omissions, since adenoids and displaced cartilage in the knee are not mentioned, while it is entertaining to learn that roast beef and bacon are classed amongst foods "easily digested" by the chronic dyspeptic.

These are grave drawbacks for the learner. But the arrangement of the book is admirable, dealing as it does in turn with the morbid changes, the causes, symptoms, and treatment of each complaint in turn; and, were it revised so as to bring the medical aspect into accord with the teaching of the schools, its value would be great indeed. The style is clear and the translation excellent.

The Theory and Practice of Massage. Third edition. By Beatrice M. Goodall-Copestake, Teacher of Massage and Swedish Remedial Exercises to the Nursing Staff of the London Hospital. London: H. K. Lewis and Co., Ltd. Illustrated. Pp. 270. 12s. 6d.

For the most part this third edition is an exact reproduction of the second, but a short chapter on muscle re-education has been added which should prove a valuable addition to the work. Two new plates are inserted, of which the one showing types of enteroptosis as seen with the opaque meal explains to the student the nature of the condition far better than any words.

SURGERY OF THE UPPER ABDOMEN.

Second edition. By John B. Deaver, M.D., Sc.D., LL.D., F.A.C.S., Barton Professor of Surgery, Pennsylvania; and Astley P. C. Ashhurst, A.B., M.D., F.A.C.S., Associate in Surgery, Pennsylvania. Philadelphia: P. Blakiston's Son and Co.; London: H. K. Lewis and Co., Ltd. 1921. Pp. 832. £3 10s.

Inasmuch as no part of surgery has been more discussed of late than the lesions of the upper abdomen, an adequate text-book considering the whole subject will be welcomed. This volume is certainly the most complete treatise obtainable to-day. It is a second edition of a work formerly published in two volumes, but so great has been the progress since the issue of the first edition that the present one may be regarded almost as a new work. The wide experience of the authors in this branch of surgery is well known and their book is based almost entirely upon their own experience. At the same time alternative theories and views of treatment are thoroughly discussed, and although some surgeons may disagree with certain of the methods of treatment advocated, it must be admitted that a very strong case is made out in support of these methods.

The text is easy to read, is carefully arranged, and suitably illustrated. Symptomatology is perhaps not sufficiently discussed, especially with regard to the surgical diseases of the stomach and duodenum. Since diagnosis is admitted to depend to such a large extent upon the past history, more help should be offered as to the value to be placed upon different points in the history. In fact, the changes in the appetite, the different types of vomiting, and the character of the hæmatemesis are not discussed at all under the general diagnostic considerations, but only under the individual headings. Full attention is given to the more modern methods of diagnosis, and scattered throughout the book are some beautiful reproductions of X ray photographs.

The description of the operative technique is very lucid, but the account of the choice of operation is less agents are concerned in the ætiology of this mouse carcinoma: the first agent being the minute coccal bodies stimulating the cells to rapid division, and second, the cancer cell itself closely associated with the organism and transmitting from host to host in subsequent transplantations." It is well known that the transplantable carcinomata of mice and rats have characteristic individual features both morphologically and biologically, and retain their individuality through many years of transplantation. The one successful experiment of Dr. NUZUM out of 1200 mice proves too much. If the micrococcus cultivated from the Crocker Fund carcinoma No. 11 is capable of causing in a normal mouse the formation de novo not only of a carcinoma but of a carcinoma identical with the original carcinoma, we would have to conclude that each tumour strain has its specific parasite so that each spontaneous tumour must have its own specific parasite. The description of Dr. NUZUM's organism and the method used for its isolation reminds us of similar organisms which were isolated not many years ago and said to be the causative agents of a great many different diseases of a more undoubted infectious character than cancer, such as influenza, encephalitis lethargica, trench fever, and a number of others. They were found to be contaminations. The rapid growth of the tumour in mouse No. 250 and the high percentage of successes in the first transplantation are so different from the behaviour of a spontaneous tumour that a more obvious explanation suggests itself.

Information of a very different kind on the ætiology of cancer is furnished in a paper by F. D. BULLOCK and M. R. CURTIS read recently before the New York Pathological Society.[2] G. L. ROHDENBURG and BULLOCK had observed that, in rats, sarcoma of the liver is almost always associated with the *Cysticercus fasciolaris*—which is the larval stage of the *Tænia crassicollis* of the cat—and that the new growth arises in the walls of the cyst. In the recent communication BULLOCK and CURTIS record the results of an experiment in which a large number of rats were infected experimentally with the eggs of the tænia obtained from one cat. In October, 1919, 1165 young rats were thus experimentally infected by placing measured doses of an emulsion of the eggs in the pharynx. Of these rats, 600 animals all belonging to one strain, which proved to be particularly resistant to the infection, were subsequently eliminated. Of the remaining 565 animals 279 were alive on June 30th, 1920, when the first tumour was found. During the next six months 230 of these animals were killed or died from natural causes. Of these 55, or 29 per cent., had shown tumours by January, 1921. Forty-nine of the 279 are still under observation. The litters obtained from the original animals have been added to the experiment; there are about 2500 animals comprising four generations. Of the first generation 30 animals had by January, 1921, developed tumours. Since then until May tumours have developed in 125 additional rats, giving a total of 210 animals in which sarcomata have been produced experimentally. The tumours were morphologically sarcomata, composed of either spindle cells or polymorphous cells. They arose in the cyst wall and showed rapid growth with invasion of the surrounding tissue and extensive metastasis formation. They were transplantable through several generations and were then, of course, no longer associated with the cysticercus. The malignant nature of these tumours is therefore clearly established. The authors attribute the origin of these neoplasms to the chronic irritation of the cysticercus acting over a sufficiently long period on a susceptible cell—the connective tissue cell of the rat. This work, which was carried out in the laboratories of the Crocker Cancer Research Fund in New York, is of the same fundamental importance as the recent work of FIBIGER on spiroptera cancer and as the experimental production of cancer obtained by YAMAGIWA and ISHIKAWA in rabbits and by FIBIGER and by MURRAY and WOGLOM in mice subjected to painting with tar over a long period.

◆

A Clean Milk-supply.

IT is a comment on the national neglect of agriculture that legal enactments concerned with the sale of milk are in the hands of doctors, while agriculture has but a secondary place in the promotion of these enactments and no effective share at all in their execution. This position has arisen, at least in part, from the facts that this country was the first to devise active measures in promoting public health and that it was the medical profession which first took up the serious study of bacteriology and thus discovered that milk might be a source of disease. It was a misfortune that no such studies were made at that time on behalf of the milk industry, for combined effort by agriculture and medicine might have effected early and great improvements in the milk-supply. As it was, the attempts made were almost entirely of a legislative character, carried out by a body not directly concerned with agriculture whose criticisms of dairy methods were apt to raise a smile from the farmer. Even now there are serious agriculturists to assert that better methods of milk production and distribution are problems for public health and not for agriculture. The grave financial losses incurred as a result of bad methods of handling and distributing milk were not realised in the industry itself and the appeal from outside for an improved supply fell upon deaf ears. Even in dairy schools clean milk production was not taught. Such was the position which faced the Research Institute in Dairying when it was founded at University College, Reading, in 1913.

In the early days the outlook was not very hopeful. The gross annual income of the Institute was £1500; laboratories had to be created in an old house and workers found. The staff had no dairy farm or dairy under their control. Inquiry, however, soon showed that unclean methods of milk production and distribution were a source of grave loss to the industry. Work upon these subjects was, therefore, begun and has been continuously carried out at the Institute for the past five years. In the light of the results already gained it is clear that the problem of its milk-supply must be worked out by each country according to its own needs, since the conditions at the farms, the times of storage, and consequently of the age of the milk when distributed, and the temperature conditions to be encountered, vary greatly in different climates. Methods of management cannot be translated en bloc from one country to another. A further need for the continuance of these studies lies in the fact that the longer the work is carried on the clearer it becomes that the creation of an improved milk-supply lies with the worker. Each person who handles milk must acquire, along with his practical knowledge, the kind of technical skill that is found in an operating theatre. At present there are few such technicians available in the milk industry, but the study of the effects of variations in technique upon the ultimate state of the milk is constantly do occur, and in cases of some duration the retention may be above the normal for that age, probably indicating that recovery is taking place.—D. Murray Lyon writes on Blood Viscosity and Blood Pressure. The viscosity estimations were made with Determann's viscosimeter. The author shows that in healthy individuals the viscosity of the blood rises to a maximum during the third decade of life, and then gradually falls, the curve following very closely that of the red blood corpuscle count, but not corresponding with the blood-pressure curve. In disease there is no close parallelism between blood viscosity and blood pressure. Martinet divided cases into three groups: (1) "Les eusystoliques," in whom the blood pressure corresponds with the blood viscosity. (2) "Les hypersystoliques," where the blood pressure is high, but the viscosity is low. (3) "Les hyposystoliques," where the blood pressure is low but the viscosity is high. Murray Lyon found that in anæmias and in cyanosis there is the closest correspondence between the blood pressure and blood viscosity, but in other conditions, owing to the compensatory power that the body possesses, the blood pressure is not markedly influenced by the blood viscosity.

---

[2] [illegible] of the New York Pathological Society, N.S., [illegible] 3, October–December, 1920.

The Biochemical Journal. Vol. XV., No. 2, 1921. Cambridge University Press. 20*s.*—A Comparative Investigation of the Corresponding Proteins of Cow and Ox Serum, Cow's Colostrum and Cow's Milk by the Method of Protein Racemisation, by H. E. Woodman. Armed with this new method with which to attack the baffling problem of the chemical architecture of the protein molecule, Woodman finds that lactalbumin is identical with the albumin of colostrum, but that it is a substance distinct from serum-albumin. From this it is concluded that a distinct mammary synthesis is necessary for lactalbumin as well as for caseinogen. The euglobulin and pseudoglobulin fractions from serum and from colostrum are all shown to consist of the same individual protein, which is further identical with the serum-globulin. Incidentally, it is shown that the corresponding proteins of cow serum are identical with those of ox serum—the difference in sex of the animal not being accompanied by a difference in the constitution of its proteins—and that heat coagulation and variations in the mode of preparation are without effect on the rate of racemisation of globulin.—On the Theory of the Barcroft Differential Blood-gas Apparatus, by T. R. Parsons. It is shown by direct experiment that the constant of the Barcroft apparatus is the same when it is used to measure an absorption as when it is used to measure an evolution of gas. Mathematical calculation shows that a difference of constant would be expected in the two cases, but also that this difference is so small as to be well within the limit of the experimental error involved in the ordinary use of the apparatus. This result justifies the assumptions made during the determination of the percentage saturation of blood with oxygen by Barcroft's method.—On the Physiology of the Silkworm, by A. P. Jameson and W. R. G. Atkins. The contents of the gut of the silkworm are shown to be markedly alkaline, the pH value being as high as 9·0–9·4. The chief digestive enzyme in this animal is an amylase, which differs from most starch-splitting enzymes in that it can act in a strongly alkaline medium.—The Influence of Reaction on Colour Changes in Tryptophan Solutions, by E. C. V. Mattick and R. S. Williams. The growth of *B. proteus vulgaris* in tryptophan solutions acidified with hydrochloric acid or made alkaline with caustic soda was studied. In solutions whose pH values were below 8·05 no growth took place; over the range from this value to a pH of 9·41 growth occurred and was accompanied by the formation of orange or yellow-coloured bodies; in a still more alkaline solution growth also took place but no coloration was observed, until finally, at a pH of about 9·6, the organism was found to be incapable of surviving.—Methods of Measuring the Opacity of Liquids; The Relation between the Number and Size of Red Corpuscles and the Opacity of their Suspensions; The Relation between the Microscopic Appearance of Precipitated Calcium Oxalate and the Opacity of its Suspensions; The Opacity of Serum Diluted with Distilled Water, Physiologically Normal Saline, and Ringer's Solution, by J. Holker.—On the Composition of the Unsaponifiable Matter of the Ether Extract of Human Fæces, by J. A. Gardner. By dint of elaborate fractionation of the non-saponifiable matter of human fæces a new sterol has been isolated, of which the constitution has not yet been determined. It is certainly not oxycholesterol.—The Antiscorbutic and Antiberi-beri Properties of Certain Sun-dried Vegetables, by J. A. Shorten and C. B. Ray. The vegetables are steamed or scalded for a few minutes before the sun-drying. This process retains the antiscorbutic vitamin of the coarser vegetables such as potatoes, tomatoes and cabbage, but destroys that of the more delicate products such as carrots, brinjal, spinach, turnips, and turnip-tops. Factory-dried mixed vegetables are also found to be devoid of antiscorbutic properties. The sun-dried carrots, brinjal, spinach, cabbage, tomatoes and potatoes were found to prevent the appearance of neuritis in fowls on a polished rice diet.—On an Autoxidisable Constituent of the Cell, by F. G. Hopkins. In this paper Prof. Hopkins describes the isolation of the autoxidisable dipeptide of glutamic acid and cystein, "glutathione," which is responsible for the nitroprusside reaction in tissues.—The Influence of the Nervous System on the Excretion of Creatinine; Experiments on Nervous and Mental Patients, by A. A. Weinberg. It is found that the excretion of creatinine in nervous and mental patients is not entirely determined by the degree of muscle tonus, as a high excretion is observed in patients in whom the tonus is diminished. The amount of creatinine excretion seems to depend on the functional connexion between the cerebrum and the muscles, and becomes excessive when this connexion is interrupted.—The Salt Effect in Alcoholic Fermentation, by A. Harden and F. R. Henley. Salts in general are found to depress the rate of attainment of the maximum rate of fermentation of glucose and fructose by zymins. This is due not to an inhibition of the carboxylase enzyme which attacks pyruvic acid, but to a diminution of the rate of action of the hexose phosphatase.—Observations on Abnormal Iodine Values, with special reference to the Sterols and Resins, by I. Smedley MacLean and E. M. Thomas. This is a study of the iodine numbers of a wide range of substances as determined by the use of Wijs's reagent (iodine monochloride in glacial acetic acid) and Hübl's solution (mercuric chloride and iodine in 95 per cent. spirit).—The Effect of Exposure to Low Temperatures on Some Physiological, Chemical and Physical Properties of Amphibian Muscle, by D. L. Foster and D. M. Moyle. The irritability to induction shocks of frogs' muscles stored in air or oxygen at 0° C. falls off at first rapidly, then more slowly, and finally, after the lapse of about a week, more rapidly again. On the other hand, in nitrogen a rapid fall of irritability was maintained throughout. This loss of irritability in the case of muscles kept in air or oxygen was not due to accumulation of lactic acid; it was not accompanied by rigor. But the muscle rendered non-irritable by storage at 0° C. was found to be capable of producing lactic acid (just as is a fresh muscle) when kept at room temperature, exposed to nitrogen or toluene vapour, sent into heat rigor or submitted to mechanical injury. The non-irritability of the muscle is not due to lack of power of producing lactic acid, but to some physiological changes occurring on long exposure to the ice-cold temperature. Experiments on the increase of weight of these muscles in various solutions show that a solution which would be isotonic with a normal muscle is hypertonic to the non-irritable; the physical change which has occurred is therefore either a change in permeability of the muscle membranes or a diminution in the number of osmotically active particles in the muscle substance. There seems to be some degree of recovery of the irritability after perfusion of saline solutions.

In the discussion which followed the reading of Dr. Savage's paper, General Sir Layton Blenkinsop expressed the opinion that many of these cases would not arise if animals destined for human food had to be slaughtered under efficient medical supervision, and that a person who supplied the public with food of any sort became a public servant, who should conform to Government regulations, and should have no claim in that connexion to be considered a private individual. Prof. F. Hobday contrasted the state of affairs in this country, where, in his view, the value of collaboration had not been realised, with that obtaining on the Continent, where medical men and veterinary surgeons collaborate in the laboratory and in the field. He also contended that the absence of State aid, and pecuniary aid generally, had severely hampered younger members of the veterinary profession; and that the reason why there was not more disease in England was the general custom of cooking food well before eating it. Mr. W. M. Scott, President of the Association, disagreed with Dr. Savage's view that food for human consumption was more likely to be contaminated after death than during life, maintaining that many animals apparently in excellent health can really harbour organisms of various kinds. Sir Clifford Allbutt, who was unable to be present, referred, in a letter which was read to the meeting, to the successful meeting held at the Royal Society of Medicine in February, between that Society and the Central Branch of the National Veterinary Association,[1] and pointed out that fusion of medical and veterinary practice was impossible; veterinary surgery must retain its own examinations and qualifications. In Cambridge what they were aiming at was to found a school of research in animal and plant pathology, and to present preliminary sciences to the student in a way that would serve both professions.

BRITISH DENTISTS' HOSPITAL.

THE ninth annual report of the British Dentists' Hospital, which has just been issued, contains statistics showing a rapid growth of the work carried on at the various centres and clinics of the Dentists' Hospital service. The rules of the hospital provide that fees are to be paid by patients; a scale is fixed on this basis, but the Executive Council reserve the right to vary this scale in exceptional cases. Payment by instalment is permitted; dentures must be paid for when supplied unless payment is guaranteed by some responsible person or society. All treatment is carried out by dentists holding the L.D.S. diploma, who are also members of the British Dental Association; anæsthetics are administered by medical men. Thus a standard of skilled dental care similar to that of private practice is secured and maintained. Each treatment centre is under the charge of a resident matron. The intended establishment of centres throughout London was rendered impracticable by the war, and the report speaks of general apathy on the part of the majority of dentists in the matter of a qualified dental service for the masses. The provision of dental clinics for maternity and tuberculosis patients has rapidly extended during the year. At the Camden Town, Lewisham, and Clapham Common centres the hospital has working agreements with the St. Pancras, Lewisham, and Wandsworth Borough Councils respectively, enabling mothers attending local welfare centres to obtain dental treatment and the provision of artificial teeth. The Battersea, Fulham, Hampstead, Holborn, and Southwark Councils have also arranged with the British Dentists' Hospital for the institution of dental clinics for the same class of patients at the council centres; the equipment and the services of dentists are provided by the hospital executive. At Greenwich, Hampstead, Holborn, Paddington, and Wandsworth, under agreements with the hospital, patients attending the local tuberculosis dispensaries obtain advice and necessary treatment on the recommendation of the medical officer of health. Most of these clinics have been opened during the year. The earlier experiments at Greenwich and elsewhere were carefully watched by medical officers of health of other London boroughs, and by the authorities at the Ministry of Health, and sanctions for the establishment of similar clinics resulted from a conviction of the real value of the work made possible by them. By a recent agreement the number of L.C.C. school children to be attended to annually at the treatment centre at Rushey Green has been increased to 2200. The executive has also agreed to provide dental treatment and advice for the 500 male members of the Oxford and Bermondsey Insurance Society at a clinic to be established in the neighbourhood of Tower Bridge-road and Grange-road, Bermondsey. Dental propaganda work has not been overlooked; literature has been regularly distributed to the patients, and a number of lectures have been given during the year. The year's record is of an organisation that deserves encouragement and support.

CHOLERA PROPHYLAXIS.

AN efficient cholera quarantine depends naturally upon a sufficient and pure water-supply, but more especially under modern conditions upon rapid and efficient laboratory methods of detecting carriers of the cholera vibrio. It is well known that these carriers may be in apparent rude health, but as in the case of enteric and other intestinal disorders of bacterial origin they may, and probably are, under favourable circumstances the starting-point of an epidemic. An organisation capable of examining thousands of pilgrims for the cholera vibrio has to be based upon the most efficient methods for isolation of this organism. Special selective media, such as the alkaline agar of Crendiropoulo, have been generally adopted, but the plating out of each individual stool and the search for the cholera vibrio on the incubated plates is a lengthy and tedious procedure. The recognition of the cholera vibrio has been greatly facilitated by the employment of specific anticholera sera of high titre, which are capable of clumping the organism in such manner as to be visible to the naked eye, even in high dilutions. Such a method was introduced by Otto,[1] who by enrichment media and plating out on Dieudonné's medium, and employing the agglutination test for the recognition of the colonies, was able to make a positive diagnosis in 48 hours. By employing numerous labour-saving devices he estimated that in order to examine 10,000 stools daily it is necessary to employ a staff of 35 persons (of whom three should be specially trained doctors with bacteriological experience, and six trained laboratory assistants). It has been found by Bandi,[2] that with the addition of a minute amount of cholera-immune serum to the primary culture tubes of peptone water, a most distinct visible agglutination of the vibrio takes place, so that the tedium of the process of recognition can be still further reduced.

An improvement upon this method, utilised by Arthur Davies in an epidemic in Palestine, was described by him in the *Journal of the Royal Army Medical Corps* for October, 1920. By mixing the suspected peptone water culture with cholera serum on a glass slab—known as Garrow's agglutinometer—on which macroscopic agglutination rapidly takes place, it was found that the presence of vibrios in the primary culture could be more accurately detected than by any visual method. A provisional report upon a suspected stool could thus be submitted within 18 hours of the receipt of the specimen. Moreover, the procedure, as worked out, was found to be so simple that a trained worker was capable of examining no less than 200 suspected stools during a day's work of eight hours.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 24, 1921.

Health Insurance and the State.

WHATEVER may lie behind a rumour that the continuance of the Insurance Act is being reconsidered in high quarters, at all events the position is sufficiently serious for all parties concerned to review the situation and to think over calmly the advantages of a scheme of compulsory health insurance on a large scale and whether they do or do not counterbalance the drawbacks. During the last ten years many and varied cries of disapproval have arisen from friendly societies, from the medical profession, from the contributing employer, and from the contributing employed person; although the last-named, the corpus vile of the Act, has less ready means to hand of rendering himself vocal. No one who has closely studied the working of the Act from anywhere within its orbit during this decade will dispute the justice of some of these complaints. Dr. H. G. COWIE sets them out vividly in our correspondence columns for the London area. Obviously it would have been impossible to carry through the greatest constructive health measure of our generation without coming up against conflicting interests. It was, for instance, hardly to be expected that the smaller and struggling friendly societies would like to be snuffed out because they had not in 1911 established themselves on a satisfactory financial basis. With the experience of the club system before the eyes of medical men in industrial areas it was natural for a State insurance medical practice to seem nothing other than a larger and no less objectionable club practice in which the doctors were obliged, by economic pressure, to give services satisfactory neither to themselves nor to their patients.

The Act has not yet had anything like a fair ten years' run. Up to 1914 it was largely a question of determining by the familiar plan of trial and error the details of working, and when the beginnings of a satisfactory working basis had evolved the war came and paralysed further development. In spite of this the Act has worked so well for the friendly societies that they now have at disposal a surplus large enough to be coveted for a number of useful purposes, and the *National Insurance Gazette*, which is devoted chiefly to the interests of the National Insurance Act, admits that the Treasury contribution of two-ninths to supplement the contribution of employer and employed might be withdrawn without seriously imperilling the working of the insurance principle. In the medical profession opposition has dwindled to small proportions, not merely, as has been hinted, because medical benefit is good business for the doctor, but because, in a large and true sense, it is solving the problem of medical practice in densely populated areas The practitioner no longer accepts, with what good grace he can, a modicum of poorer patients, making up his loss from the remainder of a large mixed practice; insurance practice in an industrial area is now such as to attract young men and women with high academic qualification and untamed ambition. This alone is sufficient to justify the practical working-out of the insurance principle.

For it must not be assumed that, if the State renounced its quota towards health insurance, the contributory principle would fall to the ground. Everything points to the friendly societies being prepared to continue to offer medical benefit, making their own terms direct with the medical profession. We have no reason to doubt the possibility of cordial relations between these two administering agents in an insurance scheme. On neutral Government ground they are learning with great advantage to work together, as may be seen in several large centres in which the chairman of the panel committee is also the chairman of the insurance committee. On the other hand, there is nothing unlikely in a large industrial undertaking organising its own medical service to the entire satisfaction of both parties. This may, indeed, come about naturally in the course of time as a further development of welfare work, for when some such suggestion arose in the mining industry of South Wales the health benefits were construed in a generous sense, to include dentistry, nursing, and hospital provision. For the moment the advantage of the insured person himself is surely best secured by the continuance of the Act. The benefit to which he is entitled has grown considerably during the ten years, and has only been set back by the war and its aftermath in the same way as the quality of food-supply and other necessaries. Those, therefore, if such there be, who would demand the withdrawal of the Government as the third party in a great health contract between employer and employed should consider whether the time has yet safely come when health insurance can be left to the clash of conflicting interests. The State itself has a big responsibility in the matter.

The Cancer Parasite: Facts and Fancies.

IT is necessary nowadays to keep a sharp watch on the cancer parasite. In a paper[1] entitled "A Critical Study of an Organism Associated with a Transplantable Carcinoma of the White Mouse," Dr. J. W. NUZUM, of Chicago, claims to have isolated from a mouse carcinoma (the Crocker Fund carcinoma No. 11) under partial anaerobic conditions a minute filtrable Gram-positive non-motile micrococcus. The method was that employed by NOGUCHI for the cultivation of filtrable viruses. Pure cultures of the micro-organism are said to present uniform morphological and cultural characteristics, but on the same page on which this statement appears it is also said that "an intensive study of the morphology of this organism has shown that the micrococcus is extremely pleomorphic." Sometimes larger forms appear in cultures approximating the staphylococcus in size. Injections of pure cultures of the organism into the breast tissues of mice have frequently produced nodules which grow progressively for 10-30 days and then slowly regress in the majority of cases. Microscopically these nodules show "a mass of newly formed tissue cells rapidly dividing and supported by a newly formed stroma which becomes vascularised." In one mouse (No. 230) the injection of a pure culture produced within a week a rapidly growing tumour. The tumour was palpable after one week and after four weeks had reached the size of a walnut. On microscopic examination it showed "a typical alveolar carcinoma identical histologically with the original carcinoma." On transplantation it grew rapidly and gave 60 per cent. of successful inoculations.

The author is careful not to claim that he has discovered the cause of cancer. He thinks that "two were actually fewer cases of tuberculosis among the women addicted to drink, advanced cases were somewhat more frequent among heavy drinkers. For further information on the subject of tuberculosis and prostitution, which possesses clinical, epidemiological and social interest, Dr. Samson refers the reader to his recently published monograph.[2]

SMOKE.

THEORIES about the causation of fog, arguments based on the reduction of the washing bill, diatribes as to the folly of allowing unburned fuel to go up the chimney, records showing the loss of sunlight in industrial towns, the damage done to the masonry of buildings, private and public—all these have hitherto failed to produce a public opinion sufficient to energise a really active campaign against the smoke nuisance. It is just possible that the practical recent demonstration of how much the joy of life in a town is increased by a clear atmosphere may succeed where these other arguments have failed. The beauty of London during the recent spring and summer months will not be readily forgotten. The discussion on smoke abatement at the Edinburgh meeting appears to have taken a practical turn. As a rule speakers are inclined to argue that domestic fires being the chief cause of the trouble it is hardly worth while bothering about factory chimneys. But at Edinburgh members of the British Association pointed out that although two-thirds of the London smoke may be due to domestic chimneys, the case is different in many manufacturing towns. Smoke from factory chimneys can be dealt with, even though we have no legal power to deal with domestic fire smoke, and the nuisance could be largely abolished except in the case of a few metallurgical furnaces. The difficulties in the way of bringing effective pressure to bear are notorious, but not insurmountable; the will, however, to act on our present powers seems strangely lacking. One has only to read regularly the annual reports of medical officers of health in order to appreciate the fact that the prevention of smoke is a veritable Cinderella among the interests of health committees. Local authorities whose duty it is to carry out the law are seemingly obsessed by a superstitious reverence for a smoky chimney as the necessary concomitant of good trade. Owners of smoky chimneys are generally fairly well represented on the local authorities. Moreover, the chimneys of the local authority, such as those of the public baths, isolation hospital, or electric power-station, are sometimes the worst offenders.

A SCHOOL OF RADIOGRAPHY.

THE first school of radiography to be established in the United Kingdom is to be opened at King's College Hospital, London, next month under the direction of Dr. R. Knox, hon. radiologist to the hospital. It is intended for the training of technical assistants in X ray and electrical departments, and the classes will be under the supervision of Dr. Knox and the assistant radiologist, Dr. H. A. Colwell, while the teachers also include Mr. C. P. G. Wakeley, F.R.C.S., and Mr. A. O. Forder, M.S.R. The course of instruction comprises general elementary physics: sound, heat, and light, ideas of measurement, energy, mass, and so forth to be incorporated as the subject progresses. Electricity, from a knowledge of electrical terms, electrical attraction and repulsion, cells and batteries, the theory of ionisation, sinusoidal currents, condenser discharge apparatus, static machines, functions of electrical measuring instruments, leading on to the construction of apparatus, and how to manage Coolidge tubes and controls, accumulators and transformers, with practical deductions for localisation of foreign bodies, methods of dosage, application of diathermy, high frequency, ultra-violet rays, and radium. Anatomy, as far as the development and elementary morphology of human skeleton, surface markings and positions of the chief viscera. Photography, covering photographic chemistry, lantern slide making, printing, enlarging, copying, and clinical photography. The school is open to both men and women over 18 years of age, the course of instruction lasting a year and being preparatory to the examination of the Radiographers' Society. This examination has been established with a view to securing adequate training upon scientific lines for skilled non-medical workers in X ray and similar departments. The enormous developments of radiology—both from a therapeutic and from a diagnostic point of view—have made a thorough grounding, in theory as well as in practice, essential; and it is realised that a few months spent in an X ray department with little or no systematic training are quite insufficient to produce an efficient and skilled worker. The possession of the diploma of "Member of the Society of Radiographers" (M.S.R.) will therefore be evidence, not only that the holder has passed an examination, but that he or she has had systematic practical and theoretical training in the subject for at least a year. The number of students in each course is limited, the fee for the full course being 35 guineas. Inquiries should be addressed to the Radiographer, King's College Hospital, Denmark Hill, London, S.E. 5.

INDIRECT DETERMINATION OF FUNCTION.

EXPERIMENTAL physiology is liable to the reproach that deductions may be made from results obtained under unnatural conditions, and that laboratory findings are not always upheld by practical experience. An example of this is afforded by the antidiuretic effect of pituitary extract in man, despite the highly diuretic properties originally attributed to it as the result of physiological experiment. It is well recognised that psychical and irrelevant factors play an important part in modifying the functions of bodily organs. The pulse-rate is frequently increased as the result of the excitement induced by a medical examination, and the blood pressure may be raised by the novelty of the processes used in estimating it. Any indirect method of observation which eliminates this psychical factor is likely to give a more accurate picture than if the patient is aware that direct observations are being made. An example of this is afforded by the electrocardiograph, by the use of which a graphic representation of the heart's action can be obtained while the patient lies quietly in bed, and no attention is paid to the heart.

In a recent issue we published an article by Dr. E. C. Dodds in which this method of investigation is carried a stage further. The reaction of the secretions of the stomach and duodenum is determined by means of a series of examinations upon the alveolar air. The psychical factor can thereby be eliminated, as the patient is completely unaware that his gastro-intestinal functions are the subject of research. Direct methods of determining the reaction of the gastric secretions are liable to errors, as the result of the emotional influence of the experiment, the unappetising nature of the test meal, and the possible mechanical effect of the swallowed tube upon the gastric glands. Drs. T. Izod Bennett and J. F. Venables using the fractional method of gastric analysis have demonstrated the emotional inhibition on gastric secretion, by making suggestions of nausea and anxiety to normal subjects under hypnosis, and although, as Pavlov originally showed, mechanical stimulation alone of the gastric mucous membrane will not cause secretion, yet the passage of the stomach tube through the œsophagus in some cases leads to a copious flow of saliva, which necessarily lowers the acidity of the stomach contents. Dr. Dodds, when testing a Haldane gas analysis being carried forward at the Institute. By means of demonstrations, classes, and lectures, and the circulation of its publications, the results of that study are spread abroad, and every year a greater number of persons within the industry is acquiring the requisite skill.

---

[2] Prostitution und Tuberkulose, Klinische und Social-Medi- Untersuchungen. Leipzig: Georg Thieme.

This is no small work for a single Institute to have accomplished within eight years. The fact that its work is now being appreciated at its proper value by the milk industry is shown by the long list of inquiries received every year, by the increasing number of clean milk competitions promoted by county councils or by dairymen, and by the applications for help in preparing clean milk demonstrations at agricultural shows. Throughout its career the dairy teachers have given the Institute their cordial support and have incorporated much of its work in their daily teaching. They have remodelled the syllabus of dairy education in order that methods of clean production may form part of the student's course. The Ministry of Health has given financial support to the work of the Institute, admitting in so doing that the problem of clean milk is one to be solved by combination of effort between agriculture and public health. At Birmingham, at Salford, and we hope shortly at other towns, the medical officer of health, those engaged in the milk industry, and the agricultural education establishment in the district are working together to improve the supply of milk. When those who administer the milk regulations take a sympathetic interest in the difficulties of the milk industry, a long step will have been taken towards a solution of hygienic dairying.

◆

TUBERCLE AND RESTRICTED MIGRATION.

THE conditions[1] under which emigrants from the United Kingdom who have suffered from tuberculosis will be admitted into the Commonwealth of Australia are less interesting than the conditions under which they will be deported thence, at their own expense, should they have the ill-fortune to suffer relapse. The Commonwealth Government are willing, subject to certain conditions, to admit persons in whom the disease has been arrested, if they have received the education of a period in a sanatorium and have, in addition, been symptom-free for at least 12 months. The conditions of admission include certification by a medical man who is an expert in tuberculosis, preferably by a tuberculosis officer, for whose services the Commonwealth Government is willing to pay a fee of one guinea to the local authority. A satisfactory report having been furnished, the intending emigrant must then obtain the formal consent of the Commonwealth Minister for Home and Territories before admission. It is only to be expected that such persons shall be subject to the ordinary examination by the quarantine medical officer at the port of disembarkation, and it is not unreasonable that in the event of their disease having become active during the voyage they should not be allowed to land. But it is the last provision in the circular asking for the coöperation of local authorities in this scheme which may well dishearten those unfortunates with a past history of infection and present prospects in Australia. "They will be liable to report themselves for examination at the end of each 12 months during the first three years spent in Australia, and in the event of the disease having become active during that period they would be liable to deportation at their own expense." The acceptance of a citizen, after due precautions, might, we think, entail recognition of responsibility for a risk which has been taken with open eyes by a new country hungry for immigrants.

Annotations.

"Ne quid nimis."

CHILDREN'S ORTHOPÆDIC CENTRES.

DURING the past few years it has been necessary to organise physical treatment by massage, exercises, and electrical methods on a very large scale for the treatment of disabled soldiers. The first institution which became prominent in carrying out this sort of treatment was the Grand Palais Hospital in Paris. Visitors from this country to Paris criticised the work of this institution in that the physical treatment was too much divorced from surgical treatment; for example, stiffness following fractures and contractures from wounds were to be seen under treatment lasting over very considerable periods, whereas with better primary treatment they should never have been allowed to arise. In other cases, massage and electrical treatment were carried on for conditions which required preliminary surgical treatment or the use of splints or apparatus. In this country, although a good deal of physical treatment was carried out in convalescent or command depôts, the most important organisation in this line consisted in the formation of the many military orthopædic hospitals, in which physical treatment of all sorts was closely coördinated with surgical treatment. More recently a number of additional centres for the physical treatment or out-patient pensioners have been organised all over the country, some by the Ministry of Pensions itself, many by other organisations, particularly by the British Red Cross Society. The principle of coördination was kept by associating these centres, as far as possible, with the orthopædic hospitals, and by arranging that they were visited regularly by surgeons from these hospitals. Now at last the work of these centres in the treatment of pensioners is beginning to diminish, and some of them are turning their attention to the treatment of civilian cripples, particularly to crippled children. Here the problem is a very different one. Crippled children, in many cases, have suffered from tuberculous disease, in which the use of physical treatment, except under strict surgical supervision, is actually dangerous. A large proportion are suffering from infantile paralysis and spastic palsies, for the treatment of which massage and electrical methods, although often of use, are apt to be wasted unless closely coördinated with other varieties of orthopædic treatment. Centres for dealing with crippled children and adults should be of great service, particularly in districts which are not well served by hospitals, but, if they are to carry out their work to the best advantage, they must be brought within a complete scheme of orthopædic treatment and not exist as isolated bodies. The Central Committee for the Care of Cripples have had this matter under consideration and have drawn up an outline of principles (see p. 669) which should guide the establishment of orthopædic centres for children.

COMPARATIVE MEDICINE.

THE wide field common to workers in medical and veterinary science, and the necessity of a closer coöperation between them, were the main subjects of discussion at the recent quarterly meeting of the Mid-West and South Wales Veterinary Medical Association at Bridgwater. The feeling has long been growing on both sides that work in almost watertight compartments is a source of weakness; in a paper on "Bacterial Food Poisons" Dr. W. G. Savage referred to numerous conditions which are still obscure "because they touched on the work of the two professions and were neglected by both."

EXPERIMENTAL RICKETS.

THE causation of rickets, either experimental in animals or that form so frequently manifested in the human child, is far from settled. The study of experimental rickets continues to attract many observers in the United States, and in the Proceedings of the Society for Experimental Biology and Medicine (Vol. XVIII., 1921) there are a number of communications of considerable interest. A. F. Hess, G. F. McCann, and A. M. Pappenheimer describe experiments on rats to show that the view held by other observers that the development or non-development of rickets is dependent mainly on the absence or presence of the fat-soluble vitamin A or a vitamin closely associated with it—a vitamin sometimes called anti-rachitic—does not hold true either for experimental or human rickets. In young rats fed from three to four months or longer on a special diet markedly deficient in this vitamin there was no instance where rachitic lesions, either microscopic or macroscopic, were noted. That the dietary contained only a minimum of the fat-soluble vitamin was proved by the lack of gain in weight after the animals had been fed on the food mixture for about 60 days, by their prompt response in growth on the addition of 6 per cent. of butter fat to the diet, and by the development of ophthalmia or keratomalacia in almost all of the animals and its rapid subsidence on adding butter to the dietary. In addition to eye lesions the rats on a restricted diet developed many infections. Those receiving 0·5 c.cm. of orange juice did not, however, develop either ophthalmia or infections as frequently as others in which the diet did not include this food. Control animals which received the same diet with, however, an addition of butter did not develop ophthalmia, grew normally, and remained in perfect health. It was concluded that a lack of the fat-soluble vitamin in a dietary which is otherwise complete does not lead to the development of rachitic lesions in rats.

The same observers, with the addition of T. F. Zucker, experimented on the effects of various modifications of a diet known to produce rickets in rats; such a diet is one composed of patent flour, calcium lactate, sodium chloride, and ferric chloride. If, however, 0·4 per cent. basic potassium phosphate was substituted for an equal percentage of calcium lactate in this diet, the animals were uniformly protected against the development of rickets. The question arises as to whether it is to the potassium or the phosphate that the protective action of the basic potassium phosphate is due. By substituting sodium phosphate in one series of experiments, and potassium chloride in another, it was shown that the protection is conferred by the phosphate and not by the potassium. E. V. McCollum and some of his pupils in their studies on experimental rickets describe observations which demonstrate in a striking way the differences in the effectiveness of cod-liver oil as contrasted with butter fat in influencing the rate and extent of growth and their effects on the histological structure of bone. A restricted diet containing 3 per cent. of cod-liver oil, but deficient in calcium, induced fairly good growth and fertility during at least eight to ten months. The same food mixture with butter fat to the extent of 3, 10, or 20 per cent. of the food mixture fails to induce an appreciable amount of growth. The rats usually die within a few months. The same diet with 10 per cent. of casein added, but without the addition of either fat or cod-liver oil, causes pathological changes characteristic of rickets. With small amounts of cod-liver oil (3 per cent.) no rachitic changes are seen in the bones. Even 20 per cent. of butter fat fails to effectively direct the growth processes in the bones toward the normal condition. This food mixture, containing 3 per cent. of butter fat and 1·5 per cent. of calcium carbonate, is a highly satisfactory diet for the promotion of growth to the full adult size, the maintenance of high fertility throughout the breeding period of the females, and the successful lactation by the mothers. Without the calcium addition, but with 3 per cent. of butter fat, very little growth can take place. The striking differences between the nutritive properties of cod-liver oil, as contrasted with butter fat, only occur with diets in which the phosphorus content is approximately the optimum, and with the calcium content distinctly below the optimum.

The same observers experimented with a diet faulty in only two respects, and, when fed to the young rat, in a comparatively short time (three to five weeks) produced rickets. The diet was extremely poor in fat-soluble A, the anti-xerophthalmic substance, and young rats developed this condition in four to five weeks. The gross tokens of rickets in the rats were very marked and the microscopic evidence of rickets in the skeleton was convincing; the condition in the bone produced by the faulty diet was at all points identical with that seen in advanced rachitis of human beings. When butter fat (0·5 per cent.) was added to the faulty diet, xerophthalmia was postponed, but the pathological condition of the skeleton remained essentially unmodified; a 10 per cent. addition of butter fat effectually prevented xerophthalmia, life was prolonged, but rickets remained. If 2 per cent. of cod-liver oil was added no pathological condition of any sort—not even rachitic—developed in the skeleton. The authors conclude that butter fat is feeble in its anti-rachitic properties, and this fact seems to be of great practical importance in so far as the explanation of the occurrence of rickets in the human being is concerned. Cod-liver oil, on the contrary, is powerful in its anti-rachitic properties.

A SAFE WATER-SUPPLY.

THE rain which has fallen in the South of England during the past fortnight has been welcome enough to gardeners and allotment holders but has done little to replenish the starved water-supplies. Such a gush of water as there was in London on the night of Sept. 11th brings its own perils, for, as our Special Correspondent recently pointed out (THE LANCET, August 13th, p. 353), when the fear of scarcity has disappeared, questions of purity will immediately arise. What kind of water is going to be impounded, in unprecedented amount, into heavily depleted reservoirs, and will all wells yield, in due course, exactly the same quality of water as in the past? Six weeks ago it did not appear that the health of the community had suffered as a result of prolonged drought, but, in the week ending Sept. 3rd, 191 deaths from diarrhœa and enteritis in children under 2 years were reported in London, and the number of deaths from this cause during the month of August has had no precedent since 1914 (see Summary of Vital Statistics, p. 674). On the other hand, the mortality from the enteric fevers was below the yearly average. In the circular on Water Supplies just issued to local authorities the Minister of Health reminds them that, while there is no immediate cause for anxiety, the prolonged drought increases the risk of water-borne disease occurring. The prevalence abroad of cholera calls for special vigilance and the occurrence of any outbreak of diarrhœa, however mild, should lead to a critical examination of the water-supply. Attention is directed to chlorination as the best method of securing rapid and efficient sterilisation, and the process is described in useful detail in an appendix to the circular letter which we reprint on p. 671. Ex-service men may protest that chlorinated water in France did not taste agreeably, but it is not an essential part of the process to add more chlorine than is needed to oxidise the organic impurities.

THE Harveian oration will be delivered at the Royal College of Physicians of London at 4 P.M. on Tuesday, Oct. 18th, by Dr. Herbert Spencer.

Surgeon-Commander A. C. W. Newport, R.N., will accompany the Prince of Wales to India as personal medical officer.

It is probable that modern cholera prophylaxis will be based more and more upon rapid and labour-saving laboratory methods, such as the one described above, since efficient laboratory organisation is the mainspring of cholera control. In this respect the Egyptian Public Health Department is fortunate, for it can command the services of several officers specially trained in cholera work. This department has had a considerable experience in cholera detection and control, for both before and during the war its vigilance has been unrelenting, and it is mainly due to the organisation of the Central Laboratory in Cairo, under the direction of Dr. Charles Todd, that the introduction of cholera from Palestine during the period of hostilities was prevented and that so many minor epidemics in Egyptian villages were nipped in the bud. The absorption of the International Quarantine Board into the Egyptian Public Health Department is now considered probable. The Board, which has been for many years responsible for the control of Egyptian ports, and especially for the health conditions of the annual pilgrimage to Mecca, has been called upon to concert measures with the French authorities in Syria and the Palestine Government against the possible spread of cholera from Russia. The present Mecca pilgrimage having been declared free from infection, westward bound pilgrims will henceforward have to submit only to the normal period of quarantine at Tor in Sinai. It is presumed that cholera control stations will in future be established at Beirut in French Syria and at Kantara at the terminus of the Palestine railway, based upon the system elaborated at Tor.

AORTIC REGURGITATION FOLLOWING LETHARGIC ENCEPHALITIS.

THE mischief that may follow in the wake of lethargic encephalitis is proving to be extraordinarily varied, and the disease, which a few years ago was regarded as one with an almost exclusive affinity for the nervous system, is now known to be no respecter of other systems, such as the cardio-vascular. Dr. D. Paterson and Dr. J. C. Spence recorded in our columns [1] recently a series of 25 cases in children, treated at Great Ormond-street Hospital, in the majority of whom permanent after-results were left; only one-fourth made a complete recovery. In a recent note on the late sequels of lethargic encephalitis, Dr. H. F. Höst[2] has recorded the case of a workman, aged 18, who had previously been well. On Dec. 7th he developed intermittent diplopia. Examination by an oculist next day proved negative, but a couple of days later he felt unwell and chilly, and his left arm became painful. On Dec. 11th, when first seen by Dr. Höst, he complained of violent pain in the left side of the neck, and the left shoulder and wrist. The temperature was 38·5°C., but there were no paralyses, no swelling of any joint, and no sign of heart disease. Two days later there was a complete change in the clinical picture; the pain had vanished and he became very drowsy, sleeping all day and having to be awakened for meals. The temperature of about 38° C., in conjunction with the other symptoms, left little doubt as to the diagnosis of lethargic encephalitis, and he was sent to hospital. He was discharged on Jan. 7th, comparatively well, but still suffering from lassitude. Two days later Dr. Höst examined him and was surprised to find definite signs of aortic regurgitation. Over the second right intercostal space and the adjoining portion of the sternum there was a prolonged, soft, diastolic murmur, which began with the second heart sound and continued throughout almost the whole of diastole. There was no other sign of aortic regurgitation, such as a capillary pulse, with this exception: the diastolic blood pressure was 55 mm. There was no evidence of mitral disease. In young adults aortic regurgitation without mitral disease is generally regarded as the result of syphilis. But in this case there was no history of syphilitic infection, and no clinical sign of it. As the regurgitation had developed within a few weeks, during which the patient had suffered from a febrile condition undoubtedly due to lethargic encephalitis, the correlation of the two was very probable. This case is the more remarkable as it is usual, indeed practically the rule, for the mitral valve to be first attacked when an acute disease, such as pneumonia, angina faucium, acute rheumatism, and the like, gives rise to endocarditis.

TUBERCULOSIS AND PROSTITUTION.

IN a recent address before the Berlin Medical Society Dr. J. W. Samson[1] discusses the subject of tuberculosis and prostitution from observations which he commenced in 1911 on 1300 women under the control of the Berlin police. With the exception of Spillmann of Nancy, who at the International Congress of Tuberculosis in 1905 described tuberculosis as a venereal disease, secondary only in importance to syphilis and gonorrhœa, no previous writer appears to have dealt with the relations between tuberculosis and prostitution. Dr. Samson attributes this omission to two principal causes: in the first place to the mistaken belief that coitus with a tuberculous woman is of too transitory a character to enable infection to take place; and secondly, to the equally erroneous supposition that women suffering from tuberculosis would be unable to pursue their profession or attract any clients. As regards the first supposition recent observations with the tuberculin reaction have repeatedly shown that only a brief contact in the case of young persons is sufficient to produce tuberculous infection; and it should be remembered that the great majority of the prostitute's clientèle is composed of youthful persons. The supposition that tuberculous women would be unable to pursue their occupation only holds good in the last stages of the disease. Moreover, the great majority of the women are compelled to continue their unhappy calling because the progress of the tuberculous process unfits them for any arduous work. Dr. Samson found that although about 10 per cent. of the 1300 women studied had more or less active tuberculosis, only one-seventeenth of those in the first stage, one-fifth of those in the second stage, and one-third of those in the third stage, according to the Turban-Gerhardt classification, were in a poor state of nutrition and so likely to repel their clients. The main contingent of those affected with tuberculosis were women between the ages of 20 and 30, a time of life when the disease is most frequent in other occupations, and, what is of special importance from the epidemiological standpoint, when they are most likely to be attractive to the male sex. Dr. Samson remarks that it is difficult to understand why attention has not previously been given to the high incidence of tuberculosis among prostitutes in view of the large number of factors which favour its prevalence in this class of women, especially bad hygiene, inferior housing accommodation, alcoholism, and sexual excess. On the other hand, the prostitute has two distinct advantages over other women—namely, a lesser expenditure of energy owing to the absence of any regular or heavy employment, and a remarkably high income compared with that of other occupations, the average earnings of professional prostitutes aged from 25 to 40 in Berlin in 1910 being four to five times as high as those of women occupied in other ways. It is noteworthy that syphilis, which was present in at least two-thirds of the 1300 cases, had, with a few exceptions, no appreciable influence on the course of the tuberculosis and that the two infections ran their course independently. As regards the effect upon tuberculosis of alcoholism, which from time immemorial has been associated with prostitution, Dr. Samson found that though there

BRITISH ASSOCIATION AT EDINBURGH.

SECTION OF PHYSIOLOGY.

(Continued from p. 624.)

A joint discussion with the Section of Chemistry was held on

Oxidations and Oxidative Mechanisms in Living Tissues.

The discussion was opened by Prof. F. Gowland Hopkins, F.R.S., who dealt with the chemical aspect of the biochemical oxidation of fatty acids, sugars, and amino-acids, and gave an outline of the current views concerning the mechanism by which these oxidations are effected. Prof. Hopkins had recently isolated from tissues a dipeptide, one of the components of which was cystine, a sulphur containing amino-acid. The cystine portion of the dipeptide could also be converted to the cysteine or reduced form, and could thus act as a hydrogen acceptor. By so doing it enabled a peculiar form of oxidation to occur; water was decomposed, the hydrogen being taken up by the sulphur dipeptide, while the oxygen was available for oxidations. These changes were effected by the activity of a special enzyme which resembled the Schardinger enzyme present in fresh milk. If a mixture of milk, formaldehyde, and methylene-blue were warmed the formaldehyde was oxidised to formic acid, while the methylene-blue was reduced to the colourless hydrogen addition product. These simultaneous oxidations and reductions probably play a very important part in effecting tissue oxidations.

In the discussion which followed Dr. C. Lovatt Evans, referring to the great significance of the isolation by Prof. Hopkins of the formerly obscure sulphur derivative present in the tissues, commented on the fact that hydrocyanic acid, employed as a poison gas in the war, exerted all its physiological effects by depressing the oxygen usage of the tissues, and, significantly enough, was eliminated as sulphocyanide. It seemed extremely likely that its conversion into sulphocyanide in some way deflected the proper functions of the sulphur dipeptide. The neutral sulphur of the urine, which was also affected by cyanide administration, seemed to be a further indication in the same direction.

Prof. R. Robinson, F.R.S., and Prof. G. Barger, F.R.S., gave chemical analogies to oxidations occurring in the tissues. Prof. A. V. Hill, F.R.S., gave a short account of the relations of lactic acid to muscular contraction and heat production in presence and absence of oxygen.

The section paid a visit to the clinical laboratory of the Royal Infirmary, directed by Prof. J. Meakins. Demonstrations of the effect of resistance to, and of restricted volume of, breathing by the methods devised by Dr. J. S. Haldane and his collaborators were shown. An apparatus for the study of the psycho-galvanic reflex was also shown.

Prof. E. P. Cathcart, F.R.S., opened a discussion on

The Physiology of Heavy Muscular Work.

The problems concerned, he said, were of a complex nature, since not merely the muscular, but also the circulatory, respiratory, and nervous systems were involved in an intricate coördination. Psychic factors were of especial importance in the onset or masking of fatigue; collapse from overstrain as a consequence of muscular exertion was most commonly of cardiac origin. Work might be divided into three physiological types, positive and negative, as in raising and lowering a weight, and static, as in maintaining a weight. The latter was of considerable importance, and played a very large part in all very severe work. It was particularly potent in arousing subjective sensations of fatigue, and yet was associated with no greater metabolic breakdown than positive or negative work; probably a restriction of the circulation through the muscles was one of the reasons why static work is accompanied by such severe subjective effects.

Prof. Hill, referring to the contraction and recovery processes in muscle, said that it was essential in prolonged effort for the recovery process to keep pace with the breakdown processes accompanying contraction; under these circumstances the muscles were, so to speak, living on their income, whereas in brief but violent efforts they were living chiefly on their capital. He was convinced of the importance of static work because the duration of single muscle twitches was so short. The stiffness following heavy static work was also a marked feature. One reason why a short contraction was less efficient than a more prolonged one was that relatively more energy was required to alter the shape of the viscous muscle tissues quickly than to change it more slowly, just as greater energy was needed to stir treacle quickly than to stir it slowly. He also described an apparatus for the study of maximal work in human muscle.

Prof. H. Briggs described a method previously detailed in the *Journal of Physiology*, by which he had studied the degree of physical fitness of recruits. The method was also applicable to the detection of malingerers.

Dr. J. S. Haldane, F.R.S., gave a short communication dealing with the circulatory changes during exercise. In connexion with this part of the subject Prof. Hill resumed the discussion, and described how, by measurement of the velocity of the pulse-wave by the use of the hot-wire sphygmograph, some measure of the circulation rate could be obtained from the formula:—

$$\begin{array}{c}\text{Velocity of}\\ \text{pulse wave}\\ \text{(in M. p. sec.)}\end{array} = 3{\cdot}57 \Big/ \sqrt{\frac{\text{\% increase of volume of arteries}}{\text{per mm. Hg pressure.}}}$$

It is interesting to note that the pulse wave travels with an increased velocity during exercise, especially in older persons; in young individuals whose arteries are more elastic the change in velocity is smaller.

Prof. A. D. Waller, F.R.S., then described his well-known investigations on

The Physiological Cost of Muscular Work

as determined by measurement of the carbon dioxide output, and claimed that his simple technique gave results of greater accuracy than the other and more elaborate methods dependent on measurement of the oxygen intake. This statement was subjected to extremely severe criticism by Prof. Cathcart, and was also criticised by Prof. A. Krogh and Dr. Haldane. An interesting fact was brought out by Prof. Krogh—namely, that fatigue occurred more easily in subjects whose diet was largely composed of fat than in those whose diet contained large amounts of carbohydrate. With reference to the restriction of circulation in static work he had, contrary to expectation, been unable to obtain definite proof of this, though it was certain that static effort was less fatiguing if interrupted at short intervals.

Mr. E. Farmer, M.A., contributed an interesting paper at the close of the discussion dealing with the

Economy of Human Effort in Industry.

There were innumerable difficulties in the investigation of industrial fatigue, not the least of which was the difficulty of obtaining any true measure of fatigue. Constant coöperation and intercourse between the laboratory worker and the field or workshop investigator were necessary in all such investigations.

At a later meeting, papers on colour-vision were read by Dr. F. W. Edridge-Green and Dr. J. H. Shaxby. Dr. Edridge-Green showed that the effect of adding white light to any spectral colour was virtually the same as an addition of yellow. The reason was apparently because yellow is the most luminous component of white light. Dr. Shaxby described a method of testing colour discrimination.

apparatus for estimation of CO_2, found that analyses made at different times of the day showed a range of 8 mm. Hg tension of alveolar CO_2, and that these variations were not due to experimental error, but were directly related to the ingestion of food. Haldane had showed that respiration is so regulated as to maintain the alveolar CO_2 tension approximately constant, that the stimulus to the respiratory centre is the H-ion concentration of the blood, and that any factor raising the acidity of the blood will automatically increase pulmonary ventilation and so lower the CO_2 in the alveolar air and blood plasma. The effects of alteration in the reaction of the plasma, as in violent exercise or in diabetic coma, upon the alveolar CO_2 tension are well known, but that the pouring out of acid from the blood during gastric digestion and of alkali during pancreatic secretion should influence the reaction of the blood and so the alveolar CO_2, although a rational deduction, had not been experimentally verified.

We await with interest further evidence upon the reaction of the blood and urine in the series of cases investigated by Dr. Dodds, and would congratulate him upon a successful application of the deductive method of reasoning to an important physiological and pathological investigation, the results of which correspond so closely with those obtained by the fractional method of gastric analysis.

POST-SCARLATINAL MIDDLE-EAR DISEASE.

WHEN commenting[1] on the Annual Report of the Metropolitan Asylums Board we expressed regret that the final portion of Mr. T. B. Layton's report, consisting of "suggestions put forward for organising a service to prevent the occurrence of chronic ear disease as a sequela of the infective diseases," and containing recommendations now under consideration, had not been published. A large part of this valuable report on the otological work done at the North-Eastern and Western Fever Hospitals is directed to just this point, the prevention of chronic ear disease as a result of the infectious fevers, or rather of scarlet fever, for the few cases of ear discharge in the other fevers were not enough to justify any conclusions. Mr. Layton finds that there is a great divergence of opinion as to the proportion of cases that leave the fever hospitals with chronic inflammation of the middle ear; otologists appear to believe that they are very numerous, whilst the medical officers of fever hospitals consider that they are relatively few. Possibly both are right; the percentage is low, but the total is nevertheless large, owing to the immense number of cases of infectious fever passing annually through the Board's hospitals. Similarly, aural surgeons in general believe that the middle-ear suppuration occurring in scarlet fever is more severe than other forms, whereas epidemiologists hold the opposite view. Mr. Layton supports the latter from his experience of 12 months' work, and offers two principal explanations: that scarlet fever varies in its clinical type, so that severer complications *may* occur in other epidemics; and that the otologist does not often deal with the mastoiditis occurring during scarlet fever, but rather with the secondary infections which occur in ears previously damaged by the disease. We can hardly agree with his third explanation—namely, that the otologist stirs up the inflammation by surgical interference. Mr. Layton finds, and most otologists will confirm this, that early paracentesis of the inflamed drum is the best way to limit the number of cases of chronic otorrhœa. The problem is how to ensure that this is done as soon as it is required. Aural surgeons have advocated daily routine inspection of the drum in fever patients; Mr. Layton finds it takes about an hour to do 30 cases, which is at the rate of one minute for each drum, and that it would therefore take one man an eight-hour day to go through a hospital of 240 beds, even if one man could do such routine work. Neither does he think it practical that each medical officer should examine the ears of all his cases daily, as there is a constantly changing personnel, and he has obtained much better results by asking the officers and ward sisters to look out for the symptoms of early ear disease, especially pain and a sudden rise of temperature, and to report to the otologist. Mr. Layton performs the paracentesis without a general anæsthetic, chiefly to avoid the loss of time consequent on waiting for consent, and does not mention the use of any local anæsthesia. The treatment, once the ear has begun to discharge, contains nothing noteworthy, and it has been decided not to proceed to the removal of tonsils and adenoids during the children's stay in the fever hospitals; under these circumstances it is to be hoped that arrangements are made for the performance of this operation after their departure. For mastoiditis Mr. Layton performs a Wilde's incision, and considers this operation particularly useful in severe cases of scarlet fever; it appears that he only proceeds to antrotomy if the temperature remains raised or if the incision fails to heal. We look forward with interest to the publication of recommendations based on his experience.

THE WAR-BLINDED IN GERMANY.

Sir Arnold Lawson, in a recent issue of THE LANCET, related the scheme of re-education for the blinded sailor and soldier in operation at St. Dunstan's. There are about 4000 Kriegsblinde in Germany, 287 of them being natives of Silesia, and in a little brochure[1] which has reached us Dr. Kurt Uhthoff tells how, in the province of Silesia, the problem of the war-blinded has been faced. At first the help given was largely through voluntary agencies of which there were a large number. Now the war-blinded are under the care of a branch of the official administration. The pension in the case of a single man with no previous skilled employment amounts to about 4550 marks a year; not too much, it would seem, when the depreciation of the mark is taken into account. An essential part of the system is that each of the blinded men has a caretaker (Fürsorger) who reports on his needs to the local committee and makes it his special business to advise and help as to his training for employment. The result has been so far successful that at present only about one-third of the war-blind are without some sort of remunerative employment. These include, besides the usual employments of brush, mat, and basket making, typewriting, telephone operating, massage, and various other employments. Country settlements have been attempted but here the inevitable difficulties of housing soon became apparent. German experience agrees to a great extent with that at St. Dunstan's. Poultry-farming is one of the employments, but experience shows that this is hardly suitable for a single man. The writer agrees with Sir Arthur Pearson that those with a minute amount of vision are far more difficult to help than the totally blind. The latter goes so far as to say that a slight residue of vision is a positive disadvantage to man from the point of view of learning a trade. On the whole the problem seems to have been approached in Germany in much the same spirit as it has been at St. Dunstan's, but we suspect that the latter has the advantage in providing the communal life during the period of re-education. A special feature of the German scheme is the proposal to supply each blinded man with a trained dog to guide him on his walks, embodied in a law made last year. The training of the dogs—German sheep dogs and Airedale terriers are mentioned—is carried on at a Government institute and already some 2000 canine attendants are available.

---

[1] Über das Schicksal der Kriegsblinden und ihre Versorgung mit besonderer Berücksichtigung der Kriegsblinden Schles by Dr. med. Kurt Uhthoff. Halle. Pp. 103. 9.50 M.

and laboratories. Amongst them Italians and Americans are most numerous; the latter have reconstituted the "American Medical Association of Vienna," which in pre-war times occupied an important position in the university. It is intended to re-establish the English courses formerly controlled and organised by that association. Numerous medical men from the Scandinavian countries and Holland have also come to the city, where they find not only a courteous reception and excellent opportunities for study, but a rate of exchange greatly to their advantage—enabling them, indeed, to save money during a sojourn in this country. At present special post-graduate courses are proceeding in the clinics of oto-rhino-laryngology, ophthalmology, and skin diseases, and in the laboratories of the pathological and chemical institutes; all other institutes and clinics will shortly be completely ready for post-graduate classes.

Indirect Extension of the General Hospital.

The present financial situation of the State, which is not likely to improve for some time, makes it impossible to proceed with the old plan to erect the remaining clinics of the general hospital on their selected site. The old military hospital, however, is not now required for its original purpose; under the Empire Vienna, being the military centre of a large army, boasted an enormous garrison hospital, now practically unused. This old building can thus be converted at comparatively little cost, in order to accommodate a large number of institutes and offices of the general hospital. Thus the kitchen, the administrative offices, the disinfection plant, the laundry, and the nurses' home will be transferred to the garrison hospital, and the premises thus rendered vacant in the general hospital devoted to creation and enlargement of clinics. A number of wards containing patients not required for teaching purposes, and convalescents, will also be transferred; the neurological clinic already possesses a dependance in the garrison hospital, and the departments of dermatology and pathological histology are now in process of migrating. The change will be completed within a year. The clinical beds alone will then number over 2000, and scientific work will not, as hitherto, be hindered by lack of space.

Difficulties of the University in Innsbruck.

The medical faculty of the University of Innsbruck (capital of the part of Tirol left to Austria) is faced with a serious dilemma which threatens to stop its work completely. The hospital where the clinical patients are housed is supported partly by the provincial council, partly by the municipality, with only a small grant from the Government. These contributions have suddenly been discontinued, the municipality having denied its obligation to assist in the upkeep of a State institution. The provincial council followed this bad example, and the Government is unwilling or unable to carry the entire burden. Negotiations are now going on; a real deadlock would mean a severe blow to the medical life of this country. The medical organisation is, therefore, on the look out to intervene or to assist in a satisfactory settlement.

Impending Retirement of Prof. Choostek.

The intention of Prof. Choostek, the famous neurologist, to retire from clinical work, and the plan of the Government to discontinue his—i.e., the third—clinic for pathology and internal diseases, has caused uneasiness in medical circles. This excellent investigator and teacher commands great respect amongst his colleagues, and his decision has caused sincere regret. Attempts are being made to persuade Prof. Choostek to reconsider his decision; it is surmised that the Government has in some way offended the professor, and would like to use this opportunity to dispense with the cost of one of the clinics. It is hoped such a deplorable result will not be permitted to follow.

Sept. 6th.

Public Health Services.

COÖRDINATION OF PUBLIC MEDICAL SERVICE.

COÖRDINATION of the public medical services is a desirable thing to which we are very far from having attained. Uncertainty as to the future position of the guardians no doubt blocks the way, but that is no reason why the medical services at present directed by local authorities should not be unified. The Bradford Health Committee's proposals to unify all the medical work of the health and education committees by putting it under the control of one committee of the corporation should meet with approval. Many medical officers of health make similar recommendations. Thus Dr. E. W. Hope, of Liverpool, in his last report, in referring to this subject, says:—

> "It is an administrative blunder to break the continuity of health supervision so soon as the child reaches its fifth birthday and impose the obligation for the child's health upon a different body, constituted for a wholly different purpose, and by no means always appreciative of the health needs of the child."

Dr. Charles Porter, in his 1920 report for Marylebone, deals with the matter as it affects the Metropolitan boroughs. He refers to the quite unnecessary duplication of work, to cross-purposes and excessive correspondence resulting from the existing system, and says:—

> "In no part of the kingdom, indeed, is the divorce between the general public health work and school medical work so complete as in the Metropolis, and since it is impossible to see any justification for it on public health grounds, certainly, and probably also on economic grounds, it is difficult to see why either the central government authorities or the local authorities have for so long acquiesced in the arrangement."

Other anomalies in our existing system of health administration which lead to overlapping are to be found in the control of tuberculosis and the supervision of the midwifery service. Large urban districts charged with the administration of maternity and child welfare schemes do not control their own midwives, while it is now becoming more and more recognised that well-trained midwives may be invaluable helpers in such schemes. Antenatal work, the encouragement of breast-feeding, the prevention of ophthalmia neonatorum all suffer from the lack of unified control. Metropolitan boroughs are at the present time making a move towards better coördination of official and voluntary efforts with regard to tuberculosis and infant welfare.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

A GROUP OF METROPOLITAN BOROUGHS.

Kensington.

THE estimated population of the Royal Borough of Kensington in 1920 was for birth-rate 165,496 and for death-rate 164,177. The birth-rate during 1920 was 24·3, the death-rate 13·4, the infant mortality rate 81, the death-rate from phthisis 0·82, and from other forms of tuberculosis 0·27. Dr. J. Fenton tells us that one of the most important steps during the year has been "the establishment of an advisory committee to the maternity and child-welfare committee to assist the council in coördinating the work of the numerous voluntary bodies engaged on child-welfare work in the borough." There are seven centres and the borough has been mapped into seven areas with a centre in each. Five of the centres provide dental treatment. There is an infant clinic in addition, which Dr. Fenton thinks might usefully act as a treatment centre for the seven child-welfare centres. Whatever the future of local government in London this coördination of child-welfare work seems eminently desirable. One of the seven day-nurseries has been closed, and on this subject Dr. Fenton says: "The future of day-nurseries requires careful consideration, for it is open to question whether it would not be better and even more economical to spend money on keeping necessitous widowed and deserted mothers

CHILDREN'S ORTHOPÆDIC CENTRES.

IN view of the fact that some of the clinics established for the treatment of pensioners are now desirous of extending their work and including the treatment of crippled children, the Central Committee for the Care of Cripples have had under consideration the work of such clinics for the treatment of children by massage, remedial exercises, and electrical methods[1] and have drawn up the following report.

The types of children for whom such treatment may be suggested are:—

1. *Rickets.*—It is very doubtful whether physiotherapy is worth while. Minor cases are best treated at infant welfare centres by regulation of feeding and medicine and attention to hygiene. Major cases require either splinting or operation, or treatment in a residential institution where the hygiene and the diet are carefully supervised. Out-patient massage is waste of effort; it is impossible to give skilled massage to an infant.

2. *Infantile Paralysis.*—The treatment may be divided into (1) Prevention and correction of deformities: (*a*) splinting; (*b*) operative treatment; (*c*) use of walking apparatus. (2) Physio-therapy: (*a*) massage; (*b*) re-education of movement; (*c*) electrical treatment. These should be considered as a whole. In an early case splinting, massage, and electrical treatment of the appropriate muscles should be provided, followed at a slightly later stage by re-education of movement and by the provision of any necessary appliance. The scheme of treatment must be settled by a surgeon with special experience in this work, who should direct which muscles are to receive treatment and which movements require re-education. There is a tendency to consider physiotherapy as the panacea for infantile paralysis. This is not so. It has its uses, but must be applied thoughtfully as a part of the whole scheme of treatment. Only selected muscles and movements should be treated and exercised. It is easy by giving electrical treatment to the stronger muscles to produce rather than to diminish deformities. After two years from the date of onset of the paralysis physio-therapy has only very restricted uses. During the later stages, however, carefully thought out exercises to improve the power and control of muscles which have recovered but are not in active use, and to undo bad habits, may produce great improvement. It requires great experience and intelligence to draw up the scheme for such treatment. These cases more than any others should be under an orthopædic surgeon whilst under treatment. Treatment should in no case be indefinitely prolonged.

3. *Spastic Paralysis.*—These repay physio-therapy only in so far as they are capable of improvement by re-education. Massage and electrical treatment are useless. It may be said generally that the appropriate methods of re-education are not taught in the massage schools, so that a masseuse will not be able to deal adequately with a case of spastic paralysis unless she has preliminary and special instruction.

In all except very mild cases the treatment by re-education is only a part of the treatment, preliminaries being the reduction of the spasm by surgical methods such as tenotomy, division of nerves, division of posterior nerve-roots, and perhaps the provision of walking appliances. Many cases of spastic paralysis are so mentally deficient that they are unable to respond to any form of treatment.

4. *Scoliosis and Round Shoulders*, divisible into: (1) Mild postural cases. The essential element in these is not bone deformity or muscular weakness, but lack of proper muscular control and balance. Their cure is a question of physical education. They are best dealt with in small classes and by educational gymnastics. Such treatment is most easily given in the schools. Apparatus is not essential: if apparatus is provided it should be only of the simplest, the most valuable pieces being (*a*) reversible bench for balance work, and (*b*) a few rib stools. Plinths are not wanted. (2) Mild structural cases. It is essential that these should be under regular surgical supervision, as they are the type of case from which the bad scoliosis arises, and often arises very suddenly. Exercises for these require most careful regulation. The best exercises are, as a rule, those for improvement of control of muscle balance—i.e., educational. Splints for recumbency and supports for the spine may be required. (3) Severe structural cases. These require much the same treatment as the last class, but in many cases there is a tendency to treat by exercises children with fixed severe curves which are quite incapable of improvement. The number of bad cases of scoliosis among school children is relatively very small.

5. *Flat Feet.*—Flat fleet and talipes valgus are common in children. The first essential in treatment is to see that proper boots or shoes are worn. Boots that have been modified or are supported by a steel spring may be required. Subject to this, exercises are useful in a large proportion of cases. Class exercises in school are all that are required, except in a few special cases. No apparatus is required unless it is a skipping rope.

6. *Breathing Exercises* can be best done in classes in school. No apparatus is required.

7. *Bone and Joint Disease.*—It should be our aim to see that these cases are treated, as far as possible, in residential institutions while at the active stage. During later stages they require careful after-care, namely: (*a*) periodical surgical supervision to watch progress; (*b*) supervision to see that apparatus is worn and rules as to rest carried out.

The types of cases which require orthopædic supervision and treatment can therefore be divided into: (*a*) Those for whom class exercises only are required. These should be dealt with by special physical education classes in schools, and should not be brought to treatment centres apart from initial and periodic examinations. The treatment of these children in clinics interferes much with their schooling, and is unnecessarily expensive. (*b*) Those who require orthopædic treatment. This may include surgical supervision, splinting, surgical appliances and physiotherapy such as massage, exercises, and electrical treatment. These cases cannot be dealt with at a clinic at a school, but should be treated either in a hospital out-patient department, or if one is not accessible, in a centre which is virtually an outpost of the orthopædic hospital, and should be supervised by a surgeon trained in orthopædic work and in touch with the central hospital, which can deal with portions of the treatment which cannot be carried out at the centre.

Such centres should be: (1) Established only where a hospital cannot adequately carry on the work of the area. (2) Part of a complete scheme of orthopædic treatment for the area and properly coördinated with a hospital. (3) Under the surgical supervision of an orthopædic surgeon, who visits sufficiently often to exercise adequate supervision. He must be paid. (4) Coördinated with: School medical work—school medical officer should visit the clinic weekly and admit new cases; infant welfare centres; school classes for corrective exercises; Invalid Children's Aid Association.

The Central Committee for the Care of Cripples are willing to assist in the first organisation of a clinic or system of clinics, and particularly to assist in the selection of visiting orthopædic surgeons.

PÆDIATRIC RESEARCH FELLOWSHIP.—The John and Temple Research Fellowship has been established for a period of three years at St. Thomas's Hospital by Mrs. Temple Thomson. The Fellow elected receives £600 per annum and is required to act as chief clinical assistant in the Children's Department at St. Thomas's Hospital, as well as to undertake research work in some clinical or pathological subject especially connected with children. It is a full-time appointment.

---

[1] A report drawn up by the Central Committee for the Care of Cripples on the Organisation of Clinics for the Treatment of Children, 20, Berkeley-street, London, W. 1.

for the year 1920. The birth-rate rose from 13·6 in 1919 to 20·8 in 1920. The death-rate in 1920 was 15·2. The legitimate infant mortality-rate was 60, the illegitimate rate being 128. Dr. Bond expresses his satisfaction that the Holborn Council have approved the methods advocated by the Society for the Prevention of Venereal Disease. It is good to read in the account of the maternity and child welfare scheme that the Holborn Council are giving much attention to dental treatment. In addition to a dental clinic for expectant and nursing mothers, evening dental clinics have been arranged for men and boys not attending school and also for tuberculous patients. Of 16 cases of ophthalmia neonatorum notified, one of the children died, three left their former address, and the remainder were reported to have recovered.

SCHOOL MEDICAL SERVICE.

Colchester.

THE whole of the public health services of this ancient borough are under one executive officer. A blemish is the absence of a cleansing station. Dr. W. F. Corfield reports: "The time is not far distant when serious consideration must be given to the advisability of providing cleansing arrangements for children suffering from scabies." Naturally under these conditions it follows that impetigo "is one of the diseases that flood the minor ailments clinic." There is no nursery school in Colchester, and as children are admitted at the age of 4 the need for one is not regarded as pressing. A physical training organiser has recently been appointed with good results, and a class for defective speech training has been instituted. The number of children who underwent routine medical inspection was 1772. Of these 384 were referred for treatment, and in 201 cases treatment was obtained. 3120 dental inspections were made, and out of 1483 referred for treatment in 530 cases this was obtained. Out of 115 cases referred for treatment on account of visual defect, in 112 cases it was available.

Gloucestershire.

During the year about 15,000 routine examinations were made. Only 25 per cent. of the parents were present. Out of 7903 dental inspections 59 per cent. were found to require treatment, and in 61 per cent. of these cases it was obtained under the authority's scheme; 26 per cent. refused treatment, as against 31 per cent. in 1915; 218 children suffered from ear defects, in addition to 442 requiring observation; 315 cases of enlarged tonsils and 62 of adenoids required treatment, 3905 being kept for observation; 1402 children suffered from organic heart diseases, and 107 from anæmia. Definite pulmonary tubercle was found in 7 cases, and there were 13 suspected cases; 55 children were kept under observation for rickets. 79 per cent. of all defects requiring treatment received it, 21 per cent. of these being cured, 41 per cent. improved, 16 per cent. unchanged. Less than 50 per cent. of the children were unvaccinated. There is an excellent detailed summary of the year's work. Dr. J. Middleton Martin has made a comparative analysis of conditions for the pre-war period of 1908 to 1915, with the period 1916 to 1920. A comparison is made of nutrition in the two periods, nutrition in the second period being above average in 292 cases to every 100 cases in the first; while average heights and weights showed very little difference, in fact, above the age of nine the weights in the second period are 1 to 2 per cent. below those in the first. The method of estimating nutrition is interesting; the inspector makes a note on the card of each child as to the general impression conveyed, whether "above average," "average," or "below average." The comparative tables, which might have been analysed to a useful degree, are of little value, comprising as they do a mixture of various age and sex groups in no defined proportions.

Derbyshire.

Dr. Sidney Barwise, who is the school medical officer, acknowledges Dr. G. K. Thompson, his senior assistant, as the author of the report, a too unusual courtesy in regard to a quite usual condition. The report has been delayed by the preparation of the detailed and complex tables now required by the Board of Education. "There is a strong tendency for numerical records of treatment to overshadow prevention of disease." The number of children medically examined throughout the year was 29,342, as compared with 26,874 in 1919. Of these 26,534 were routine inspections; 6526 parents attended medical inspection; 457 children were temporarily excluded from school on account of tuberculosis, and 225 on account of their verminous condition. The number of children suffering from malnutrition showed a reduction this year. "The principal meal in colliers' homes is often about 2–2.30 P.M., and the children have to be satisfied with a makeshift. The want of a good midday meal is undoubtedly a principal cause." The fact that in 72·5 per cent. of invalid crippled cases the trouble began before 5 years of age emphasises the necessity for nursery schools. "It is the duty of our school nurses, as health visitors and inspectors under the Notification of Births Act, to visit each child regularly during the first five years of life, and already there have been many cases where incipient disease has been detected and checked through their vigilance. How much more easily and surely could this be done if the child attended a nursery school." As a result of the school nurses acting as nurses under the Maternity and Child Welfare Act, the proportion of salaries chargeable to the Education Committee has dropped from 33 to 23 per cent. The three dentists are assisted by five dental dressers. Sixty closures of schools, mostly for measles, were, as a rule, too late to prevent the spread of the disease. The ophthalmic work is well done so far as provision has been made. Two cases of xerosis with night blindness, cured on the vitamin theory with cod-liver oil, are noted. A half-tone block of tonsils and adenoids removed is of interest. Of 205 tonsils removed at the Derby clinic, 91, or 45 per cent., were demonstrated to be infected with tubercle bacilli. They were for the most part accompanied by enlarged glands which disappeared after operation. Further details of this investigation would be of interest. Dr. Barwise considers that the results of physical drill so far have been disappointing. He points out that the majority of deformities are preventable. With this object in view the authority has appointed a supervisor of physical exercises. This is an excellent report of work which, if allowed greater freedom, would rapidly advance knowledge.

VITAL STATISTICS OF LONDON

DURING AUGUST, 1921.

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the *notified cases of infectious disease* it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 8·5 per 1000 of the population, estimated at 4,531,971 persons in the middle of 1920; in the three preceding months the rates had been 9·6, 9·4, and 10·3 per 1000. Among the metropolitan boroughs the lowest rates from these diseases were recorded in Fulham, St. Marylebone, Hampstead, Holborn, Lambeth, Wandsworth, and Lewisham; and the highest in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, and Bermondsey. The prevalence of *enteric fever* was about equal to that in the preceding month; of the 43 cases notified during the five weeks ended Sept. 3rd, 6 cases belonged to Deptford, 4 to St. Pancras, 4 to Wandsworth, and 3 each to the boroughs of Kensington, Stepney, Poplar, Lambeth, and Greenwich. There were 32 cases of enteric fever under treatment in the Metropolitan Asylums Hospitals at the end of the month, against 18, 23, and 27 at the end of the three preceding months; the weekly admissions averaged 5, against 5, 4, and 5 in the three preceding months. The prevalence of *scarlet fever* was 20 per cent. less than in the

CHLORINATION OF POTABLE WATER:

CIRCULAR OF THE MINISTRY OF HEALTH.

THE rapid and efficient sterilisation of drinking water by means of treatment with chlorine is described in an appendix to Circular 241, issued by the Ministry of Health on Sept. 15th to local authorities.

General Principles of Chlorination.

Chlorine is most readily available in the form of chloride of lime (bleaching powder) which can readily be obtained commercially. This, if freshly made, should contain 33 per cent. of free or active chlorine. It loses its efficacy on keeping, especially during hot weather; but this loss may be retarded by the addition of 25 per cent. of quicklime. Samples of the bleaching powder used should be examined by a chemist to see that the proper amount of chlorine is present. Any deficiency in strength may be counteracted by an increased dose.

In order to be sure that all infective organisms are killed, the chloride of lime must be added to the water in such quantity that free chlorine will be available to the extent of at least one part per million of water. This will be effected by the preparation of a solution of chloride of lime consisting of 1 ounce of chloride of lime to 1 quart of water. This will suffice to treat 2000 gallons of a water which does not contain an excessive amount of mineral or organic matter.

If the water is very impure, discoloured, or contains much suspended matter, it should, if circumstances permit, first be clarified by the addition of from 2 to 8 grains per gallon of alum and an equal proportion of powdered whiting, and allowed to stand in a tank, from which it should be decanted to another tank for the addition of the chloride of lime solution.

Removal of the Taste of Chlorine.

After the addition of the chloride of lime, the water should, *if practicable*, be allowed to stand in an open tank for four hours before consumption. If this can be effected there will usually be no complaint of taste of chlorine in the water. If this cannot be effected the taste may often be removed by the addition of a small quantity of permanganate, sufficient to produce a very faint pink colour fading away in about 5 to 15 minutes; or, so far as the chlorine taste is concerned, by the addition of a solution of sodium thiosulphate (the hyposulphite of soda used in photography) in small quantities. The quantities of these preparations which are necessary to remove the taste can be quickly determined by practical tests. Wherever possible, in the case of a water-supply which is filtered, the chlorine solution should be added after filtration.

Adaptation of Method to Quantity.

There are various ways of adding the chlorine solution to the water. If it is a small supply, such as that from a cottage well, dip well, small spring, or land drain, the water will have to be pumped into some receptacle such as a tub, barrel, or tank cart, and the chlorine solution added by hand. Water should be allowed to stand for four hours in the open and then be distributed to consumers.

If it is a larger supply, corresponding methods, involving the adding of measured quantities of the chlorine solution by hand, will probably have to be adopted in the first instance, because it takes time to provide or arrange apparatus.

If the treatment has to be continued for any length of time, however, an improvement on this method is to provide a small tank to hold the chlorine solution, which is fed from a larger tank, and kept filled to a certain level by means of a ball tap or other similar contrivance. In this way, a constant level, and, therefore, constant pressure, is maintained in the small tank, which assists in regulating the flow. If this is fitted with a fine glass tube, having a controlling tap and a pressure gauge, the solution may be allowed to drip at such a rate as to pass the required amount per hour into the water, the rate of discharge of which into the reservoir is known. The tap should be so arranged as to drip over the point of discharge of the water into the reservoir. When the reservoir is filled, the chlorinated water should be allowed to stand for four hours before consumption, if practicable.

When the chlorine cannot be added to the water in the reservoir the solution may be injected into the rising or other main by means of a suitable contrivance, such as a pump driven by a turbine from the rising main, the amount of solution injected being proportionate to the rapidity of flow of water in the main, a definite relation being established between the two.

The tank containing the chlorine solution should preferably be of glass, in order that any failure in the supply may be detected at a glance.

Difficulties and Safeguards.

The continued use of chloride of lime, except where employed on a very large scale, and under skilled supervision, may give rise to difficulties in that it requires labour and constant attention, and it will probably be found that some other method of adding the chlorine will in the long run be preferable if the treatment has to be continued for an indefinite period. Various liquid preparations containing chlorine in known proportion may be employed, such as "Chloros," which contains from 10 to 15 per cent. of available or free chlorine and is prepared by the United Alkali Company, Liverpool. The liquefied gas can also be employed, and there are various forms of apparatus for effecting this automatically, also for using the dry chlorine gas or a solution of this in water.

Any mains, pipes, cisterns, or tanks which have contained polluted water should be emptied and disinfected. It will frequently be found, after the water mains, pipes, and cisterns have been disinfected by a strong solution, say, five parts per million, and after the use of chlorine, in the proportion of one part per million, for some days in the water, that the amount of chlorine may be reduced to one part in three millions, and risk of "taste" will then be reduced. Whether this can be done will depend on the course which the outbreak of disease takes, and on the results of analysis, bacteriological and chemical, of the water before and after treatment with the chlorine.

The appendix concludes by stating that in the case of a heavily polluted water it is well to make sure that some free chlorine is present after the addition of the solution to the water. This can be ascertained by the starch and iodide of potassium test, which is particularly sensitive if the water is at a low temperature; the materials for this test can be obtained in the form of compressed tablets. The use of poisonous metals in any apparatus dealing with the water whilst under treatment with chlorine must be avoided.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Attempts to Restrict the Number of Matriculations.

VARIOUS proposals have been made of late years with a view to checking the constant increase in the number of medical students in Vienna. The dissecting rooms and laboratories were more than crowded before the war, and latterly things have become worse. The formation of the new States in Middle and Eastern Europe, the increase of illness caused by the war, and the changed mentality of many millions of people, have necessitated a larger and better supply of qualified doctors; and nearly all the new medical students have flocked to Vienna, the old centre of learning, where are the best equipped institutes and the best teaching available for them. As a consequence the Viennese and other Austrian students began to be crowded out; moreover, the majority of the foreign students from Eastern Europe are Jews, who have been more or less expelled from Poland, Roumania, or Russia, and possibly religious bias has assisted the decision of the dean of the medical faculty to admit no more than 100 new first-year students to matriculation for this term, with the proviso that only if all Austrian applicants have been accommodated may the remainder ask for admission. This proviso does not, however, apply to students who have already had one term at the university, or to post-graduates; such students are encouraged to continue their studies. This restrictive measure is also justified by the small number of human bodies available for dissection and the very high prices demanded for animals—even frogs, mice, rats, and rabbits—used for experiments. Naturally its promulgation has not received unanimous support, as it is feared that the high standard of liberty hitherto enjoyed by the Vienna school may be discredited by its application.

Influx of Foreign Physicians.

Quite a number of foreign doctors have recently taken medical courses in Vienna and are now busily engaged in scientific and practical work in the clinics

HOUSING NOTES.

Building Guilds.

THE Government's refusal for a certain period to enter into further contracts to aid the building of houses has by no means quenched the interest appertaining to housing at the present time. Old problems have acquired a new liveliness; ideals arising out of the war have produced new methods. To these ideals Building Guilds owe their origin. Building Guilds stand for complete democratic control within the industry and for complete publicity as to costs, charges, and prices. The fact that work on 13 building schemes (two in London and 11 in the provinces) has been commenced shows that they represent a practical proposition. Mr. Ernest Selley, an independent investigator who has collaborated with Mr. Seebohm Rowntree and Captain Reiss in the past, has visited five sites involving the building of 986 houses; at three, many houses were nearly finished and the work was sufficiently advanced to provide a basis for a considered opinion as to the probable success of the Guilds. Informal inspections of the building operations were first made and the workmen questioned, later the Guild officials on the site were cross-examined impartially. All the workmen appeared to be working with a will, even in the absence of the foreman. The clerks of the works, the best judges, were all pleased with the output; some found that the output on Guild schemes are 25 per cent. above the average for similar work for other contractors. The standard of the work is high. Guilds reserve the right to pay the workmen full wages in wet weather or fine, in sickness or on holiday. In Manchester for the last quarter of 1920, in spite of much rainy weather, the money paid for time not worked was less than 1 per cent. of the total wages paid. No figures are available as to the actual cost, but Mr. Selley holds that in the schemes visited all the evidence goes to show that the final costs would be considerably below contract figures. For the Walthamstow Council Scheme for 400 workmen's dwellings the accepted estimate of the London Guild was about £36 per house less than the lowest estimate submitted by the private contractors. The Guild agreement provides that the price shall be the prime cost of material and labour at standard rates, together with an additional 6 per cent. to cover head office administration expenses, plant, insurance, and, if necessary, interest on borrowed capital. To this is added an allowance of £40 a house to enable the Guild to guarantee continuous pay to its workmen in all contingencies. Sir Alfred Mond, as shown by his speeches in the House of Commons, evidently prefers the contract system, but is willing to consider the Building Guilds if they can prove the claims made for them.

The Standard of Home-Making.

An old problem has come more into the light. Many local authorities have recently for the first time become responsible for the management of house property, and will doubtless come up against the problem of the neglectful and dirty tenant. Obviously, it is almost impossible under prevailing circumstances to make inquisitorial investigations as to the cleanliness of the present homes of the applicants for municipal houses; the war services of the men, the overcrowding, residence outside the area, hinder such inquiries. The Women's Section of the Garden Cities and Town Planning Association have recently issued a report on the management of working-class property by women, a feature inaugurated by Miss Octavia Hill in 1864. They find that where tenants dispossessed from old houses are provided for in modern dwellings, many of the incoming housekeepers have had no experience of using the new fittings. Some of the women have not known how to clean their porcelain-surfaced or painted bath or [illegible]ware sink, or how to manage their closed-[illegible] Not only could a woman deputy manager remedy this lack of knowledge, but a skilled and tactful adviser would be able to improve the standard of housekeeping and home-making which has been lowered by overcrowding and unemployment. The Section recommend that the London University, which now grants a degree in estate management, and the College of Estate Management, should recognise the special need for the management of working-class property and make any necessary provision. The best course of training, they consider, would be one which combines the studies arranged at the Household Science Department at King's College, the London School of Economics, and the College of Estate Management, all of which are linked up to the University of London. The report goes on to condemn the undesirable means—key-money, percentage fees on builder's bills, and other "payments"—which have been practised in order to make the management of lower grade properties a paying business.

"Zoning."

The spoiling of residential areas has long been with us; its cure—zoning—has only recently been mooted in this country. Probably few outside those intimately concerned with town planning have a very definite idea of the meaning of the word, although zoning of cities has been in operation in the United States since 1909, when Los Angeles established the first zoning ordinance. Zoning, as defined by the chairman of the New York (City) Committee on Districting, is "the creation by law of districts in which regulations, differing in different districts, prohibit injurious or unsuitable structures and uses of structures and land." St. Louis, U.S.A., affords an example of its practice. After 16 months' preliminary study of existing facts and probable tendencies the city was, in August, 1918, divided into five districts—first residence district for one-family houses exclusively; the second residence district for other dwellings and for tenements, hotels, institutions, &c.; the commercial district comprising important streets, not within the manufacturing part of the city, for stores and shops; the industrial district for all forms of industry not considered objectionable because of noise, odours, smoke, and dust; and the unrestricted district, chiefly along the railroad lines and the river front, which may be put to any use provided that nuisances dealt with under the existing laws are not created. Apparently the movement in favour of zoning in America derives much of its impetus from objection to the sky-scrapers which cut off light and air from too closely approaching neighbours. Other objections are the proximity of garages, with their inevitable workshops, to adjoining schools or of factories to houses. The motor lorry has enabled industrial concerns to fix their factories in the tract of residential districts; proximity to railroads is no longer necessary. Only by a lawsuit can the well-to-do protect themselves against the various forms of nuisances caused by industry; zoning affords protection and prevention for both poor and rich.

It is necessary to guard against the insidious encroachment of industry and business on residential areas; one factory or one shop brings others in its wake. Interruption of the quiet and peace of residential streets, the disturbance of sleep of children, nightworkers, or even other adults, the creation of dust by increased traffic or by dusty industries, are all arguments against allowing any encroachment on residential areas by businesses or industries. One boon which zoning would bring in the future, if not at present, is the saving of hours now spent in travel between work and home; more homes will in the future be within an easy walk of work. Zoning finds its easier application in the towns to be planned in the future; when applied to existing towns it would require to be adapted to existing conditions while serving to check undesirable tendencies.

To prevent injustice no alterations in the use of districts would be made unless a substantial majority of the property owners affected gave their consent, the final decision resting with the municipal authority.

at home with their children rather than on the support of day-nurseries." The council subsidises the Kensington District Nursing Association to carry out, under the instructions of the medical attendant, the treatment of cases of ophthalmia neonatorum. Every one of the 53 notified cases of this disease has been finally reported as cured without any appreciable loss of vision. In one case, however, which was not notified, the sight of one eye was completely lost and that of the other seriously damaged. The council have now arranged to take over the North Kensington Tuberculosis Dispensary and run it as a municipal institution—another wise move. The treatment of tuberculosis in South Kensington is carried out for the council by the Brompton Hospital, and it is hoped to arrange a satisfactory system for the examination of contacts and suspects. Dr. Fenton points out that a tuberculosis dispensary ought not to be a place for doling out bottles of medicine and cod-liver oil and malt, as was the tendency during the war, but ought to be more and more confined to cases requiring expert treatment and diagnosis.

Hampstead.

The estimated population of the Metropolitan Borough of Hampstead for 1920 was 91,519. The birth-rate was 17·1, the death-rate 9·4, the infant mortality rate 47·9, the death-rate from phthisis 0·45, and from all forms of tuberculosis 0·60. The infant mortality rate is very satisfactory even in a district which Dr. F. E. Scrase tells us "is almost entirely residential, the greater portion being composed of well-to-do people, with two districts situated on the east and west composed almost entirely of the working classes."

Like Kensington, the Hampstead Borough Council have been engaged in drawing up a coördination scheme which will utilise the efforts of all the voluntary bodies engaged in child-welfare work, including the Hampstead Council of Social Welfare. Dr. Mary Kidd, who is in charge of the pre-maternity clinics, reports that as the result of the agreement with the District Nursing Association, the nurses send up cases and the pre-natal work is growing rapidly. The dental clinic for nursing and expectant mothers is doing good work. Dr. Kidd thinks the allowance of milk to expectant and nursing mothers has enabled a larger proportion to feed their babies up to nine months and in this way has helped in the lowering of the infant mortality rate. Nine cases of ophthalmia neonatorum were notified. Eight cases made a complete recovery; particulars of the ninth are not given. The report contains an elevation of the first block of the South End Green housing scheme, the only one of many proposed which has fructified. The first block was expected to be ready for occupation in May, 1921. The scheme consists of 140 flats, 20 with one bedroom, 78 with two bedrooms, and 42 with three bedrooms.

Poplar.

The Borough of Poplar comprises the registration sub-districts of Poplar (population 55,503), Bromley (population 63,970), and Bow (population 40,203), and the estimated population of 1920 for death-rate was 159,776. The following were the principal statistics for the three districts compared with those for the County of London as a whole:—

	Poplar.	Bromley.	Bow.	County.
Birth-rate	33·13 ..	35·82 ..	32·77	26·5
Death-rate	14·73 ..	14·55 ..	14·96	12·4
Infant mortality rate ..	83·10 ..	75·85 ..	90·77	75·0
Tuberculosis death-rate	1·78 ..	1·57 ..	1·58	1·26

Dr. F. W. Alexander reports that 10 true cases of small-pox occurred during the year and that 3 of the patients from Bromley died. Four successful prosecutions for smoke nuisances were undertaken. The tuberculosis officer reports that the dispensary in Bow-road is unsuitable owing to noise and that the Council are negotiating for new premises. Surgical tuberculosis is dealt with by agreement with the London Hospital. An X ray apparatus is in constant use at the dispensary for diagnostic purposes. A proposed dental-clinic awaits the approval of the Ministry of Health. A "care" committee meets fortnightly, but no arrangements exist for finding employment for patients and the labour bureaus are of little or no value to the tuberculous patient. The council have now taken over the work of the Poplar Infant Welfare Association. The antenatal clinic is not a success as yet. Sixty-one cases of ophthalmia neonatorum were notified; 57 recovered, 1 died, 1 removed, and 2 were in hospital at the end of the year. A dental clinic was opened in April.

Wandsworth.

The estimated population in 1920 of the Metropolitan Borough of Wandsworth (for death-rate) was 316,990. The birth-rate was 21·03; the corrected death-rate was 10·36; the infant mortality rate was 64, to be compared with 86 for the previous decade; the death-rate from phthisis was 0·75 and from other forms of tuberculosis 0·18. The pulmonary tuberculosis rate "is much the lowest on record." Dr. P. Caldwell Smith quotes the remarks of the magistrate in dismissing a case brought for giving a false warranty for milk: "In my opinion the borough councils of London will never get things right till they one and all intimate that it is useless to prosecute until the law is put into a reasonable shape in this matter." X ray work and throat examinations are carried out at the tuberculosis dispensary at St. Thomas's Hospital. Little is apparently done for surgical tuberculosis. Dental treatment is provided for the tuberculous by an arrangement with the British Dentists' Hospital. "The greatest difficulty has been experienced in finding suitable employment for those who are well enough to do some work." Dr. Smith gives particulars of the state of health at the end of 1919 of the cases of active pulmonary tuberculosis dealt with by the dispensary during the six years 1913 to 1918. There were 1561 in all, of whom 331 removed; of the remaining 1230, 54·5 per cent. are dead, 15·4 per cent. are in an advanced stage, 6·8 per cent. are stationary, 23·3 per cent. have improved. Tuberculin is only being rarely used as a diagnostic and much less frequently than formerly for curative purposes. Wandsworth has a very complete maternity and child welfare scheme. There are seven infant welfare centres and it is hoped to open an eighth shortly. Till recently the council have sent confinement cases to the Clapham Maternity Hospital and private maternity homes. A new maternity home with accommodation for 23 patients was opened in November and is to be maintained by the borough council. The building was purchased as a borough war memorial, the amount required being raised by voluntary subscription. Sixty cases of ophthalmia neonatorum were notified. "Twenty-six cases were treated in hospital as out-patients, 11 as in-patients, and the remainder were treated at home. Three cases removed from the district before recovery and one died. In three cases the sight has been impaired." A "home help" has been engaged in connexion with one of the centres. She "is paid 30s. a week with outdoor uniform and overall, fares being allowed up to 2s. 6d. a week. She is required to work eight hours a day and do whatever is necessary in the home—Saturday afternoons and Sundays excepted. The mothers book her services for confinement or sickness and pay a contribution according to their means to the infant welfare centre. No money is paid by them to the home help nor are meals provided."

Holborn.

Dr. W. A. Bond submits his farewell report for 1920 after 26 years' work in the Metropolitan Borough of Holborn, and refers to the improvements which have taken place during his tenure of office. He mentions housing improvements, improvements in meat inspection, in scavenging, and the control of tenemented property. The death-rate went down from 24·4 in 1895 to 14·4 in 1913; the phthisis death-rate was 3·24 in 1895 and 1·13 in 1920; the infant mortality rate was 185 in 1895 and 66 in 1920. The population of Holborn is a declining one and is estimated at 39,676 prostate had been abandoned on account of high mortality and indifferent results. White, of America, had started a crusade of orchidectomy, and vasectomy was by some surgeons being substituted for it. It was becoming increasingly evident that, in spite of much writing and many statistics, no real progress was being made. In 1901 Freyer published four cases of suprapubic prostatectomy, and claimed to remove not only the intravesical projection but the whole of the enlarged prostate. There at once arose a controversy, partly in regard to priority and partly in regard to anatomical details of the operation that lasted for some years.

One of Freyer's colleagues writes of this part of his career: "Looking back on that controversy one cannot help thinking that, although much ink was spilt and some feelings hurt, it did much good. The operation was brought well into the notice of the profession and the points of difficulty in regard to the anatomy and physiology were thrashed out so that within a comparatively short time the operation was established on a firm surgical and anatomical basis. The operation of suprapubic prostatectomy, on the lines drawn up by Freyer, is now practised throughout the surgical world.

"What of the man who achieved so much, and who raised such keen controversy? Freyer had, more than any man I have known, the power of concentration on a single issue. It was possible for him to exclude from his mind other surgical subjects, and even for the time all by-paths to which the subject might lead. Add to this a restless energy and a great driving force, and we see the character of the man. Like many of his countrymen, Freyer's best efforts were made under the stimulus of opposition. Yet he made a conscientious hospital surgeon. His attendance at hospital and the care that he expended on his cases there, until failing health rendered him unequal to the strain, was an example to his junior colleagues. It was with genuine pleasure that he accepted the post of first president to the newly formed Section of Urology at the Royal Society of Medicine and his regular attendance, sometimes in spite of physical suffering, and his evident desire to help the work of the Section will leave a lively sense of gratitude in the minds of the members and officers of the Section."

In 1904 Freyer was awarded the Arnott Memorial medal for the original research in surgery incorporated in his various works on "Modern Treatment of Stone," "Enlargement of the Prostate"—which has passed through five editions—"Surgical Diseases of the Urinary Organs," and "On the Best Methods of Removing Large Calculi from the Bladder." The size of his surgical practice may be gathered from the fact that articles which he published bear such titles as "100 Operations for Stone without a Death" and "1000 Cases of Total Enucleation of Prostate for Radical Cure of Enlargement of that Organ." During the war he was placed on the consulting staff of the Queen Alexandra Military Hospital and the Indian Hospitals at Brighton. He had also been consulting surgeon to the Eastern Command and surgeon to King Edward VII. Hospital. In recognition of all this public work he was created K.C.B. in 1917. Sir Peter Freyer married Isabella, daughter of Robert McVittie of Dublin, who predeceased him in 1914; he leaves a son and a daughter, the latter of whom is the wife of Major J. D. Grant, V.C.

DR. Paul Uhlenhuth, sometime professor of hygiene and bacteriology in the German University of Strassburg, has been appointed director of the Institute for Experimental Therapy at Marburg, founded by E. v. Behring.

THE R.M.S.P. yachting steamer *St. Margaret of Scotland* will commence in October a series of holiday cruises, embracing calls at Madeira, Teneriffe, and Las Palmas, the round voyage occupying about 22 days. Calls will be made at the principal ports in the islands, and the stay in port permits of excursions being made inland to points of interest.

Correspondence.

"Audi alteram partem."

THE CASE FOR NATIONAL HEALTH INSURANCE.

To the Editor of THE LANCET.

SIR,—As an attack is being made on the capitation fee and possibly on the whole question of National Health Insurance, it is necessary that the whole case be carefully examined so that the advantages, the faults, or the defects may be properly treated and the responsibility rightly adjusted.

The medical service, on which the Acts practically hang, has been subjected to much criticism, and has been searched thoroughly for the bad things, and these have been fully advertised. In many quarters it is taken for granted that the panel doctor is not only hopelessly inefficient, but that he is a brutal hard-hearted bully. Such a view does not require refuting as it is so evidently outside common sense; but yet there is an atmosphere of distrust and questioning, amongst responsible people, which has to be dispelled. An intimate knowledge of the service compels the considered opinion that as a whole it is a very good general practitioner service, that it is improving, that it will continue to improve if given a fair chance. It has been carried on under very great disabilities which have certainly not received the same publicity nor recognition from the interested parties exploiting complaints. It was started amidst the most acute and bitter political acrimony, not only amongst the general public, but amongst the medical profession. This has gravely handicapped the service all through, and it is possible that the present campaign is a resurrection of the old hates, for the same parties are again prominent. It may appear somewhat of the nature of an appeal ad misericordiam, but yet it has to be recognised that the conditions of the service, especially in an industrial area of London, are very trying. Of necessity there must be evening consulting hours which practically exclude the doctor from family and social life, or from recreation. His services are on tap at all hours, day and night. Any time he may take off is at risk of complaint. No citizen in the community occupies the same position as to hours of labour or demands for his services as the panel doctor. This does require recognition when the question of remuneration is considered. These disabilities are inherent to the service, but there are many others capable of reasonable adjustment.

As a whole the insured person is pleasant to serve and considerate, and in general the proper relations of trust between doctor and patient are established. There is practically no malingering, but a small section makes unreasonable demands. This section is naturally a noisy one, and has been consistently used by politicians, by the less responsible press, and by inefficient administrators, much to the prejudice of the service and adding considerably to the difficulties of the doctor. Again, there is the insured person who has not grasped the principle of insurance, and thinks he is being badly used because he "has been paying in and getting nothing out." Somehow he seems to think the doctor is the cause, and, if he reads the daily press, he becomes quite certain of it. There is also the "superior person" who tattles about "charity" and expects all the frills of the West End. It can be readily understood how such agents may be used to raise opprobrium on a genuine service, and how difficult it has been for the doctors to wear down a campaign carried on with deliberation for nine years. There is ample evidence, however, that the insured person is slowly but surely appreciating the value of the service.

An inquiry into the working of the service is being asked for. The medical profession would welcome an honest investigation, but their experience compels

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING AUGUST, 1921.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated civil population, 1920.	Notified Cases of Infectious Disease.												Deaths from Principal Infectious Diseases.									Deaths from all causes.	Death-rate per 1000 living.
		Enteric fever.	Other continued fevers.	Small-pox.	Scarlet fever.	Diphtheria.*	Erysipelas.	Poliomyelitis and polioencephalitis.	Encephalitis lethargica.	Cerebro-spinal fever.	Puerperal fever.	Total.	Annual rate per 1000 persons living.	Enteric fever.	Small-pox.	Measles.	Scarlet fever.	Whooping-cough.	Diphtheria.*	Diarrhœa and enteritis (under 2 years).	Total. * Including membranous croup.

preceding month; this disease was proportionally most prevalent in Hackney, Finsbury, the City of London, Shoreditch, Bethnal Green, Stepney, and Bermondsey. The Metropolitan Asylums Hospitals contained 3108 scarlet fever patients at the end of the month, against 3375, 3621, and 3722 at the end of the three preceding months; the weekly admissions averaged 467, against 507, 606, and 567 in the three preceding months. The prevalence of *diphtheria* was 16 per cent. less than in July; the greatest proportional prevalence of this disease occurred in Hackney, Finsbury, Shoreditch, Bethnal Green, Stepney, Bermondsey, and Battersea. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 2121, 1896, and 1969 at the end of the three preceding months, numbered 1709 at the end of August; the weekly admissions averaged 209, against 241, 235, and 250 in the three preceding months. *Erysipelas* was proportionally most prevalent in Paddington, Fulham, Finsbury, the City of London, Bethnal Green, Southwark, and Bermondsey. Of the 13 cases of *poliomyelitis* or *polioencephalitis*, 2 belonged to Fulham and 2 to Lewisham. Five cases of *encephalitis lethargica* were notified during the month, against 18, 10, and 9 in the three preceding months. The notified cases of *cerebro-spinal fever* numbered 9, against 11, 5, and 7 in the three preceding months. The 38 cases of *puerperal fever* included 6 in Lambeth, 5 in Islington, 4 in Chelsea, and 3 in Woolwich.

The *mortality statistics* in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ended Sept. 3rd, the deaths of 4615 London residents were registered, equal to an annual rate of 10·6 per 1000; in the three preceding months the rates had been 11·2, 9·4, and 9·8 per 1000. The death-rates ranged from 5·9 in the City of London, 6·4 in Hampstead, 7·5 in the City of Westminster, 7·8 in Lewisham, 8·5 in Stoke Newington, and 8·6 in Paddington, to 12·6 in Southwark, 12·8 in Shoreditch and in Bermondsey, 13·0 in Poplar, 13·2 in Stepney, 13·3 in Deptford, and 14·3 in Bethnal Green. Nine deaths from *influenza* were registered during the month, against 77, 30, and 15 in the three preceding months and an average of 32 in the corresponding period of the five preceding years. The deaths from the *principal infectious diseases* given in the table numbered 838; of these, 7 resulted from enteric fever, 24 from measles, 13 from scarlet fever, 56 from whooping-cough, 80 from diphtheria, and 658 from diarrhœa and enteritis among children under two years of age. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in the City of Westminster, Hampstead, Stoke Newington, Holborn, and the City of London, and the highest in Shoreditch, Bethnal Green, Stepney, and Poplar. The 7 fatal cases of enteric fever were 2 fewer than the average. The 24 deaths from *measles* were only one-half of the average number; of these, 8 belonged to Stepney and 8 to Poplar. The 13 fatal cases of scarlet fever exceeded the average by 7; of these, 2 belonged to each of the boroughs of Fulham, Islington, Hackney, and Camberwell. The 56 deaths from *whooping-cough* were double the average number; the greatest proportional mortality from this disease occurred in Paddington, Finsbury, Bethnal Green, Poplar, and Battersea. The 80 fatal cases of diphtheria were 33 in excess of the average; this disease was proportionally most fatal in Kensington, Finsbury, Shoreditch, Poplar, and Bermondsey. The deaths from *infantile diarrhœa* numbered 658 and exceeded the average by 401. This is the largest number of deaths from infantile diarrhœa recorded in London in August since the corresponding period of 1914 when they numbered 711; the greatest proportional mortality from this disease occurred in Shoreditch, Bethnal Green, Stepney, Poplar, Southwark, Lambeth, and Deptford. In conclusion, it may be stated that the aggregate mortality in London during August from these principal infectious diseases was 152 per cent. above the average in the corresponding period of the five preceding years.

THE LATE DR. WILLIAM BARNETT BENJAFIELD.—Dr. Benjafield, a retired practitioner, who died on Sept. 13th in his sixty-fifth year, was a graduate of Edinburgh University, where he qualified M.B., C.M. in 1882, in the same year taking the M.R.C.S. Eng. He was a man of wide interest in the profession, having been physician to the Tottenham and Edmonton General Dispensary, assistant demonstrator of anatomy at the University of Edinburgh, and house surgeon in the ophthalmic wards of the Royal Infirmary. Dr. Benjafield was at one time specially interested in the treatment of consumption under the Poor-law, contributing a paper on the subject to the *Poor Law Officers' Journal* in 1902.

non-protein nitrogenous bodies, provided the patient be eating, and the kidneys not properly working? And how do the amino-compounds (and allied bodies), absent in health, but present in the urine in these cases get into the urine? They must come in part at least from the blood. And how is their presence in the blood explained, except by an insufficiency of the liver?

Recognising Dr. Mackenzie Wallis as an authority on this matter, I have just looked up his recent article, the Toxæmias of Pregnancy.[1] I find he says much the same as the writer of THE LANCET article. This is what he says: "In toxæmias of pregnancy the results of an analysis of the blood show no striking deviations from those found in normal pregnant women. The blood urea content is usually within the normal limits. . . . The same applies to the sugar in the blood. . . ." But he says not a word about any other non-protein nitrogenous body. Throughout his article his blood test refers for the most part to the discovery of the urea content. Of course, if the patient is eating and the liver not functioning, one cannot expect as much urea to be formed as would be the case in the normal. But unless one excludes the presence of other non-protein nitrogenous bodies that may possibly be in the blood (and may possibly cause the fits), or has shown they do not occur in greater quantity than in health (Bayliss[2]), the categorical statement that in the pre-eclamptic state there is an absence of a definite nitrogenous retention seems to me unwarranted and misleading. Because, you know,[3] the occurrence of the toxæmias of pregnancy and of eclampsia, after all, may not be due to the wonderful "toxin or toxins" of which everyone is speaking. In any case, such a statement as that I have referred to coming from THE LANCET seemed to me to require clearing up, or qualification. The statement may be perfectly correct. If it is, then I can only suppose that the functions of the liver are limited to the storing of carbohydrate, the formation of bile, and possibly others, but that its supposed urea production is an exaggeration. And I must suppose when an Eck's fistula is made in the dog and the animal is given meat that the ensuing convulsions are the result either of a depletion of carbohydrate in the liver (as Prof. Harding suggests is the cause of pernicious vomiting[4]), or that it is the result of an experimental error, and in any case is to be neglected.

I am, Sir, yours faithfully,
R. H. PARAMORE, F.R.C.S. Eng.

Rugby, Sept. 17th, 1921.

VERONAL AGAINST SEA-SICKNESS.

To the Editor of THE LANCET.

SIR,—Dr. T. Zangger's experience (THE LANCET, Sept. 17th, p. 630) agrees with my own, though, fortunately, mine was not acquired in my own person. In 1912, while acting as surgeon in the Union Castle Co., I had an exceedingly troublesome case of sea-sickness in a woman who was previously suffering from the vomiting of pregnancy. There were several other doctors on board and one of them (I believe Dr. Ashe of Kimberley) advised me to try veronal. I did not carry any in stock but managed to collect enough from passengers to go on with. I had had no previous experience of this drug other than as a sleeping-draught, so was afraid to push it. As long as the patient was under the influence of veronal the vomiting ceased and when it recurred it was checked by a further dose. The patient arrived safely though very weak. A second pregnant woman in a later voyage became sea-sick; I gave her a 10-grain dose on my morning round and by 5 o'clock she was quite cheery. A second attack a few days later was checked permanently by one dose. As far as I remember, out of all the cases in which I used the drug (and I used no other) only one failed to respond to a 10-grain dose.

My experience of treating sea-sickness was not nearly as large as I should have expected, as most people seem to prefer to suffer in solitude unless the attack is very severe.

I am, Sir, yours faithfully,
Clevedon, Somerset, Sept. 19th, 1921. R. L. WASON.

TRYPANOSOMIASIS:
A NEW METHOD OF TREATMENT.

To the Editor of THE LANCET.

SIR,—With reference to the paper on this subject read by Dr. C. H. Marshall, senior medical officer to the Uganda Protectorate, at the Royal Society of Tropical Medicine and Hygiene (THE LANCET, June 4th, p. 1185), I am surprised that neither in this paper nor during the subsequent discussion was any mention made of the fact that this method of treatment was suggested as far back as 1907 by Thiroux and d'Aufreville, who wrote[1] as follows:—

> "There is reason to conjecture that sero-therapy will not give results in meningeal trypanosomiasis unless the antitoxin is injected into the spinal canal or cerebral substance, as has been done for tetanus antitoxin."

No statement can be clearer than this. During 1909 a review[2] under the heading "A Suggestion for Treatment," by Dr. Andrew Balfour, goes on to say:—

> "In a memorandum headed 'The Treatment of Sleeping Sickness: A Suggestion,' forwarded to the Bureau by Colonel Mathias, R.A.M.C., President of the Sudan Sleeping Sickness Commission, and dated Nov. 17th, 1908, Dr. Andrew Balfour draws attention to the results obtained by Drs. Mackenzie and Martin, in the treatment of cerebro-spinal meningitis' by their method of introducing locally by spinal puncture a highly immune serum which they had obtained from the blood of patients who had recently recovered from the disease or, as in two successful acute cases, who were still running a course. The latter were injected with their own sera taken on the sixth and seventh day of their illness respectively.'
>
> "He suggests a similar use of serum-therapy in cases of trypanosomiasis. He mentions some points in which the diseases resemble one another. He asks if in sleeping sickness the cerebro-spinal fluid is a locus minimæ resistentiæ, does it lack trypanocidal substances? He proposes a combined therapy, the trypanosomes being attacked in the blood by some of the more promising of our present drugs, in the cerebro-spinal fluid by the injection of the patient's own serum or the serum from a case improving under treatment, obtained by defibrinating and centrifuging the blood.
>
> "Dr. Balfour's suggestion is well worth attention. As appears more than once in this number many cases have been met with in which trypanosomes persisted in the cerebro-spinal fluid when they could no longer be found in the blood or glands. Martin and Lebœuf found in one instance that tartar emetic, while it cleared the blood of parasites, was without effect on those in the cerebro-spinal fluid. If the action on the parasites is direct this might indicate that the drug does not readily permeate the meninges, and hence is never present within them except in a more dilute state than elsewhere in the body. That this may be so is suggested by Nierenstein's observation that arsenic was absent from the cerebro-spinal fluid of an injected donkey on the first day but appeared on the second. If the action of the drug is indirect the want of trypanocidal substance may be due to the poverty of the cerebro-spinal fluid in cellular elements, as Balfour suggests."

Dr. Andrew Balfour, therefore, went a step further when he suggested that the blood serum of patients under treatment with some trypanocide should be used for intrathecal injection. It will be observed from these passages that Prof. Halliburton's expression that "he took exception to scientific workers remaining in the clouds and avoiding propositions of practical importance" is by no means accurate; for it is obvious that the resistance of the meninges against permeation by curative agents introduced in the blood stream was prominently borne in mind by the observers

Each scheme should be framed with consideration for property rights; if, after this, individual owners feel themselves aggrieved, these grievances cannot be allowed to stand in the way of the public ideal.

In New York City the zoning ordinance has prevented depreciation in the value of property; areas which had been practically abandoned for several years by good-class residents have been rehabilitated. During the four and a half years of its adoption little disapproval has been shown, while no significant changes have been made in the ordinance itself.

MEDICINE AND THE LAW

Shell-shock and Perjured Evidence.

IN the case of a man sentenced to six months' imprisonment at the Central Criminal Court for perjury, the prisoner's counsel urged in mitigation of his offence that, having been blown up by a shell at the front, he suffered from a diminished sense of responsibility. The perjury alleged had been committed in the Divorce Court where, in seeking a decree, he had sworn that he had not had relations with his wife, or lived with her since 1916. It was, however, conclusively proved from a letter produced that he had visited her often since, when on leave. Mr. Justice Acton said that it would be a dangerous principle if it were to be laid down that injuries received by a man in defence of his country excused him from the consequences of such an offence. The prevalence of perjury in the Divorce Court was also referred to by the learned judge. In comment it may be observed that the effect in diminishing self-control and sense of responsibility attributable to shell-shock, wounds, and the strain of war, is, no doubt, considerable. It can, however, well be understood that neither a judge nor a jury would attach great weight to such an explanation in the case of perjury committed by a man in his own interest, in the circumstances of deliberation and reflection attaching to evidence in a court of law.

Rex v. Starkie.

At the Central Criminal Court R. W. Starkie, a medical practitioner who had held appointments under the police and under the St. Pancras Board of Guardians, was convicted and sentenced to nine months' imprisonment on a charge of administering to a woman, or causing to be taken by her, noxious things with intent to procure miscarriage. On three counts, charging the prisoner with using instruments to procure miscarriage upon three other women, he was acquitted. Sir Edward Marshall Hall, K.C., who defended, intimated that there would be an appeal referring in particular to the judge's ruling that the charge relating to the administering of drugs, upon which the prisoner was convicted, could be taken with the charges of using instruments. This was the case in which urgent requests by the committing magistrate and by counsel for the prosecution were addressed to the press to the effect that the names of the women witnesses, the subjects of the charges tried, should not be given in the newspapers. This does not imply that there was secrecy as to their identity, their names being given in court in the usual way. The publication of the names in the press was considered undesirable on account of the importance of securing, as witnesses in cases of the kind indicated, women who might be deterred from giving evidence by dread of the usual publicity. In his summing up Mr. Justice Acton referred to charges of the class under consideration as of deep seriousness to the defendant, possibly involving for him social, professional and financial ruin, and at the same time as of hardly less importance to the community. Cases such as this are admittedly insidious and difficult to prove.

The Traffic in Cocaine.

A man, 23 years of age, described as a pugilist, and a woman, 21 years of age, were sentenced recently at Bow-street for being in unlawful possession of cocaine, the former to a term of six months' hard labour, with three months in addition if he should fail to pay a fine of £200, and the latter to one month's imprisonment. The case was of the usual kind, the man having been seen by a detective-sergeant handing something to the woman at the corner of a street near Leicester-square. Upon the detective arresting him the man dropped three packets of cocaine and the woman in like manner tried to get rid of a single packet. Hardly a week passes without similar cases being reported, and it is to be regretted that the police seem unable to check the illicit traffic in the drug at, or nearer to, its source. The persons arrested appear nearly always to be the last links in a chain of distributors, operating in the streets or in more or less disreputable bars, the early closing of the latter driving them, no doubt, to deal largely in the highway where, at any rate, they are liable to observation. In many cases it is a man who carries a small stock of cocaine in packets, and hands one or two packets at a time to a woman, who may or may not be the ultimate consumer. The profits appear to be sufficiently large to tempt those concerned in retailing small quantities to run considerable risks, but it should not be beyond the ingenuity of the police to track out the traders who at present work in comparative security.

Obituary.

SIR PETER JOHNSTON FREYER, K.C.B., M.D., M.CH.R.U.I.,

LATE LIEUT.-COLONEL I.M.S.; CONSULTING SURGEON TO THE QUEEN ALEXANDRA MILITARY HOSPITAL AND TO THE EASTERN COMMAND.

THE death of Sir Peter Freyer on Sept. 9th, in his seventieth year, will remind surgeons the world over how it came about that litholapaxy and suprapubic prostatectomy are to-day firmly established as the operations of choice in vesical calculus and enlargement of the prostate.

The eldest son of Samuel Freyer of Selerna, Co. Galway, Peter Johnston Freyer was educated at Erasmus Smith's College, Galway, afterwards studying medicine at Dr. Steevens's Hospital, Dublin, and at Paris. In 1872 he graduated B.A. at the Royal University of Ireland with first-class honours and gold medal. Two years after he took his M.D. degree, again with the highest distinction, as well as the M.Ch. and L.M. Later he received an honorary M.A. In 1875 Freyer entered the Indian Medical Service, obtaining first place in open competition, and was lent to the Government of the North-West Provinces, acting first as civil surgeon at Moradabad, and afterwards at Bareilly, Allahabad, Mussoorie, and Benares, becoming surgeon to the Prince of Wales's Hospital at the last-named. He was appointed medical officer to the Lieutenant-Governor of the North-West Provinces and Oudh, and subsequently to the late Nawab of Rampur.

In India Freyer was interested in two widely different diseases, cataract and stone, both very common in the practice of a civil surgeon. It was soon after he went to India that Bigelow's operation of crushing stone in the bladder and removal at one sitting became known. The operation was not well received by Bigelow's colleagues in America, and it fell to two great Irishmen in the I.M.S., Keegan and Freyer, to place the operation in the position that it deserved. In 1894 Freyer was deputed by the Indian Government to attend on their behalf the International Medical and Surgical Congress at Rome.

After retirement from the Indian Medical Service in 1896 with the rank of honorary colonel, Freyer came to London, and two years later was appointed surgeon to St. Peter's Hospital for Stone. Prostatic surgery was then at a low ebb. McGill's operation for the removal of the intravesical portion of the enlarged

ROYAL ARMY MEDICAL CORPS.

Temp. Maj. J. J. Abraham relinquishes the actg. rank of Lieut.-Col.

Capt. J. A. W. Ebden, from Res. of Off., R.A.M.C., to be Capt.

Lieuts. (temp. Capts.) to be Capts: W. O. Holst, D. F. Panton, L. C. Goument, C. P. Chambers, and G. E. MacAlevey.

TERRITORIAL FORCE.

Maj. G. R. Livingston, having attained the age limit, is retired, and retains the rank of Maj., with permission to wear the prescribed uniform.

Maj. F. Gracie resigns his commn. and retains the rank of Maj., with permission to wear the prescribed uniform.

The following resign their commns. and retain their rank: Maj. W. J. Mackinnon and Capts. E. N. Thomson, W. Cullen, D. Campbell, and E. McM. Dunlop.

INDIA AND THE INDIAN MEDICAL SERVICE.

The King has approved the retirement of Lieut.-Col. F. J. Dewes.

Lieut.-Col. J. C. H. Leicester, professor, Medical College, Calcutta, has been granted leave. Maj. F. W. Cragg officiates as Director, Central Research Institute. Maj. D. Heron has been posted as Agency Surgeon at Meshed and Assistant to H.M. Consul General and Agent to the Government of India in Khorasan. Lieut.-Col. G. Fowler, on return from leave, is re-posted to Akola District. Maj. J. Taylor, officiating sanitary commissioner, has been placed under the direct orders of the Government of India. Lieut.-Col. J. B. Christian has been posted as Second Physician, J. J. Hospital, Bombay. Lieut.-Col. S. H. Burnett has been posted as Surgeon Superintendent, St. George's Hospital, Bombay. On return from leave Lieut.-Col. H. A. F. Knapton has resumed the duties of Superintendent of Matheran and Presidency Surgeon, First District, Bombay. Maj. M. A. Rahman has been posted to the United Provinces. Maj. D. Coutts has been appointed to collateral charge of duties of Civil Surgeon and Lecturer on Midwifery and Medical Jurisprudence, Médical School, Amritsar. Lieut.-Col. C. B. McConaghy, on return from leave, has been posted as Agency Surgeon, Bhopal. Maj. J. R. J. Tyrrell, on return from leave, has been posted as Agency Surgeon, Bundel Rund. Maj. F. E. Wilson, on reversion from military duty, has been posted as Residency Surgeon and Chief Medical Officer, Baluchistan. Maj. H. H. Thorburn, who has been officiating in the last-named appointment, will, on relief, take over the Civil Surgeoncy, Quetta, vice Capt. J. B. Hance, who will be posted as Consular Surgeon, Mohammerah.

MESOPOTAMIA HONOURS.

The King has made the following appointments for services during the operations in Mesopotamia.

The Most Excellent Order of the Indian Empire.—To be additional Companions: Col. A. H. Morris, Lieut.-Cols. A. E. Berry and M. MacKelvie, Maj. (actg. Lieut.-Col.) H. W. Illius.

The Most Excellent Order of the British Empire.—To be Officers of the Military Division: Maj. A. S. Arthur, Capt. and Bt. Maj. A. MacD. Dick, Capt. W. A. M. Jack.

MENTIONED IN DESPATCHES.

Royal Army Medical Corps.—Lieut.-Col. G. J. Houghton; Lieut.-Cols. and Bt. Cols. T. C. Mackenzie, H. H. Norman; Maj. A. S. Arthur; Capt. (actg. Maj.) C. M. Gozney (killed); Capts. H. C. Godding, A. N. Minns, and C. H. K. Smith.

Indian Medical Service.—Lieut.-Cols. A. E. Berry, M. Mackelvie; Maj. and Bt. Lieut.-Col. (Temp. Col.) W. H. Hamilton; Maj. (actg. Lieut.-Col.) H. W. Illius; Majs. J. W. H. Babington and A. A. C. McNeill; Capt. and Bt. Maj. A. MacD. Dick; Capts. E. Cotter, W. A. M. Jack, and J. W. Pigeon (killed in action).

Indian Medical Department.—2nd Cl. Asst. Surg. H. E. Gillson; 4th Cl. Asst. Surg. H. C. Halge; Sub-Asst. Surg. (Civil) Kesar Singh; 1st Cl. Sub-Asst. Surg. Waman Hari Supekar; Maula Bux.

THE R.A.M.C. ROLL OF HONOUR.

The official list of the names of officers of the R.A.M.C. who laid down their lives in the Great War was published in March last and an analysis of the 709 names, according to rank, was given in our issue of March 12th. A roll of honour has now been published by H.M. Stationery Office, price 5s., containing the names of non-commissioned officers and men. There are over 5500 names of the Regular Army and Territorial Force arranged alphabetically, and the document forms part 79 of "Soldiers who Died in the Great War, 1914-1919."

Medical News.

University of London.—The following awards of medical entrance scholarships and exhibitions have been made by the London Inter-Collegiate Scholarships Board:—

University College.—Bucknill Scholarship.—A. S. Wesson, Merchant Taylors' School. Additional Bucknill Scholarship.—M. Barer, King Edward's Sch., Birmingham. Medical Exhibition.—Violet H. Comber, Univ. Coll.

Westminster Hospital Medical School.—Natural Science Scholarship.—G. A. H. Norman, E. Lond. Coll.

London (Royal Free Hospital) School of Medicine for Women.—St. Dunstan's Medical Exhibition.—Muriel F. Prout, Sydenham Secondary Sch. Mrs. George M. Smith Scholarship.—Winifred A. Ladds, Bromley High Sch. Isabel Thorne Scholarship.—Evelyn M. Pakeman, St. Paul's Girls' Sch. Mabel Sharman Crawford Scholarship.—Grace Nicolle, Lond. Sch. of Med. for Women.

London Hospital Medical College.—Price Scholarship in Science.—F. W. Ta'Bois, E. Lond. Coll. Science Scholarship.—H. Evans, E. Lond. Coll.

Royal College of Physicians of London.—The Mitchell Lecture will be delivered by Dr. F. Parkes Weber on Tuesday, Nov. 1st, at 5 p.m., on the Relations of Tuberculosis to General Conditions of the Body and Diseases other than Tuberculosis. On Nov. 3rd, at 5 p.m., Dr. Michael Grabham will give the Bradshaw Lecture on Sub-Tropical Esculents. Dr. R. O. Moon will give the Fitz-Patrick Lectures on Nov. 8th and 10th, at 5 p.m., his subject being Hippocrates in Relation to the Philosophy of his Time.

West London Medico-Chirurgical Society.—The opening meeting of the fortieth session of this society will take place at the West London Hospital on Friday, Oct. 7th, at 8.30 p.m., when Sir G. Lenthal Cheatle will give his presidential address on a Study of Breast Cancer in Relation to the Cancer Problem.

London (R.F.H.) School of Medicine for Women.—The introductory address on the occasion of the opening of the winter session on Oct. 3rd will be given at 3 p.m. by Dr. Louisa Martindale on the Woman Doctor and her Future.

St. Mary's Hospital: Past and Present Students' Dinner.—Dr. E. G. Graham Little will preside at this dinner, which will be held at the Connaught Rooms, Great Queen-street, at 7 for 7.30 p.m., on Monday, Oct. 3rd. Applications for tickets (12*s.* 6*d.*, exclusive of wine) should be addressed to Dr. A. Hope Gosse, the Hon. Sec., 15, Queen Anne-street, London, W. 1.

Middlesex Hospital Medical School.—The opening of the winter session will be held at the Scala Theatre on Tuesday, Oct. 4th, at 3 p.m. Mr. Gordon Taylor will deliver the introductory address and Sir John Bland-Sutton will distribute the prizes. The annual dinner will be held on the same date at 7.30 p.m. at the Trocadero Restaurant, Piccadilly Circus, London, W.

St. Thomas's Hospital: Old Students' Dinner. Dr. H. W. G. Mackenzie will take the chair at this dinner, which will be held at the Wharncliffe Rooms, Hotel Great Central, London, N.W., on Friday, Oct. 28th, at 7 for 7.30 p.m. The price of the dinner, inclusive, is 17*s.* 6*d.*, to be paid at the Wharncliffe Rooms. Applications for seats should be sent as soon as possible to the Hon. Secretaries, Dr. H. B. Russell and Mr. L. N. Reece, at St. Thomas's Hospital, S.E. 1.

Charing Cross Hospital Medical School.—The annual distribution of prizes will take place in the out-patients' hall of the hospital on Wednesday, Oct. 5th, at 3.30 p.m. The distributor will be Sir Frederick Mott, F.R.S., and the chairman Sir Herbert Waterhouse.

The annual dinner of past and present students will be held on the evening of the same day at the Adelaide Gallery, Gatti's Restaurant at 7 for 7.30 p.m. The chairman will be Sir James Galloway, and the guest of the evening Sir Frederick Mott. Tickets 12*s.* 6*d.* each may be obtained from the Dean or may be paid for at the door.

Popular Lectures on Psychology.—Among the courses of public lectures to be delivered at King's College, Strand, W.C., during the forthcoming Michaelmas term is one on Psychology and Psycho-Therapy by Dr. William Brown, Wilde Reader on Mental Philosophy at the University of Oxford. The course will consist of ten lectures, the first of which will be given on Oct. 18th at 5.30 p.m., and the remainder on successive Tuesdays.

them to hold the view that an inquiry into the administration of sickness benefit by approved societies is much more necessary. The general impression received is that the approved society has not the least concern with the sickness or circumstances of the insured person, that its aim and object is to pay out as little sickness benefit as possible, and that not sooner than can be avoided. During the war there were difficulties, and within the last year some societies have been administering sick benefit humanely and intelligently. Yet there is much room for improvement, especially on the question of certification, which is a fruitful source of irritation between patient and doctor. Although the regulations allow a certificate to cover from Sunday to Sunday, there is still much worrying for certificates on special days and times, and withholding of benefit if a certificate is not forthcoming.

In a case of death it not infrequently happens that a "final" certificate, which means capacity for work, is demanded to cover the period between the death and the last intermediate certificate, even although the agent has seen the death certificate and "viewed" the body. It would be tedious to enlarge on the vagaries and irritations of certification. It is recognised that accurate certification is necessary to cover incapacity, but it has to be approached from a different aspect than that adopted by approved societies before smooth or efficient working can be established. A survey of the inquiries on questions arising out of certification demonstrates how vexatious to the doctor certification can become. As an example, a doctor giving a good service certifies an insured person, after careful examination, as suffering from "abdominal pains." The patient is kept under observation for a week, and, as no further developments occurred, certifies her fit for work, using "abdominal pains" again. The approved society demands an inquiry for incomplete certification. The health visitor, another asset of the approved society, is of questionable value, and undoubtedly a frequent source of friction. When bandages are removed, pulses felt, tongues inspected, and when the charlady, recovering from influenza, is reported for doing a little charing for herself, it need cause no surprise that health visits are not always appreciated as they might be. The visitors are viewed as detectives watching the doctor and insured person. At one time the approved societies employed referees to "coax the lazy ones" of sick benefit at half a guinea or a guinea at a time, but this duty is now undertaken by the regional medical officers of the Ministry, at a cost to the approved society of *10d.* a time. The Ministry has a reputation for business instinct, and as the cases are mostly chronic it is difficult to see how national health may be advanced by estimating their earning capacity to a decimal point. Yet many of these poor people are harried every three months or oftener at *10d.* a time because the panel doctor is not supposed to be able honestly to judge their fitness for work.

It may be wondered how it happens that so little has been heard of complaints against the administration of sick benefit. This is easily explained. The only means by which an insured person can obtain redress is to apply to the disputes committee of his approved society, with a deposit of £1, which is forfeited if his complaint fails. It is when we arrive at the insurance committee, which administers medical benefit, that we get a grip of the predominating factor in the dissatisfaction. The London Insurance Committee has been from the start hostile to the panel doctor, has appeared to encourage complaints against him, and to conduct its inquiries with bias. Insured persons are not supplied with title to medical benefit for months or even years, and their title to benefit is constantly being questioned. Their names are removed from doctors' lists for this reason, although at the time their title may be such as allows them to receive sickness benefit—a position which gives occasion for unpleasantness between doctor and patient. But there is much worse than this. It will be agreed that the doctor has a right to receive information as to the extent and direction of his responsibility. Article 18 of the Medical Benefit Regulations, 1920, provides that practitioners shall be supplied by the insurance committee with a correct list of insured persons whom he has accepted. It further provides that this list shall be kept correct to date, and it is the duty of an insurance committee to supply the doctor with the necessary information. This duty has been neglected by the London Insurance Committee, and there is reason to believe that London is not alone in this respect. It would be difficult to contemplate medical service being rendered contentedly and efficiently under such circumstances. The issue of Forms Medical Record, hurried as it was, has revealed a disturbing state of affairs, calling for immediate inquiry; the errors in individual lists have been shown to be anything from 12 to 33 per cent. and of a varied character.

Having considered the effect and operation of outside influences it is possible to examine the evidence regarding the character of the medical service. During 1919, a year above the average, there were 66 inquiries. Of these 42 were substantiated. This means that one in every 25,000 insured persons felt he had a grievance, or one complaint in about 100,000 attendances, and, as several of these complaints were against the same practitioner, it would mean that 66 doctors at most out of 1500 on the panel had given cause, real or imaginary, for inquiry. Inasmuch as the insured person understands that it is his right to lodge complaints, however trivial, the comparative smallness of the number of complaints becomes very real. Highly placed approved society officials have alleged that malingering is encouraged by the medical profession. These statements have to be put against the fact that surpluses of many millions have been placed to the credit of a majority of the societies. When we consider how carefully the actuaries estimated the cost of sickness benefit in 1912, it is surely just to suggest that part at any rate of the huge surplus is due to the efficiency of the medical service; otherwise approved societies have been depriving members of their due.

No one contends that the medical service of the general practitioner on the panel is perfect, but it can with confidence be asserted that an honest inquiry would show the "panel doctor" to be as efficient as any other section of the profession, to have as strong a sense of duty, and to be as meticulously careful of his performance of that duty. All he asks is a fair chance.

I am, Sir, yours faithfully,

Champion Park, S.E., Sept. 19th, 1921. H. G. COWIE.

SOME TOXÆMIAS OF PREGNANCY.

To the Editor of THE LANCET.

SIR,—In a leading article with this title in your last issue the following occurs: "The marked accumulation of urea and other nitrogenous waste products, so frequently seen in acute and certain types of chronic nephritis, is absent in the toxæmias of pregnancy. The non-protein nitrogen and urea of the blood are frequently within normal limits." And this difference, the article continues, "serves to differentiate the true eclamptic from cases of uræmia due to chronic interstitial nephritis complicating pregnancy."

I venture to ask how is it possible that "a definite nitrogenous retention" in the blood should be absent in a disease in which extensive necrosis and degeneration of liver cells and of kidney cells are the characteristic features? Does not the liver safeguard the body from the inroad of poisonous non-protein nitrogenous bodies? Is it not one of this organ's functions to transform these amino- (and allied) bodies into the innocuous urea? If, then, the liver is the seat of such a profound degeneration as is the case in the pre-eclamptic toxæmia, how can the general blood fail to become surcharged with these

Elizabeth Garrett Anderson Hospital, Euston-road.—Female Asst. S.
Glasgow Asylum Service.—Asst. M.O. and Pathologist. £275.

Wolverhampton and Staffordshire General Hospital.—Res. M.O. £200.

The Chief Inspector of Factories, Home Office, S.W., announces the following vacant appointment:—Newton Stewart (Wigtown).

Births, Marriages, and Deaths.

BIRTHS.

GRACE.—On Sept. 14th, at Gloucester-crescent, Regent's Park, the wife of W. H. Grace, M.B., M.R.C.P. Lond., of a son.

MORRIS.—On Sept. 18th, the wife of Lionel F. Morris, L.D.S. R.C.S. Eng., of West Moor, Bournemouth, of a daughter.

REICHWALD.—On Sept. 16th, at Timber Hill, Ashtead, the wife of M. B. Reichwald, of a son.

MARRIAGES.

BAMPTON—PURSLOW.—On the 10th inst., at St. Simon's Church, Southsea, by the Rev. N. E. Ashenden, M.A., Horace Edgar Bampton, L.D.S. R.C.S. Eng., of Four Oaks, to Alice Maud Mary, daughter of Dr. and Mrs. Purslow, of Broad-street, Birmingham, and Southsea.

BROWNE—CARROLL.—On Sept. 15th, at Minehead, Lieut.-Colonel C. G. Browne, C.M.G., D.S.O., R.A.M.C., to Florence (Pat), eldest daughter of Brigadier-General J. W. Carroll, C.M.G., D.S.O. (late Norfolk Regiment.) and Mrs. Carroll, of Boldon, Minehead, Somerset.

FOULKES—VAUGHAN.—On Sept. 17th, at Emmanuel Church, Camberwell, Richard Kenrick Foulkes, M.B., to Mary Gwendolen, only daughter of the Rev. F. D. and Mrs. Vaughan, of Emmanuel Vicarage, Camberwell.

DEATHS.

BYAM.—On Sept. 12th, at Worthing, from peritonitis, Samuel Henry Byam, L.R.C.P. Lond., M.R.C.S. Eng., of Chester-square, London, S.W., aged 73 years.

FAULDER.—On Sept. 11th, at Glendaruel, Argyllshire, Julia, the beloved wife of Major T. J. Faulder, F.R.C.S., R.A.M.C. (T.A.) and elder daughter of W. Harrison Cripps, Esq., F.R.C.S., of Glendaruel.

MCCREERY.—On Sept. 10th, at Colaba War Hospital, Bombay, Major A. T. J. McCreery, M.C., R.A.M.C., eldest son of the late Colonel B. T. McCreery, R.A.M.C.

ROBERTS.—On Sept. 5th, in Madras, Lieut.-Colonel Edmund Arthur Roberts, D.S.O., I.M.S.

WILLIAMS JONES.—On Sept. 16th, at Prestatyn, North Wales, John Williams Jones, of 2, Albert-road, Whalley Range, Manchester, L.R.C.P. & S. Edin. and L.M. Glasg., in his 68th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PRESENT POSITION OF PSYCHOTHERAPY.

BY MILLAIS CULPIN, M.D. LOND., F.R.C.S. ENG.,
LECTURER ON PSYCHONEUROSES, LONDON HOSPITAL.

AN increased interest in the psychological aspect of medicine is one of the unexpected results of the war. Soon after the outbreak of hostilities officers and men were invalided home in fairly large numbers under the diagnosis of "concussion" or "shell-shock," and presented symptoms which were ascribed to these physical causes. Newspaper stories appeared of marvellous recoveries from mutism, blindness, or paralysis in returned soldiers, and it was finally recognised that the words "concussion" and "shell-shock" (the latter had by then been made an official term) were by no means synonymous, but indicated two groups with causations diametrically opposite, one being physical and the other mental. The physical symptoms of the mental condition were recognised as identical with those described in civil life under the name of hysteria, and, in fact, Hector Gavin[1] had described as early as 1843 practically all the physical disabilities seen in these cases of shell-shock. The assumption that shell-shock had a gross anatomical basis recalls the half-forgotten controversy concerning "railway spine"—a condition regarded as due to gross organic changes till the efforts of H. W. Page and the late Furneaux Jordan established its emotional origin. One regrets that the work of these surgeons was overlooked in the attempt to establish an anatomical pathology of shell-shock; Page's book, "Railway Injuries,"[2] needs only the addition of a chapter on modern psychological theories to make it a complete picture of the war neuroses. The centre of interest gradually shifted from the bodily symptoms known to be dependent upon mental disturbances, and attention was directed more to the mental disturbances themselves. This change coincided with a change in the nature of the cases which, as time passed, presented less of the hysterical symptoms and came more into line with the compulsion and obsessional neuroses, anxiety states, and psychasthenias of civil life. These latter conditions are generally found classified as "neurasthenia"—a term which now has little value for purposes of definition, though there are a few cases to which it may properly be applied.

Mental and Physical Causes.

The physical aspect of the subject is concerned with:—

(*a*) True concussion, often followed by symptoms scarcely to be distinguished from those produced by strong emotion. Careful psychological investigation of individual cases is necessary before the physical and mental factors can be separated, but it is to be noted that the claim of men suffering from shell-shock to have been unconscious for a varying period after the shock rarely rests upon a true insensibility, but upon a loss of memory which can often be restored by psychological means (hypnosis, &c.).

(*b*) The effect of vibration upon the molecular structure of the brain. Carver and Dinsley[3] produce evidence to show that the vibrations produced by a certain sequence of explosions cause psychical effects, which suggests that, just as explosives may be discharged by other explosions at a distance, so the cells of the central nervous system may react to particular vibrations.

(*c*) Toxins, whether their action is direct, upon the nerve centres, or indirect, by lowering the sense of well-being.

(*d*) The functions of the endocrine glands, which are closely associated with emotion. Here is to be sought the explanation of those cases diagnosed in the army as disordered action of the heart, or effort syndrome, which are now claimed as their own by both cardiologists and neurologists.[4] Nervous symptoms commonly occur with the cardiac disability, and in addition there are found excessive sweating, cyanosis of the hands, fine tremors, easy induction of nervous and muscular fatigue, and other symptoms dependent upon interference with the sympathetic nervous system and the ductless glands.

The conception of a physical causation for hysteria had long been abandoned, though physical means are still commonly used in its treatment. With regard to other nervous conditions, opinion was less definite; the cause of of that day. Further than this, Nierenstein's researches appear to invalidate Prof. Halliburton's statement that the cells lining the choroid plexus constitute an absolute barrier preventing arsenic from entering the cerebro-spinal fluid.

It might not be out of place to draw attention to the past literature on this subject, more especially to the period when inquiry into every form of therapeutics in connexion with trypanosomiasis was at the height of its activity. Consequent on important work on sera by Schilling (1905), Klein and Möllers (1906), Mesnil and Brimont[3] studied this question and an extract from a review of their paper is as follows:—

> "Action in vitro of the serums on the trypanosomes.—The trypanosomes of the last experiment after half-an-hour's contact with active serums showed a vitality as great as that of the control trypanosomes. It was thought possible that the effect of the serums might be evident later. Trypanosomes were therefore put in contact with active serums, inactive serums, and in the citrated water with which they were diluted, in each case at 18° and 37°. In a great number of trials no microbicidal action was observed; the active serums behaved like the inactive; in both the trypanosomes kept their vitality longer than those in the citrated water; it was kept longer still when heated serums were used. The protective power of the serums is therefore not due to trypanolytic action. The two properties, when they exist together, are independent. Nor did the addition of serum from the mouse to supply complement bring about trypanolysis. The agglutinating power of the serums was very inconstant, and never well marked; it exists also in some fresh serums; agglutinative power has no sort of relation to protective power. Anti-lewisi serum is the only one for which agglutination is characteristic, and here Laveran and Mesnil have shown the independence of agglutinating and preventive power."

Following on the work of Laveran and Mesnil, Goebel,[4] among other conclusions, found that—

> (1) Human serum digested at 37° with trypanosomes does not lose its preventive and curative properties. The parasites which have remained in it preserve their infectivity completely.
>
> (2) "Human serum does not show any opsonic or cytotropic property as regards trypanosomes. In any case it does not change the parasites so as to make them an easy prey for leucocytes."

Research undertaken by Levaditi and Mutermilch is described[5] as follows:—

> "The authors mixed trypanosomes from the blood of a mouse with serum from guinea-pigs killed in the course of a third relapse, and added complement. At 38° the degree of trypanolysis was proportional to the quantity of trypanocidal serum added. With certain quantities microscopical examination showed that all the parasites were immobile and had become round and transparent. It was thought that sterilisation was complete, but when some of these mixtures were injected into mice the animals became infected with trypanosomes and died. The authors suggested that those parasites which had succeeded in multiplying in the blood of the mice had become resistant to the antibodies with which they were in contact in the test-tube: experiment showed that it was so."

From the above it would appear that the blood serum of animals, whether suffering from trypanosomiasis or not, contains little if any trypanolysin, and that trypanosomes kept for some time in contact with such sera do not lose their infectivity; in fact, according to later researches, they become in certain cases resistant. The conclusions that Dr. Marshall arrives at and the hopes expressed that "in man prophylaxis and immunisation against trypanosome infection might be so attained"—i.e., by the use of animal serums—are certainly not supported by the researches of many eminent workers, and are also perhaps not without danger.

Regarding complement-fixation, Beck's experiments, like those of previous workers, led to no practical conclusions. He doubts whether complement-fixation will ever become of use in the diagnosis of human trypanosomiasis."[6] As Dr. Marshall appears to have had such promising results, we trust that he will be given ample opportunity for continuing his work, and if he can bring it to a satisfactory termination he will have achieved remarkable success. I am sure we all wish him the best of luck.

I am, Sir, yours faithfully,

Dar-es-Salaam, July 14th, 1921. J. O. SHIRCORE.

*** Dr. Shircore's letter makes it clear that intrathecal serum treatment for trypanosomiasis was tried even earlier than was suggested in an annotation on Sept. 10th, p. 573.—ED. L.

NATIONAL PROVIDENT SCHEME.

To the Editor of THE LANCET.

SIR,—In the National Provident Scheme for Hospital and Additional Medical Services in London, as detailed in your current issue, is there intended to be any differentiation between earned income and income derived from capital? If there is no such differentiation, what is to prevent an individual, with an income of £250 derived from invested capital of £5000, from becoming a member at an annual subscription of £1?—I am, Sir, yours faithfully,

C. HAMILTON WHITEFORD.

Plymouth, Sept. 17th, 1921.

The Services.

WOMEN'S MEDICAL SERVICE FOR INDIA.

CERTAIN progressive steps are recorded in the annual report for 1920 of the Women's Medical Service for India (W.M.S.I.), incorporated in the report of the National Association for Supplying Female Medical Aid to the Women of India.[1] A deputation from 16 members of the Service, received by its President Lady Chelmsford in February, 1920, urged, in the interests of the Service, especially with regard to pay and status, that it should be taken over by the Government of India. Lady Chelmsford replied that though the proposal for a Government service was not at present practicable, the question of increased pay[2] was already under consideration and the desire for a more definite status would be met if possible. The Viceroy was officially approached by the Council in the following September with a view to obtaining for officers of the W.M.S.I. a place in the Warrant of Precedence in India, and meanwhile local governments were asked to accord to officers of the W.M.S.I. gazetted rank and to issue orders that they be treated on all occasions with the consideration paid to gazetted officers. This last request shows that the lack of official recognition in a country where precedence counts for so much has been felt, and for the dignity of the service it is to be hoped that the response of the Viceroy has been favourable. The United Provinces, alone of the Provinces, had replied when the report was issued and their answer was immediately to bestow gazetted rank on all officers of the W.M.S.I. Meanwhile, the service has altered its internal nomenclature more in accordance with the traditions of a government service, doubtless in hopeful anticipation of a change in the official attitude. Dr. M. I. Balfour, one of the joint secretaries of the service, is now its chief medical officer. The assistants to the surgeons-general or inspectors-general are now to be known as senior medical officers, and those engaged in hospital duties are graded as executive medical officers of the first, second, third, and fourth grades. The bestowal of certain executive powers on the chief medical officer is under consideration.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs.—G. D. Walsh to *Defiance*; C. H. Dawe to *President*, addl., for four months' hospital course; and F. H. Holt to *Renown*. Surg. Lieut.-Comdrs. C. F. O. Sankey to *Harebell*; and W. P. Beattie to *Cerce*. Surg. Lieut. J. F. Haynes to *Woodlark*.

[2] The scale of pay recorded in our Students' Number (August 27th) is the recently revised scale.

Present Conditions.

This survey of the trend of opinion indicates that at the outbreak of war we were little prepared to deal on a large scale with casualties that needed treatment by the methods discussed above; the large number of neurological cases occurring in the army called for action, and neurological centres were established both at home and in the war areas. But functional nervous disorders had hitherto been neglected in the training of the medical student, and clinics for their treatment were practically unknown. The need for training medical men was faced, and during the war centres were established at Maghull and Seale Hayne, to which were sent R.A.M.C. officers and others for a course of training in the subject. Even now the supply of practitioners able to understand and treat cases among pensioners is so insufficient that the Ministry of Pensions offers a course of training at Tooting under the direction of Dr. R. G. Rows, formerly in charge of the Maghull centre. The care or treatment of the insane soldier was separated from that of the psychoneurotic, though difficulties of diagnosis caused occasional errors. The strangeness and severity of some psychoneurotic conditions led to diagnoses of insanity which were ultimately revised, and, on the other hand, a small proportion of the inmates of neurological hospitals became certifiable. The authorities met this difficulty when they established hospitals under expert psychiatrists, where soldiers were kept under observation for a period of not less than nine months before being certified as insane. The needs of pensioners are now being met by the establishment of out-patient clinics, hospitals, and training centres all over the country. The Maudsley Hospital, the fate of which is just now in the balance, is an example of institutions where "border-line" cases are taken for investigation. It must be admitted that these efforts are hampered by the facts that pensioners need much urging before they will accept treatment, and that in mental cases neither the patients nor their friends are always the best judges as to what treatment is necessary. The "neurasthenic" pensioner is a special problem,[7] for his neurotic symptoms serve as a flight from hard reality, and in present economic conditions he is at a considerable disadvantage in the labour market, so that his adjustment to reality often becomes impossible. This condition is not to be taken as indicating a deliberate malingering, or retention of symptoms for a conscious end; the influence of financial and domestic worry cannot be denied in cases occurring in private practice where no question of pension arises.

The experience gained during the war, and especially the recognition that many—probably at least half—of the war patients had suffered from nervous manifestations before enlistment, helped to draw attention to the needs of the civil population. The sufferer from a bodily hysterical disability had hitherto been regarded with a certain degree of contumely, as being responsible for a condition which he or she ought to overcome by a little common-sense. Presumed organic disorders cured by pious pilgrimages, bone-setters, Christian Science and similar means, were explained as hysterical, and our professional responsibility ceased with the making of the diagnosis. But if hysteria is curable it should be our duty to cure it, and if others succeed when we have failed we must be honest enough to confess our failure. The war has taught that even the hysteric may desire to be cured, and the sufferers from other psychoneuroses bear them in silence only because they have come to regard their condition as beyond our help. Hitherto the student has felt that the subject is unimportant, that treatment is directed by no intelligible principles, and that the sufferers themselves are mere nuisances and may properly be left to their troubles; but the attention given to functional nervous disorders during and after the war, and the diffusion of knowledge concerning them, should make itself felt in medical education, especially when the ever-widening field of psycho-therapy is recognised. That such diverse conditions as asthma, writer's cramp, and stammering should be placed among the functional nervous disorders now found amenable to treatment by mental exploration is an indication of the practical value of that treatment.

The study and treatment of psycho-neuroses and of cases on the border-line of insanity are inseparable; neglect of one is associated with neglect of the other, and in the past our students have derived their knowledge of psychiatry from a few visits to an asylum where they saw advanced certified cases of mental disease. In practice medical men are faced with early or doubtful cases in which, under present conditions, little or nothing can be done until the patient is certifiably insane, unless his position is such that he can afford the luxury of a private institution for an indefinite period. The city of Birmingham has shown a good example by the establishment of a "nerve hospital," containing 35 beds, and situated in grounds of several acres. Here are admitted cases of functional nervous disorders requiring in-patient treatment, and amongst these will come the "border-line" sufferers who would otherwise remain untreated until they became fit for an asylum. An out-patient department is worked in conjunction, and the treatment is along the lines indicated by modern psychology. Special out-patient clinics have been established at some of our large hospitals, but there is a general lack of such provision as Birmingham provides for treating the potentially insane when he is still accessible to treatment.

A description of clinics and hospitals on the Continent, where non-certifiable cases are received without the stigma attached to asylum treatment, is given in the work on shell-shock by Elliot Smith and T. H. Pear.[8] This book, in spite of its title, is a plea for the early treatment of the uncertifiable cases of civil life, and in it emphasis is laid upon the observation that the hereditary nature of mental disorders is probably over-rated; just as tuberculosis is now known to be often conveyed from parent to offspring by infection and not by heredity, so the evil home influence inseparable from the presence of neurotic or drunken parents is bound to produce effects upon the mental stability of their children quite apart from or in addition to the effects of hereditary predisposition. H. Crichton Miller[9] shows this in the study of 28 army cases, where he traced failure of mental adaptation in adult life to the influence of a drunken or cruel father with a resulting fixation upon the mother; he admits the hereditary element, but the developmental flaw is far more apparent. The psychological investigation of juvenile delinquents offers a promising field with prospects of ameliorating or curing criminal tendencies. Sentimentality has no place in this question—if a child or young adult can be saved from a bad career only by a term of imprisonment then the imprisonment is justified; but such punishment obviously fails in many cases. Committal to a reformatory, or supervision by a court official or missionary, is an effort in the right direction, but more is needed. A child who repeatedly offends in a particular way, who derives no obvious benefit or pleasure from the offence, and on whom punishment has no deterrent effect, is urged by a motive hidden from the casual observer. The offenders are not carrying out conscious wishes, for they are urged by some impulse which they cannot resist or understand; they may even be keenly sensitive to their disgrace and long to be cured of the impulse. Kleptomania as a plea in defence has become a by-word, but there certainly are cases where the impulse to steal is psychologically on all fours with a psychoneurotic obsession, and, like it, is a fit matter for investigation and treatment.

William Healy, Director of the Psychopathic Institute of the Juvenile Court, Chicago, has shown[10] the application of the theory of the unconscious to these cases. Stealing, vagrancy, truancy, and other examples of misbehaviour were investigated by him and his colleagues, and by the use of methods which he admits were often superficial it was found that of 2000 cases over 7 per cent. presented examples of mental conflict, generally sexual in origin, as a main cause of the delinquency. Let us bear in mind that the trouble arose from a struggle against something which the child believed was evil—that the evil thought, thrust into the unconscious, yet possessed such dynamic energy that it manifested itself in the pathological impulse to offend. In these cases the correct treatment is by mental exploration; the use of restraint or punishment only increases the conflict and creates an anti-social grievance in the mind of the sufferer. In our country we have very little experience of this particular application of psycho-therapy; but it is plain that the elucidation of the mental processes concerned cannot be undertaken by those untrained in methods of mental exploration, which is something more than mere questioning of the patient.

General Survey of Opinion.

Healy shows how the new methods are finding application in America. In Austria and Germany the adherents of Freud are very active, and meet with great opposition; an energetic controversy concerning the mental or physical cause of the war neuroses seems to have ended in a victory for the advocates of the former. A centre of clinical research and literary activity is the Psychiatric Clinic of the University of Zurich, where Jung and his colleagues, departing from the absolute sexual theory of Freud, have built up a psycho-analytical philosophy based upon unconscious strivings not necessarily of a sexual nature. The principles of Jung have a fair number of adherents in this country. In France the influence of Babinski and Bernheim is still powerful; suggestion is regarded as the cause

NATIONAL HOSPITAL FOR DISEASES OF THE HEART: POST-GRADUATE COURSE.—A special course of ten systematic lectures will begin on Monday, Oct. 10th, at 5.30 P.M., when Dr. J. Parkinson will lecture on Aortic Disease. Subsequent lectures, to be given by Sir S. Russell-Wells, Dr. P. Hamill, Dr. F. W. Price, Dr. J. S. Goodall, Dr. R. O. Moon, and Dr. B. T. Parsons-Smith, will be announced in our Medical Diary. Clinical demonstrations are given, and the clinical practice of the hospital is open to post-graduate members of the course. A fee of £2 2*s.* per month, or £5 5*s.* for three months, is charged. Appointments as clinical assistants are also open to members of the course. All inquiries should be addressed to the Dean, Dr. P. Hamill, and cheques made payable to the Secretary of the Hospital at Westmoreland-street, W. 1.

SOME PROBLEMS OF MODERN BIOLOGY.—A course of 24 lectures under this general title will be given at Gresham College, Basinghall-street, London, E.C., on Mondays, at 6 P.M., beginning Oct. 3rd, by Mr. William B. Brierley, D.Sc. The aim of the lectures, which are being given as a university extension course, is to make a survey in the light of recent experimental research of some of the main problems and tendencies in biology and to attempt to build up a coherent system. The lectures are divided into four groups under the headings: (*a*) Problems of Life, Growth, and Death; (*b*) Problems of Sex and Inheritance; (*c*) Problems of Interpretation; and (*d*) Problems of Practice. The fee for the session of 24 lectures is 17*s.* 6*d.*, or 10*s.* for the term of 12. Admission to the first lecture on the Origin of Life is free and to each subsequent single lecture 1*s.* 6*d.* Further particulars as to this and other university extension courses may be obtained from Mr. J. Lea, University Extension Registrar, University of London, S. Kensington.

ROYAL INSTITUTE OF PUBLIC HEALTH.—A course of eight lectures and discussions on Problems of Public Health in Relation to Industrial Hygiene will be delivered in the lecture theatre of the Institute, 37, Russell-square, London, W.C., on Wednesdays, at 4 P.M., starting on Oct. 19th. The first lecture will be delivered by Sir Thomas Oliver on Problems of Industrial Hygiene in Relation to Public Health, Lord Askwith presiding. Subsequent lectures, which will be announced in our medical diary, will be given by Dr. R. M. Wilson, Dr. H. M. Vernon, Prof. Louise McIlroy, Prof. S. Lyle Cummins, Dr. R. Prosser White, Prof. Edgar L. Collis, and Sir Kenneth Goadby. A discussion will follow each lecture. Medical officers of health, medical practitioners, sanitarians, medical students, and all men and women engaged in any form of public health service or interested in medico-sociological problems are invited to attend. Further particulars may be obtained on application to the Secretary, The Royal Institute of Public Health, 37, Russell-square, London, W.C. 1.

BETHLEM ROYAL HOSPITAL.—A course of lectures and practical instruction for the Diploma in Psychological Medicine granted by the various universities has been arranged to commence on Monday, Oct. 10th. The course is divided into two parts. Part A comprises the anatomy, histology, and physiology of the nervous system, together with psychology (general, experimental, and of dreams). Part B comprises neurology, psychological medicine, and mental deficiency. Lectures will be delivered by Sir Maurice Craig, Drs. S. A. Kinnier Wilson, C. Worster-Drought, F. C. E. Danvers-Atkinson, Clement Lovell, William Brown, W. H. Rivers Rivers, E. D. Macnamara, W. H. B. Stoddart, R. Hunter Steen, J. G. Porter Phillips, Thomas Beaton, H. E. Wingfield, and A. R. Tredgold. The course will take place according to a time-table which may be obtained on application to the Physician Superintendent, Bethlem Hospital, S.E. 1. Fee for the full course £15 15*s.*; for either part separately, £10 10*s.*

NORFOLK AND NORWICH HOSPITAL.—The last quarterly report of this hospital forms a welcome contrast to the almost universal depression in the financial state of our voluntary hospitals. The board of governors reports that the increased financial support referred to in their last report has been continued, and that the expenditure for the first six months of this year has been covered by the income received in that time. This is a gratifying improvement on the condition of affairs prevailing last year, when the expenditure exceeded the income by £250 a week, as a result of which it was found necessary to close one of the wards. This improvement in the finances of the hospital is due, in the first place, to the result of the entertainments organised throughout the county on behalf of the hospital, which brought in the substantial sum of £6000 in six months; and secondly, to the growth of the contributory scheme in connexion with the Sunday and Saturday Fund, from which the institution received £3200 as a first instalment for this year. It has been decided to reopen the ward which had been temporarily closed, but the board urges subscribers to continue their efforts, and reminds them that there is still an overdraft of £28,000 due to the bank. The quarterly report of the work done by the hospital shows that the in-patients numbered 711, against 833 in the corresponding quarter of 1920; the daily average of in-patients was 234, against 263 last year. This diminution in numbers was no doubt due to the closing of a large ward; but, on the other hand, the number of operations was 521, compared with 401 last year. The new cases treated in the out-patient department were 827, and the accidents and casualties 1820, these figures last year having been 506 and 1862.

LONDON TELEPHONE EXCHANGE TRANSFERS.—From Paddington 3385 to Langham 2530, F. W. Price. From Mayfair 3677 to Grosvenor 1408, W. E. Robinson.

AMERICAN UROLOGICAL ASSOCIATION.—At the last annual meeting held at Montreal, Canada, in June, this Association decided to discontinue publication of the yearly transactions. Papers which have heretofore appeared in the transactions will be published in the *Journal of Urology* (Williams and Wilkins, Baltimore), which is now the official organ of the Association.

FOREIGN DECORATIONS.—The King has granted permission to wear the undermentioned decorations, which have been conferred in recognition of valuable services rendered:—The Order of the Nile, Second Class (Egypt), to Dr. Owen William Richards, C.M.G., D.S.O., Director, School of Medicine, Cairo; the Order of the Excellent Crop, Sixth Class (China), to Dr. Norman Hay Bolton, Medical Officer, Shanghai-Nanking Railway.

DONATIONS AND BEQUESTS.—The late Miss Hannah Amelia Irving, of Bennett Park, Blackheath, has left by will £3000 to the London Hospital to endow three beds in the Cancer Ward; £2000 to the Middlesex Hospital to endow two beds in the Cancer Ward; £200 each to the Royal London Ophthalmic Hospital, Moorfields, St. Mark's Hospital for Fistula, City-road, the East London Hospital for Children, the Surgical Aid Society, and the Poplar Hospital; £100 each to the Nursing Sisters of St. John The Divine, Bow-lane, E., and the Miller General Hospital, Greenwich. The residue of the estate is to be divided between the Royal Hospital for Incurables, Putney, the British Home and Hospital for Incurables, Streatham, and two other beneficiaries.—Under the will of the late Mr. Frank Sammon Parsons, of Shipston-on-Stour, who left estate of the gross value of £21,337, with net personalty £21,282, the testator left £2000 upon trust to pay three incomes to certain benefactors, with remainder to the Moreton-in-the-Marsh Cottage Hospital.

Appointments

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Wednesday morning of each week, such information for gratuitous publication.*

DUNSCOMBE, N. D., B.A., B.Ch. Cantab., L.M.S.S.A. Lond., has been appointed Assistant Medical Officer, Royal Earlswood Institution, Redhill, Surrey.

MACGILLIVRAY, G., M.B., Ch.B. Aberd., Tuberculosis Officer for Fife.

PRINGLE, K. D., M.B., B.C. Cantab., Medical Officer of Health to the Brecknock Rural District Council.

STEVENS, B. C., M.D., M.S. Durh., F.R.C.S. Edin., D.P.H. Oxf., Medical Officer of Health for the County Borough and Port of Grimsby.

Vacancies.

For further information refer to the advertisement columns.

Aylesford, Kent, Preston Hall Treatment and Training Colony for Tubercular Ex-Service Men.—Sen. Asst. M.O. £300.

Belfast District Asylum.—Two Asst. M.O.'s. £300.

Benenden, Kent, National Sanatorium.—Asst. M.O. £250.

Birkenhead, County Borough of.—Asst. M.O. £650.

Clifton, York, North Riding Mental Hospital.—Sen. Asst. M.O. £400.

Derby, Derbyshire Royal Infirmary.—Ophth. H.S. £200.

crowding; but nevertheless there was a marked decrease in the sickness and death-rates of the prisoners. The ratios of admission to hospital (1222·2 per 1000), daily average sick (48·0), and the deaths (43·6) were all considerably lower than in 1918, when these ratios had been 1497·5, 71·9, and 63·4 respectively. These figures afford a most striking testimony to the skill and care of the officers in charge of these institutions and their staff. The mortality was high at Angul (158·9), Hazaribagh (127·6), and Balasore (126·2), dysentery being the chief reason for the excess in each case. For the province as a whole malarial fever caused most admissions (304·6 per 1000), but only 1·0 per 1000 were fatal. Dysentery caused 193·2 per 1000 admissions and 15·8 deaths; diarrhœa, 150·4 admissions and 3·3 deaths. For pneumonia the ratios were only 9·6 and 3·5, as compared with 21·0 and 4·9 in 1918. An interesting table (No. XVII.) gives details as to death-rates for convicts in 1919, according to length of sojourn in jail. For six months or less the ratio was 65·9 per 1000; from six months to a year, 44·4; from one to two years, 30·3; from two to three years, 21·4; from three to seven years, 25·7; and above seven years, 3·2.

THE SUICIDE-RATE AND NATIONAL PROSPERITY.

According to the August number of the *Statistical Bulletin* of the Metropolitan Life Insurance Co., there are indications that the downward trend in the suicide death-rate in the U.S.A. has received a check this year. During the first seven months of 1921, the rate from suicide among more than 13 million industrial policyholders was 7·3 per 100,000, which is an increase of 26 per cent. over the rate for the corresponding period of 1920. Other observers have noted the same facts in different fields. The National Committee for Mental Hygiene has called attention to the marked increase in the number of suicides, especially among ex-soldiers and others in the general population.

The American suicide-rates of the past ten years present some interesting characteristics. During the period 1911 to 1915, preceding the period of intense industrial activity during the war, only slight changes in the suicide death-rate are to be found. The second period, beginning with 1915, is that of the war years of great economic expansion and increased prosperity for the great body of the American people. Every year, both among the insured and the general population, recorded marked declines in the suicide-rate. In 1920 the rate among insured wage-earners was less than one-half what it had been in 1911. In the later months of 1920 a change seems to have set in which has continued throughout the first seven months of 1921. Month after month the suicide-rate is mounting over the corresponding figures for the months of 1920, and it is likely that the rate for the whole year will be higher than for the preceding one. It would be interesting to know to what degree the unemployment situation of the last year is responsible for the observed conditions as to suicide; suicide-rates may prove to be a sensitive index of the prevailing economic well-being of a people.

A STATE INSTITUTE OF HYGIENE IN PRAGUE.

A contract between the International Health Board of the Rockefeller Foundation and the Czecho-Slovak Ministry of Public Health and Physical Education has just been signed, by which a gift of 27,000,000 Cz. crowns has been accepted by the Czecho-Slovak Government for the erection of a State Institute of Hygiene, the Government agreeing to expend an additional 23,000,000 crowns for the project. Such an institution has been projected since the creation of the Ministry; it was conceived as a central public health laboratory, a school for health officers and sanitary personnel, and a research institution which would furnish a scientific background for the activities of the Ministry and save it from becoming a bureaucratic paper office.

When the budget for the Institute was made and was found to reach the sum of 50,000,000 Cz. crowns, it was felt that the strict economy made necessary by post-war conditions would not permit the realisation of this magnificent project. Later the Rockefeller Foundation's representatives, Colonel Frederic F. Russell and Prof. Selskar M. Gunn, came to Prague and the plan was presented to them and finally, with their recommendations, submitted to the International Health Board in New York. The land for the Institute has already been purchased and is located on both sides of a large hospital in Vinohrady, a suburb of Prague. It is one of the best and most modern hospitals of the capital and houses some of the teaching clinics of the Prague Medical Faculty. The close connexion between hospital and laboratories will be of advantage to both, giving excellent opportunities for research and teaching.

Plans for the Institute.

Plans have been made and agreed upon by both sides for a central large building and a smaller one. Stables, a power plant, a sewage purification plant, and houses for the personnel are included in the plans. The Institute will consist of several departments. The department for the production of small-pox vaccine and sera will be located in the small building which will also contain the department for Pasteur treatment for rabies. Patients requiring this treatment will be housed temporarily in the hospital, where two pavilions will be built for them. Later on those pavilions will be used for the contagious disease and gynæcological services of the hospital. The main building will have three stories: it will include a central diagnostic laboratory; the department for the control of foods, the department for the control of drugs, and finally, the department for research in hygiene. This last department will contain sections for school hygiene, an experimental station for water purification and sewage disposal, and departments for industrial hygiene and housing; the school for the training of health officers and sanitary personnel will be attached. The Institute will be entirely distinct from the medical faculty and will be administered by a board of directors made up in part from the prominent laboratory men of the country. Some of the future heads of departments have been already selected and sent to the United States at the expense of the Rockefeller Foundation for post-graduate study.

Medical Diary.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Special Intensive Course.

Monday, Sept. 26th.—4.30 p.m., Clinical Lecture:—Mr. C. J. Bond: Latent Infections (lantern).

Tuesday.—4.30 p.m., Dr. F. G. Crookshank: Colon Bacillus Infections.

Wednesday.—4.30 p.m., Mr. J. Berry: The Differential Diagnosis of Thyroid Swellings.

Thursday.—4.30 p.m., Colonel L. W. Harrison: The Routine Treatment of Syphilis and Tests of Cure in Gonorrhœa and Syphilis.

Friday.—4.30 p.m., Mr. H. W. Carson: Intussusception.

Saturday, 11 a.m., Dr. J. Macarthur (at the L.C.C. Mental Hospital, New Southgate, N.): Cases illustrating Emergencies in Mental Medicine.

Daily:—10.30 a.m. and 11.45 a.m., Demonstrations of Clinical and Laboratory Methods. 2 p.m., Demonstration of Groups of Clinical Cases. 3 p.m.: General Hospital Work. 4.30 p.m., Clinical Lecture (free to Medical Practitioners).

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Monday, Sept. 26th.—2 p.m., Dr. S. Pinchin: Medical Out-patients. Dr. Simson: Diseases of Women. Mr. MacDonald: Surgical Out-patients. 2.30 p.m., Mr. T. Gray: Visit to Surgical Wards.

Tuesday.—10 a.m., Mr. Steadman: Dental Department. 2 p.m., Dr. Burrell: Medical Out-patients. Mr. T. Gray: Surgical Out-patients. 2.30 p.m., Mr. Addison: Visit to Surgical Wards.

Wednesday.—10 a.m., Mr. MacDonald: Genito-Urinary Department. 2 p.m., Mr. Addison: Operations. Mr. Gibb: Eye Department. Mr. D. Armour: Visit to Surgical Wards.

Thursday.—2 p.m., Mr. D. Armour: Operations. Mr. B. Harman: Eye Department.

Friday.—10 a.m., Mr. D. Buxton: Dental Department. 2.30 p.m., Dr. Pritchard: Visit to Medical Wards.

Saturday.—10 a.m., Dr. Burnford: Visit to Medical Wards. 2 p.m., Dr. Owen: Medical Out-patients. Mr. Sinclair: Surgical Out-patients.

Daily: 10 a.m., Visit of Post-Graduates to Wards. 2 p.m., In-patient, Out-patient Clinics and Operations.

the symptoms vaguely described as neurasthenia was practically unexplained, though physical causes such as toxæmia were sometimes postulated. The view is still widely held that the physical condition is the primary cause when such troubles as constipation or enteroptosis are found associated with neurasthenia: similarly, in regard to the condition already alluded to as disordered action of the heart, it is often assumed that the nervous symptoms are secondary to the cardiac trouble. Those who approach nervous disorders from the psychological side do not ignore the action of toxins or exhaustion upon nerve centres—observation of febrile diseases would prevent such a mistake—but they find that mental causes underlie the diseases variously described as hysteria, anxiety states, compulsion or obsessional neuroses, psychasthenia, and neurasthenia. These are the conditions generally called nervous, and it is obvious that this use of the word, though sanctioned by custom, is incorrect: "nervous" diseases are mental. It is partly for this reason that "psychoneurosis" is often used in place of the older "neurosis." The link between bodily symptoms and mental states is probably to be found in the sympathetic nervous system and the ductless glands. Cannon[5] has shown how emotion affects the glandular secretions, and glandular secretions in turn have great influence upon bodily and mental functions. Although changes in the brain substance—in general paresis of the insane, for example—produce alteration in function, yet it does not follow that alterations in function must always be associated with demonstrable changes in structure. The fact that the symptoms of the psychoneuroses are amenable to psychotherapy does not lead us to expect to find their prime cause by the study of morbid anatomy.

With regard to insanity, the need for distinction between organic and mental causation is equally obvious. Different views concerning the pathology of that form known as dementia præcox illustrate a present conflict of opinion. To some authorities it is a disease of the brain, with added pathological changes in other structures—for example, the genital glands; on the other hand, it is regarded by some—e.g., by Jung—as a psycho-genetic disease with possibilities of treatment by psychological means, though the question is left open as to whether the mental cause may produce toxins that ultimately affect structure. The varieties of insanity which are believed to rest upon a psychological basis are manic-depressive insanity, dementia præcox, and paranoia. The importance of recognising their mental origin lies in the fact that in early stages the patients may be accessible to treatment. The inaccessibility to treatment shown by the insane, and their failure to recognise their infirmity, distinguish the psychoses from the psychoneuroses.

The Psychological Theory.

The outbreak of war came at a time when a new theory of the cause of mental disorders had attracted attention, and had been adopted by a few workers in this country. This theory was promulgated in 1895 by Freud, of Vienna, who found that hysterical symptoms were related to past incidents in the life of the patient which had been forgotten or repressed into a part of the mind which he calls the "unconscious." Being buried in the unconscious the memory does not lie dormant, but sends into the consciousness certain impulses which create the hysterical symptoms. By a process which he calls psycho-analysis the memories were brought to consciousness and the symptoms disappeared.

The theory soon became more elaborate; the buried memories proved to be connected with repressions concerning sex and those repressions went back to infancy, during which the sex instinct undergoes a course of evolution liable to arrest at any stage. Freud traces the sex instinct through a period of attachment to the self, then of attachment to the parent—usually the parent of opposite sex—till it finally reaches that stage of attachment or attraction to the opposite sex which we have hitherto regarded as the sum of normal sexuality. The instinct may be arrested at any of those stages, the memory of which is rarely or never within the consciousness of the adult, and the person concerned is at a disadvantage throughout life owing to this unconscious fixation upon a parent or upon a still more primitive sexual object. According to this theory, conflict and repression—one factor in the conflict being repressed by opposition of other interests or desires—produce the mental symptoms, and cure is sought by reviving memories excluded from consciousness, and by teaching the patient to face his troubles; when properly approached, the latter are often of little importance. The technique of this revival need not concern us, but making the patient work out the interpretation of his own dreams is an essential part of it.

This very brief summary of the "theory of the unconscious" at first sight bears little relation to war cases, but investigation of these has produced confirmation of at least a part of the theory. It had been freely assumed that a man who has passed through terrifying experiences should endeavour to forget them, and this assumption at first largely guided the treatment of war psychoneuroses. But it was soon found that any attempt to make a patient talk of his war experiences met at once with a definite refusal or some other form of resistance. When the man was persuaded to talk a difficulty in recall became obvious, and investigation by means of psychological technique revealed that even when the man had told all he knew there still remained in the majority of cases a loss of memory for strongly emotional incidents. Moreover, a total loss of memory for the war or even for the man's previous life was a well-known symptom in severe cases of shell-shock. Hence it followed that "forgetting," so far from being a necessary object of treatment, was already associated with the diseased state, and even formed part of it. When the memories were revived they were often proved to have found symbolic expression in the symptoms; stammers and tremors were obvious symbols of the terror attached to the repressed memory, and disappeared with its revival. Even the bizarre gasps, sniffs and grimaces occurring with the stammer represented definite repressions; disgust at horrible smells, the putting on of a gas mask, efforts to free the head when partly buried, have found symbolic representations in an individual stammerer, and difficulty with certain initials has referred to forgotten names with emotional significance. Hysterical gaits, dyspnœa, unreasonable fears and obsessions, nightmares, fits, and somnambulisms, as well as many unclassifiable symptoms, were similarly traced back to forgotten incidents and removed by their revival.[6]

These observations confirm the existence and influence of repression, and further consideration shows the repression to have resulted from conflict. Perhaps the conflict was between desire to avoid danger and discomfort, on the one side, and duty or sensibility to public opinion on the other. The desire became repressed into the unconscious but found expression in the symptom, the patient being unaware that the symptom was really a means of escape from the conflict. Conflict of this nature, in which a material end is sought unconsciously, is not so common as one might expect. More often the repugnant memory of the horrors of modern war was thrust down into the unconscious and later found expression in a psychoneurosis. Only a proportion of the cases showed an ætiology so completely related to war experience. Many soldiers broke down from mental strain before reaching the front line; there was a varying degree of resistance, so that some men succumbed at the thought of being called up, others broke down during training, at disembarkation in an enemy country, or at the first experience of shell-fire, and others only after years of strenuous fighting.

Resistance against breakdown obviously varied with the man's mental constitution, and an early breakdown was practically always correlated with a lowered resistance to the ordinary troubles of civil life, as shown by a history of previous nervous symptoms or illnesses. This was illustrated by a series of 397 neurological cases[6] which were divided into two groups—one of 150 men presenting a history of nervous predisposition or symptoms, and one of 217 men in whom investigation failed to find evidence of predisposition. The men of the first group had served abroad for an average of nine months, those of the second for an average of 10 months. It followed that the study of war cases could not be separated from the study of cases arising in civil life, and in these were found conflicts and repressions derived from causes apart from warfare, similar to those found in the simple war cases. This view of the processes concerned in the psychoneuroses may be regarded as definitely established, and it is accepted in the writings of William Brown, William McDougall, C. S. Myers, T. H. Pear, W. H. R. Rivers, R. G. Rows, G. Elliot Smith, and others.

At this point opinions diverge: psycho-analysis, whilst claiming that the predispositions revealed in so many cases are based upon infantile repressions, admit that patients are greatly benefited by revival of the more superficial unconscious material, but psycho-analysis in the proper sense of the word is so prolonged and difficult a task that one may safely say very few war cases have been fully studied by the psycho-analytical method. The names of individual workers quoted above probably represent as many degrees of acceptance of the theory of psycho-analysis, but the facts of repression and conflict must be regarded as established by war experience; this is a definite step forward in the understanding of mental diseases.

Persuasion, re-education, and suggestion still play their part in treatment, but it cannot be claimed that they are based upon such firm psycho-pathological grounds as are the various methods of mental exploration.

[5] Cannon, W. B.: Bodily Changes in Pain, &c. London: Appleton. 1915.

[6] Culpin, Millais: Psychoneuroses of War and Peace. Camb. Univ. Press. 1920.

X ray examination is invaluable in cases of acute right-sided pain, so often diagnosed incorrectly as appendicitis. At every period of duty at hospital when the house surgeon is new I am asked to see these cases of acute pain in the right iliac fossa as appendicitis, which they certainly are not; of the nature of some of them I am still uncertain. All with any surgical experience of the abdomen will recall cases in which the appendix was removed and a stone was later found in the ureter and had to be treated by operation or passed naturally, and many more in which the appendix was removed without relief for pain confined to the right iliac fossa. X ray investigation and careful examination of the urine will prevent the former mistake being made.

We must always be on the alert for tubal pregnancy and disease in women: these are frequent causes of unilateral pain, but tubal disease does not usually require immediate operation. One serious condition requiring immediate interference which may give rise to right-sided pain is perforation of a duodenal ulcer. In cases in which this is subacute and the fluid escapes slowly it may trickle down on the outer side of the ascending colon and give rise to right-sided symptoms; knowledge of this fact will prevent these cases from being overlooked.

SPECIAL INVESTIGATIONS IN CHRONIC CASES.

I will now pass to the type of case in which special investigations are so often necessary; in at least 90 per cent. of chronic cases we should have recourse to the pathological or X ray department at some time during the illness, either for diagnosis, prognosis, or both. Chronic abdominal diseases fall into two groups, those in which the diagnosis can be made by clinical methods—particularly careful history-taking—and those in which the symptoms are not clear and do not conform to those of any named disease. It is in the latter group that special methods of investigation are so helpful, although they should never be neglected as confirmatory evidence in the former.

I should like to give two examples from the latter group to illustrate my meaning. Both were women with left-sided pain, and in both the pain was diagnosed as renal in origin. The history in neither was typical; the pain—in its site and spread—did not have all the characteristics of renal pain; neither did it have the characteristics of pain due to the disease from which the patients were found eventually to be suffering—in one, an hour-glass stomach with a posterior ulcer eroding the pancreas, in the other malignant disease of the splenic flexure of the colon. By X ray investigation the correct diagnosis was made, which enabled me to carry out operative treatment successfully knowing beforehand the condition with which I had to deal.

VALUE OF X RAYS IN ABDOMINAL DIAGNOSIS.

In speaking of the value of X ray work in abdominal diagnosis one naturally starts with its earliest victory—that of revealing calculi in the urinary passages; this of itself is of the greatest value, not only in those elusive cases of right-sided pain, but also in many left-sided. Disease of the stomach, gall-bladder, and the appendix may all give rise to pain in the left iliac fossa and a suspicion of ureteric calculus raised, to be settled by this method of examination. This left-sided pain in chronic posterior gastric ulcer and in diseases of the gall-bladder is more common than is generally realised. It is unfortunate that so far X rays cannot reveal gall-stones for us with the same accuracy as they do stones in the urinary tract. The frequency, however, with which they are demonstrated is yearly increasing with greater knowledge and improved technique. While from time to time we are able to get positive results, the constitution and size of gall-stones differ so much that no reliance should be placed on negative reports; and we must always bear in mind that the causes of biliary colic are numerous and that a typical attack is not necessarily diagnostic of gall-stones. We have, therefore, to rely on our history, symptoms, and physical signs; we must make our diagnosis of biliary colic from history and symptoms, and occasionally are able, from symptoms and signs, to determine, definitely, its cause. If the diagnosis of biliary colic is to be correct, we must realise that the pain never starts in the gall-bladder region, but is epigastric or right round the waist as a band, in the back, and occasionally the left side.

The introduction of X ray investigation of the alimentary tract after an opaque meal has advanced our knowledge of abdominal anatomy and physiology, and, in certain cases, is a great aid in diagnosis. It has also the somewhat doubtful advantage that a shadow of the viscera can be depicted in a photograph that may be presented to the patient showing the dropped stomach or the dropped colon, whichever it happens to be the fashion to treat. The whole subject of visceroptosis is so complex and bound up with the well-being of the abdominal autonomic nervous system that it is very difficult to believe that any form of operation fixing ptoses of this description is likely to be of permanent good; in fact, more harm than good has been done in many of these cases. It is a treatment that should only be carried out as a last resort. I am not yet convinced that the mere fact that the stomach or cæcum is lower than is considered normal is any sign of disease.

X ray examination after an opaque meal may confirm the opinion formed that the case is one of visceroptosis, and, thus, if other disease can be excluded, in my opinion unlikely to be helped by operative treatment. We must guard against a too ready acceptance of this diagnosis. The symptoms of the condition are so various that it is difficult to be certain, and I always remind myself that the fact that a patient has visceroptosis does not shelter him from other more serious abdominal disease. Gall-stones, which it frequently mimics, are not infrequently found, and I have known carcinoma of the stomach overlooked in these patients, as it probably would not have been had an opaque meal been given.

ROUTINE X RAY EXAMINATION IN A GASTRIC CASE.

The opaque meal should be given six hours before the patient is to be examined. The first point to note is the rate of passage of the meal through the intestinal canal, much more important above than below; normally the whole of it should have left the stomach in five hours and the head of the meal should be half-way across the transverse colon. Any residue in the stomach is evidence of gastric stasis and denotes some organic lesion, the nature of which may be at once apparent by definite signs indicating the presence of carcinoma or ulcer. But these may exist without stasis; in this case a residue may sometimes be seen in the crater of an ulcer. The actual time taken for the material to leave the body is not important; there are such wide variations in individuals of normal health. It is important, however, that there should be no undue delay in the small intestine; such delay is, however, rare. The question of intestinal stasis and its treatment is so involved and of so controversial a character that I could not profitably discuss it briefly. I would, however, remark that I believe it is rarely necessary to operate, and that the failures of operative treatment far exceed the successes.

After these points have been noted, if the diagnosis is not clear the patient is again given a meal, and the tone, peristalsis, and position of the stomach first investigated. Filling defects indicative of growth, niches or accessory pockets, direct evidence of ulceration, may be noted, or the presence of a bilocular or hour-glass stomach. In the organic type the two pouches are rarely seen filled simultaneously, the fluid not infrequently being held in the upper for a considerable time before passing into the lower. The spasmodic type in which the stomach is ꙍ-shaped does not necessarily or usually denote an ulcer.

of hysteria, and the chief agent in its removal, though the methods of persuasion and explanation—perhaps owing their success to an element of suggestion—find their advocates. Janet remains an uncompromising opponent of the theories of Freud, though his own valuable work on dissociation as an explanation of certain mental phenomena was their direct precursor.

Taking a general view of recent development, we find a great increase of interest in the mental processes underlying certain disorders. The full theory of psycho-analysis, regarded by its supporters as an almost revolutionary conception of human thought-processes, is far from being generally accepted; but the investigation of the clinical material so abundant as one of the results of war has led to the establishment of many of its principles. The application of these principles to the study and treatment of psycho-neuroses, psychoses, and some varieties of criminality is already demonstrated to be of great practical utility.

PUBLIC HEALTH IN BIHAR AND ORISSA, 1919.

THE statistics of births and deaths in this province for the year 1919 are calculated on the census population of 1911—namely, 34,489,846. On this basis the birth ratio was 30·4 per 1000, as compared with 37·5 in 1918, and 39·5 in the quinquennium 1914–18; and the death ratio 40·0, as compared with 56·7 and 37·0. This low birth ratio was due to high prices of food, the epidemic of influenza, and the absence of a large number of both sexes recruited for the tea districts. The birth-rate varied from 22·6 in Manbhum district, and 22·8 in the Santal Parganas, to 35·7 in Gaya, and 36·2 in Palamau. In this district the birth-rate was exactly the same as the death-rate. In Patna the birth ratio (31·7) was 0·6 above that from deaths. In every other district throughout the province the mortality ratio exceeded that for births. The highest mortality recorded in any district was that of 87·9 per 1000 in Angul, and the next highest that of Puri (70·3) on the sea coast. Both these districts are in Orissa. On the other hand, Darbhanga (in Tirhut) lost only 30·5, Singhbhum (in Chota Nagpur) 31·1, and Patna also 31·1 per 1000; the respective ratios for the preceding quinquennium having been 38·0, 26·7, and 42·0. Taking the province as a whole the highest mortality was recorded in January, due to a continuance of the influenza epidemic of the preceding year. The infantile mortality ratio (214·5 per 1000 births) was less than that of 1918 (231·2). It varied from 119·6 in Darbhanga to 607·6 in Angul. Lantern lectures on child welfare and maternity work were given in some of the large towns, and articles on the subject published in the local newspapers. As regards mortality among different classes of the population the ratio for Hindus (who form about four-fifths of the total) was 40·9, for Mohammedans 31·5, and for Christians 24·3 per 1000.

Fevers: Influenza, Cholera, Plague.

The rise in general mortality (40·0 per 1000) as compared with the preceding quinquennium (37·0) was recorded chiefly under the heading of "Fevers" (28·1 compared with 24·4), and was due to influenza. 970,055 deaths out of the total 1,379,657 were registered under "Fevers." In the district of Angul (in Orissa) the "fever" mortality was 63·1 per 1000, as compared with 26·6 in the quinquennium. In Saran and Patna the ratios were only 17·3 and 17·6 respectively. Dr. S. N. Tiwari, D.P.H., officiating sanitary commissioner, who presents this report,[1] remarks that "only 10,765 deaths were reported from influenza throughout the whole province. This is obviously wrong. . . . The presumption is that the high mortality returned under fevers, in the first few months of the year, was due to the declining epidemic of influenza of 1918, which continued in 1919." Anti-malarial operations and free distribution of quinine were continued. Cholera caused 101,727 deaths (3·0 per 1000, the same as in the quinquennium, 1914–18). It was epidemic in the Orissa division, where the deaths numbered 42,217 (8·2 per 1000), and particularly in the district of Puri (12·8 per 1000). This province has an especial importance in regard to cholera on account of its three much frequented pilgrimage shrines (Puri, Gaya, and Deoghar). Besides the ordinary prophylactic measures the experiment of inoculating cholera contacts with anti-cholera vaccine was tried at Hurhuru in Hazaribagh district; 635 persons were inoculated, 8 were attacked within 18 hours, and 19 from 2 to 10 days after inoculation. Excluding the 8 (who must have been already infected before inoculation) the incidence after one injection was 3·5 per cent., compared to 12·0 previous to inoculation, and the mortality 42 per cent., against 62 per cent. A second injection was given to 433 persons, and amongst these not a single case occurred; while of 121 not inoculated, 24 were attacked and 14 died—i.e., 19·0 per cent. in incidence and 58 per cent. case-mortality. Out of 178,031 coolies recruited by the Tea Districts Labour Association 131,606 were inoculated without any untoward effects. There was less plague (0·4 deaths per 1000, compared with 1·5 in 1918 and 1·2 in the quinquennium). The small town of Tikari, in Gaya district, had 39 deaths (6·6 per 1000). It is very satisfactory to learn that the Temple authorities at Puri gave willing coöperation in disinfecting wells inside the temple and the sacred tanks at the time of the Rathjathra festival in July, when cholera was epidemic in the surrounding districts. This was done, Dr. Tiwari believes, "for the first time in the history of sanitary arrangements at Puri," and is a testimony to the care and tact of the sanitary authorities concerned. Improvements have been carried out in the drainage and general sanitation of the "New Capital," Patna; and in this connexion Mr. J. G. Alexander, officiating sanitary engineer, states that the year under review has been one of marked activity. The use of flat graded sewers to take the effluent from small septic tanks "has been found to be thoroughly justified in practice," and "augurs well for the success of the whole scheme designed on this principle."

Hospitals and Dispensaries.

In his report on hospitals and dispensaries[2] in Bihar and Orissa for the years 1917–19 Lieut.-Colonel H. Austen Smith, C.I.E., Inspector-General of Civil Hospitals, points out that the provision of dispensaries, even if extended (as is now being done), only partly meets the needs of the population, leaving the rural areas to some extent untouched. He advocates the extended use of travelling dispensaries, adequately equipped, while the assistant surgeon in charge would give advice regarding sanitation, investigate local outbreaks of disease, and generally help the people from a medical point of view. There were 20 travelling dispensaries in the province at the beginning of the triennium and 15 at its close, the average number of patients treated yearly being 76,305. The total number of indoor patients treated in all classes of hospitals and dispensaries was 65,319 in 1919, compared with 50,625 in 1916; the corresponding numbers of out-patients were 3,603,077 and 3,412,520. A large increase occurred in the death-rate of dispensary in-patients (5·68 per cent. in 1917, 7·20 in 1918, and 10·06 in 1919), partly due to general unhealthiness in some districts, and partly to be explained by the fact that over 6 per cent. were moribund on admission. Malaria was excessively prevalent, the yearly average of cases treated at hospitals and dispensaries having been 765,435, compared with 609,001 in the preceding triennium. The benefits of quinine are appreciated by the people, the amounts realised from its sale (in the form of pills and influenza tablets) having been Rs. 23,531, Rs. 29,202, and Rs. 26,920 in the three years, 1917–19 respectively. Lieut.-Colonel J. C. S. Vaughan, I.M.S., has ascertained that *Vitex peduncularis* (a plant largely used in Madagascar in the treatment of malaria and blackwater fever) is indigenous in the Ranchi district, and in use by the aboriginal tribes as a remedy for these affections. Good results have been obtained by treatment with infusions of the leaf, and further investigations are in progress. There was an increase of 7503 patients treated for venereal disease in 1917–19 over the preceding triennial period. This was apparently due to the increased number of syphilitic patients attending, since treatment by novarsenobillon injections has been adopted with considerable success. An additional leper asylum has been established at Cuttack, with accommodation for 232 patients. Radium therapy for cancer, keloids, &c., was undertaken by Lieut.-Colonel Vaughan at Bhagalpur in 1913, and has been continued by him at Ranchi with good results. The demand for this treatment is rapidly increasing, and it is proposed to establish a radium institute at this station, which is conveniently near Calcutta, and has a suitable climate.

Sickness and Mortality in Jails.

From the report on the jails[3] in Bihar and Orissa, in 1919 it appears that 9026 prisoners were present at the beginning of the year, and that the total number of prisoners of all classes received was 59,835, being an increase of 17,270 on the corresponding figure for 1918. The total number under care was therefore 68,861, and the daily average prison population 9763, compared with 9199 in the year preceding. Major W. Gillitt, C.I.E., I.M.S., officiating inspector-general of prisons, states that this increase "was doubtless due to the prevalence of acute scarcity throughout the province," leading to an increase in offences against property. Crimes against the person have shown an appreciable decline. The number of females convicted was more than double that in the previous year. There was consequently over-the left epididymis, associated with a large hydrocele which I considered was syphilitic. There was no history of this disease and he had a perfectly healthy family. The X ray examination seemed to confirm the suspicion of carcinoma, but there was a positive Wassermann, and on anti-syphilitic treatment the tumour had disappeared completely in three weeks.

[2] Patna, 1920.

[3] Administration Report for 1919. Patna, 1920.

The surgery of the spleen is now becoming one of the commonplaces of life in the work of an abdominal surgeon. Many of its diseases are curable by operative means. Without blood examination we should be helpless. In splenic anæmia, with its leucopenia with relative increase in lymphocytes, the enlarged spleen can be removed at slight risk with the prospect of cure. The patient is saved from gradually increasing ill-health and the later development of Banti's disease. The change in the blood after splenectomy is rapid and striking; within a few weeks the white cell count has returned to normal. The blood changes in splenomegalic jaundice are typical before operation, and equally striking is its post-operative recovery.

By our blood examination we are warned away from the enlarged spleen of splenomedullary leukæmia with its 100 per cent. death-rate. In the cases of latent carcinoma of the stomach with marked anæmia, blood examination at once tells us that it is not "pernicious" and hence should raise the suspicion of carcinoma.

Post-Operative Investigations.

I have dealt only with some of the more recent methods; of the no less important examination of fluids and solid materials removed at operation you are all as familiar as I. As reminders I might mention that the discovery of typhoid bacilli when the biliary passages are drained, or in stones removed at operation, enables us to take precautions against infection. The report on the fluid evacuated from the cyst confirms our diagnosis of its pancreatic origin, and the finding of malignant cells in a portion of tissue removed at an exploration gives us the indication for correct treatment.

Special Lesions.

Of all simple gastric diseases amenable to surgical treatment chronic duodenal ulcer is the most common; fortunately it is also the most easily diagnosed and has the best prognosis. Ninety per cent. at least are cured by gastro-jejunostomy, and less than 2 per cent. are failures. In this disease hyperchlorhydria is the rule, except immediately after a hæmorrhage. In a fairly large experience I have only met with two cases in which gastric acidity was lower than normal, excluding those with enormously dilated stomachs due to cicatrisation of old ulcers, in whom chronic gastritis may diminish gastric acidity; even in these the acidity is usually above normal.

With the "typical" history and the hyperchlorhydria, the diagnosis is more certain than that of any other simple abdominal condition. Unfortunately, only about 75 per cent. of cases have this "typical" history; in others the symptoms may suggest gall-stones or chronic gastric ulcer. I have recently operated on two patients in one week, both of whom had normal gall-bladders drained elsewhere and the ulcer overlooked. It is, however, by no means unusual to get coexisting gall-bladder disease. Jaundice as the result of the presence of a chronic duodenal ulcer is a far from uncommon complication, but one that rapidly clears after gastro-jejunostomy.

The right-sided pain may suggest renal colic. Several patients have come under my care with this diagnosis, who proved on investigation and operation to have chronic duodenal ulcers. The test-meal here is of the greatest assistance. We must, however, bear in mind in anomalous cases that an oxalate calculus in the kidney may give rise to hyperchlorhydria and hunger pain. In doubtful cases I always have the urinary tract X rayed. X ray examination after an opaque meal adds nothing to our certainty of diagnosis in the majority of cases and is not necessary; a hypertonic stomach with rapid emptying is the rule, and it is unusual to find direct evidence of the ulcer.

Chronic Gastric Ulcer.

In chronic gastric ulcer the test-meal is unfortunately of no diagnostic value; as a rule the condition is little removed from normal. Occasionally in ulcers that are active there may be hyperchlorhydria; in others, particularly with hour-glass stomach, there may be an absence of free HCl and a low total acidity. These cases are often diagnosed as carcinoma. In chronic gastric ulcer in men, in whom it is so much more common, the history is often as diagnostic as in chronic duodenal ulcer, but in women it may present extraordinary difficulties and certainty may be impossible.

The only direct evidence is that which may be obtained by X ray examination. The large penetrating ulcer and the constricting ulcer should be well seen. The small chronic ulcer on the lesser curvature, about the size of a shilling, that has passed through all the coats of the stomach may be demonstrated but is often missed. In every anomalous upper abdominal case X ray examination should be carried out. It must not be allowed the final word, for at the present time we cannot say that if X ray fails to reveal it no ulcer is present. The evidence must be balanced with that obtained by other means, particular importance always being attached to the history. In this connexion it must be remembered that the stomach is very responsive to lesions elsewhere in the abdomen, themselves curable by operation but not capable of X ray demonstration.

Carcinoma of the Stomach.

We now pass to a consideration of carcinoma of the stomach. The death-rate from this disease is unjustifiably high; yet it is safe to say that the greater part of it is preventable, since more than half the cases arise from a pre-existing chronic gastric ulcer. Early and efficient treatment of this condition will save many lives. In carcinoma originating without previous history of gastric trouble, the percentage of cases operable when first seen by the surgeon is appallingly low. This is not, in most cases, the fault of the patient, but of the profession. The patient usually seeks advice early enough, but the symptoms are so slight as not to be generally recognised and thus valuable time is lost. The usual history is that medicine is given, then a change of air ordered, or pyorrhœa is diagnosed and more valuable time wasted until the inevitable tumour can be felt.

There is only one safe rule—every case of digestive discomfort arising in an adult who has previously been in good gastric health, must be looked upon with suspicion. The first thorough examination will find or eliminate obvious causes—teeth, overwork, alcohol, disease of the genito-urinary or nervous systems—and the patient will be weighed. It is not humanly possible to examine by test and bismuth meals every case of this nature, but in those in whom thorough examination has revealed nothing to account for the symptoms these investigations should be done at once. In the remainder, what we consider the cause should be dealt with and treatment adopted for a month. If at the end of that time the patient is not well, sooner if he is not improving, test and bismuth should be given. In this type it is usual to find that free HCl is lost early, and that the total acidity is low. I consider this sufficient evidence to justify operation—if we wait for absolute certainty it usually means death to the patient. If an adult previously in good health develops discomfort after food, for which no cause can be found, and the test-meal reveals an absence of free HCl and a low total acidity, operation should be carried out without delay. Occasionally in growths near the pylorus there is, in the early stages, a great increase of gastric acidity; to know this should be sufficient.

THE LANCET, OCTOBER 1ST, 1921.

No. LIBRARY

An Address

ON THE VALUE OF PATHOLOGICAL AND X RAY EXAMINATIONS IN ABDOMINAL SURGERY.

Delivered at the Dorset County Hospital, Dorchester, at the Opening of the new Pathological Department and X Ray and Electrical Rooms on Sept. 21st, 1921,

BY JAMES SHERREN, C.B.E., F.R.C.S. ENG.,
SURGEON TO THE LONDON HOSPITAL, ETC.

SURGERY has a fascination possessed by few occupations. By its aid diseases and injury, incurable by nature alone or aided by altering the constitution of the body fluids, can be eradicated or assisted in such a way that natural processes are enabled to bring about a cure. This work can be carried out so that its benefits are obvious to the naked eye; it is the one direct method we have to-day of combating disease which is already established in the body. Enthusiastic as we may be about operative methods of treatment, we all look forward to the day when the causes of surgical diseases are known with certainty and measures can be taken to prevent their development. It is, however, only with the help of departments such as it has been my privilege to open to-day that this can be brought about. The establishment of these in hospitals and the recognition of the invaluable aid they can give is one of the greatest advances in modern surgery.

Surgery has many branches; that dealing with the abdomen is the one in which I take the greatest interest and led to the title of this address. It would, perhaps, be an exaggeration to say that there is no such thing as abdominal medicine, but the abdomen is a region of the body that should be approached with a surgical mind. Many lives would be saved and much suffering avoided if this were done. How many cases of carcinoma of the stomach, to take a common example, have been told that there was nothing seriously wrong, finally to seek surgical aid when the condition was too far advanced to be benefited. How many tragedies does this not call to mind! I recently saw a gentleman with an enormous inoperable mass in the abdomen who, on retiring from business nine months previously, developed suspicious gastric symptoms. His medical attendant wished him to see a surgeon; the patient's friends said "No—he will surely be operated on." He was diagnosed flatulent dyspepsia—allowed to go for a trip round the world and returned inoperable. Never a month passes but I see cases of this nature.

The surgeon is the only individual who has the correlated knowledge of symptoms, signs, and the actual condition of parts as seen during life. This clinical knowledge cannot be possessed by the physician. We have too often heard it said of patients —"he was afraid to go to a surgeon as he would be certain to operate." The public seem to think that surgery is synonymous with operating; this fallacy ought to be seriously combated. The modern surgeon is not an operating machine, although if he has to bring this art into play he should have a rapid and sure technique with the power of quick decision when faced with the unexpected.

THE STATUS OF A HOSPITAL DEPENDENT ON ITS SPECIAL DEPARTMENTS.

One judges of the value of the work done by a hospital, not by the beauty of its wards or the up-to-date nature of its operating theatres, valuable as these are in treatment, but by the special departments, particularly those for pathological and X ray investigation, and the use that is made of them. Without the facilities given by these, not only can there be no life in our work but no progress; the dry bones of surgery can only live when breathed upon by knowledge gained from such investigations.

Surgery is now so wide that no one individual can thoroughly master the whole of it and be equally at home in the cavity of the skull and in the abdomen; of those special branches of medicine dealing with the departments of which I have been speaking still less are we able to do the work ourselves even had we the necessary training. Team work is inevitable. It is, of course, impossible to have a team without a head; a cricket team without a captain stands as little chance of winning matches as a ship in which all men are equal has of ever reaching its destination. The only individual who possesses the necessary knowledge is the clinician; he alone knows the nature of the symptoms and realises, perhaps dimly, their meaning, and as a result of that valuable asset, clinical experience, he can determine the nature of the investigations required for diagnosis and of the special forms of treatment that may be requisite. His must be the guiding hand.

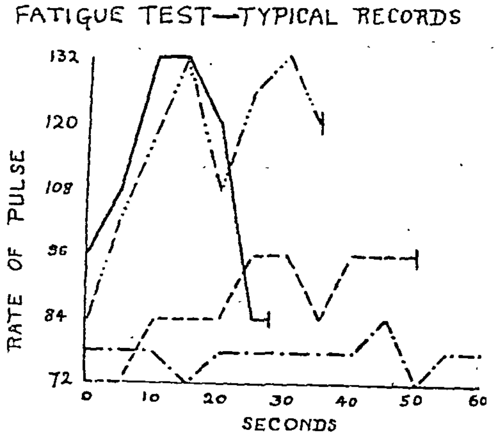
Before discussing the great value of these methods I should like to emphasise that, in the abdomen, the history as given by the patient must ever be the most important factor in diagnosis, which would, in most cases, be impossible on pathological and X ray investigation alone. In some branches of surgery the history may not be so important to diagnosis. X ray examination reveals the fracture and its nature; microscopic examination of a portion of an ulcer of the tongue tells us that we are dealing with malignant disease. But in investigating abdominal disease we cannot obtain such direct evidence, and these methods have to be fitted in with the history which is usually the last court of appeal. The functions of a pathological laboratory are manifold; not only have histological investigations to be carried out, often at short notice, but bacteriological and chemical. The clinical pathologist needs to be familiar with every method of investigation.

SPECIAL INVESTIGATIONS IN ACUTE CASES.

In acute abdominal emergencies no time should ever be wasted. A careful history must always be taken; this, with the symptoms and physical signs and examination of the urine, which ought never to be neglected, must be our guide. After all our reliance must be on ourselves. To await some special form of investigation while peritoneal infection or damage to intestine is possibly increasing is quite unjustifiable. In the less acute cases we may obtain much help; where no great danger is anticipated by delay every endeavour should be made to come to an accurate diagnosis before the abdomen is opened. For example, acute tuberculous peritonitis may sometimes lead to the suspicion of typhoid, a disease of protean types. Our laboratory colleague at once is able to tell us the blood reaction and its degree.

In the diagnosis of complications arising during recovery after operation we may get much help. To take, as an example, the disease of which there can be no doubt that surgery in the first few hours is the only justifiable treatment—appendicitis. Unfortunately we do not get all as early as this, and it is these late cases that often tax our skill to the utmost if we are to bring them to a successful termination. All may not be going well, there is a rise of temperature perhaps to 100° each night, and rectal examination and examination of the chest does not reveal the cause; a blood count will give us the warning of the formation of a residual abscess. Again, when there is suspicious dullness at the right base without displacement of the heart, X ray examination of the chest may show us the situation of the fluid—above or below the diaphragm. If below, we know from experience that it is certainly pus and also the great danger of delay—in these cases following appendicitis. I am a whole-hearted sceptic as to the value of vaccine treatment, in acute abdominal conditions at any rate. I have never known it do good so shall not discuss it.

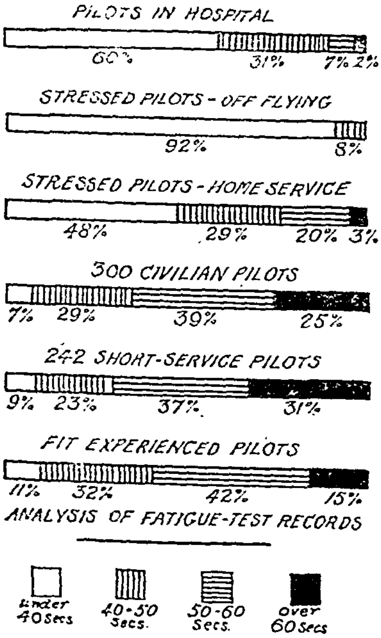
FIG. 3.



characteristic, and in all cases it is associated with marked flushing of the face and engorgement of the jugular veins, conditions which are not marked in the fit man. These forms of responses are charted in Fig. 3.

What exactly the test indicates it would be premature to try and say. More work is required on the exact physiological processes which are taking place. But a sufficient number of tests have been made as to the application to physical fitness and unfitness. The first standard for fitness for the test was set, as with the standards for other tests, by the examination of fit flying officers chosen by the executive, the standard for the tired and broken-down officer being similarly worked out. The remarks which have been made with regard to the breath-holding test—as to the test being in part a measure of the lung capacity for oxygen, as well as of the sensitivity of the subject to diminishing oxygen-tension—also hold good in respect of this test. So, too, does the comment as to the value of such tests in regard to the resolution of the subject. It is to be observed, however, that no matter how resolute a really unfit man may be, he will not be able to support the mercury for the time that a fit man does. Some figures concerning the application of the fatigue test have been given me by Lieut.-Colonel A. P. Bowdler, and they are charted in Fig. 4. It will be seen that, as with the breath-holding, pilots who may be said to represent the survival of the fittest—namely, successful demobilised flying officers, who wish to be granted short service commissions and other pilots desirous of continuing flying in commercial aviation—reach high standards on this test, in marked contrast to pilots who are on limited flying through stress or off flying altogether. It will be seen that, as with the breath-holding, the population of a hospital for flying patients has, on an average, a very poor capacity in this test. This is confirmed by the examination of over 400 for the records of both this and the breath-holding test.

FIG. 4.



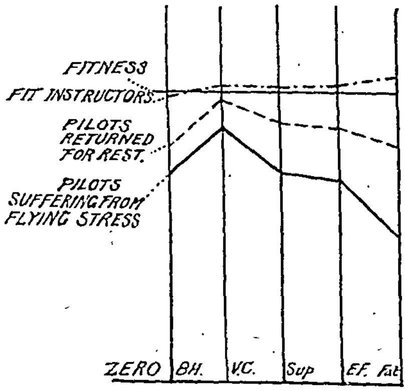
I will now give a few examples of the value of the tests considered as a whole; in assessing the physical fitness of the individual it must be remembered that in practice they are also employed in conjunction with other tests for circulatory efficiency and nervous stability. The normal standards taken for the tests may be summarised as follows: Breath-holding, 70 sec.; vital capacity, 4000 c.cm. (approx.);† supplemental air, 1600 c.cm. (approx.); expiratory force, 110 mm. Hg; 40 mm. Hg test, 50 sec. The falling away in efficiency due to flying strain may be shown shortly in the following table:—

TABLE III.

—	Breath holding in secs.	Vital capacity c.cm.	Supplemental air c.cm.	Expiratory force mm. Hg.	Fatigue in secs.
Fit instructors	69	4060	1620	112	52
Pilots returned for rest ..	57	3900	1400	95	40
Pilots broken down through flying strain	49	3480	1130	74	25

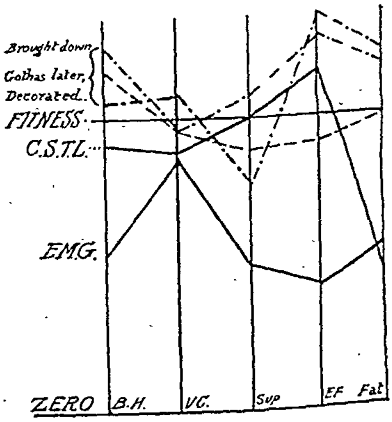
These are graphically recorded in Fig. 5; the value of the tests in overhauling an individual is shown in the results, which were obtained quite early during the time of working out the standards for the tests and of testing their possible value.

FIG. 5.



Graph showing how, in various respects, groups of pilots were below the normal line. B.H. = Breath holding. V.C. = Vital capacity. Sup. = Supplemental air. E.F. = expiratory force. Fat. = Fatigue.

FIG. 6.



Graph illustrating Table V.

The results in Table IV. were obtained at one of the first aerodromes visited for the examination of efficient flying officers. Through a misunderstanding all instructors were sent, and not the fit ones only. It will be seen from the results that the fit officers are easily distinguished from those who were either unfit for flying on medical grounds or who had been placed on limited flying or taken off flying for a rest by the executive.

Table V. shows results obtained at a home defence aerodrome where I had gone to obtain results from fit officers. On arrival there I was told that one

---

† These experiments were made before Dreyer's tables were available.

I have very briefly sketched out what should be looked for in the routine X ray examination of a gastric case. Before dealing with its value *in diagnosis in the various gastric lesions* I must speak shortly of its utility in diseases of the colon.

VALUE OF X RAY INVESTIGATION IN DISEASES OF THE COLON

Except in the unusual cases in which we wish to estimate the stay of intestinal contents in this part *of the alimentary canal, the opaque material* is usually and in my opinion, better administered by enema. *We are able to demonstrate angulations, enlarge*ments, and the changes caused by *diverticulitis all* of the utmost importance. In the diagnosis of carcinoma it may be of the greatest help. Every suspicious case should be so investigated by X *rays* as a routine. Here, again, I would warn against accepting a negative finding if it does not agree with the *clinical diagnosis*. The possibility of carcinoma of the lower bowel should *never* be dismissed until examination with the sigmoidoscope has been carried out.

Malignant disease of the colon is very amenable to surgical treatment and the prognosis is good; yet *how seldom do we see cases of this* disease when they are really operable, not because the condition does *not produce symptoms either pain or diarrhœa* but because so little attention was paid to them. Every *complaint* of abdominal pain or discomfort or of anything abnormal should call for investigation by *all the means at* our disposal. This is one of the reasons for the statement at the beginning of my *address*—all abdominal cases should be considered surgically.

The early *symptoms of carcinoma of the colon* are usually *irregularity of the bowels or painless diarrhœa*. Sometimes there is colicky pain—general or it may be in the right iliac fossa. This site for the pain has caused many errors in diagnosis; for example, I was asked to operate on a patient for intestinal obstruction on his landing from New York *after a recent* operation in Canada for appendicitis. On seeing the patient I found that the appendix had been removed for pain confined to the right iliac fossa, due to carcinoma of the pelvic colon. This is by no means an uncommon error. Much more generally recognised is the *difficulty in diagnosis between* certain cases of carcinoma *of the cæcum and a mass due to disease* of the appendix. In both there may have been attacks of colicky *pain in the* mid line. I have known mistakes made in both directions. Usually the history *and physical* examination is sufficient to enable the diagnosis to be made; X ray *examination after an opaque enema* usually *clinches* it *at once*, revealing in the one the irregular filling *defect, in the other the narrowing of the cæcum* from external pressure.

Left-sided pain is rarely a symptom of carcinoma of the pelvic colon; it is much more common in *disease of the gall-bladder* and stomach. I have had several patients with gall-stones *sent to me as carcinoma of sigmoid*. Adult patients with looseness of the bowels must be seriously investigated and X ray examination is one of the most valuable methods and should never be neglected.

The help given by the investigation of the stools not only in *inflammatory disease of the colon but in* pancreatic and obstructive jaundice is often of the *greatest use in diagnosis and treatment*.

PATHOLOGICAL CHEMISTRY OF THE STOMACH

It is no exaggeration to say *that without access* to a pathological *laboratory* efficient abdominal surgery is *impossible*. In dealing with diseases of the stomach chemical pathology is of great assistance. I attach importance to the examination of the gastric contents *after a test meal*, both in diagnosis and prognosis. I have been in the habit of employing *the Ewald test breakfast*. With regard to the fractional test meal much work is still being done *and valuable physiological information obtained, but for surgical work it* has at present no advantage over the simpler method of examining the gastric contents one hour after the meal. Some years must elapse before sufficient observations, checked by operative investigation, have given data to render it so satisfactory a *guide*.

Certain precautions are necessary; the meal must be examined in the same *laboratory under the same* staff. All mine have been done by Dr. P. N. Panton in the manner which he described with Dr. H. L. Tidy. It has its greatest use in diagnosis in chronic duodenal ulcer, and certain cases of carcinoma, in prognosis after gastric operations.

Considerable discussion has taken place with regard *to the action of gastro-jejunostomy in bringing about* the healing of an ulcer and in preventing the formation *of other chronic ulcers elsewhere*. I have shown by numerous specimens, obtained post mortem and by examination at *operations performed* for other conditions up to 11 years after, that chronic ulcers of the stomach and duodenum if they are "free" will heal and remain healed after a gastro-jejunostomy correctly performed. Also that the formation of ulcers in the region of the anastomosis is dependent upon gastric acidity. The operation is not entirely or in my opinion chiefly mechanical; the change it produces in the chemistry of the stomach *is of great importance*. *By the new opening it allows* rapid emptying of the stomach and counteracts pyloric spasm but before long food leaves again by the pylorus with no ill effect. It should immediately abolish the free HCl and diminish by from half to two-thirds the total *gastric acidity*. *This it does in at least 90 per cent of cases and in these success is* certain; no *fresh ulceration can take place* under these circumstances unless unabsorbable material *has been used*. This lowered acidity is permanent; at least I have known it persist for 11 years after gastro-jejunostomy.

There are many interesting details with regard to *what prevents*, in some few cases, lowered gastric acidity after gastro-jejunostomy. There is one very fertile cause that I must mention—pyloric exclusion. No attempt should ever be made to bring this about. If ulcers in the pyloric region have to be directly *dealt with it should be in such a manner that the* pylorus is *enlarged and not excluded*. Every patient *upon whom gastro-jejunostomy* has been carried out for the cure of ulcer should have *a second test meal* 11 days after operation and if gastric acidity is not lowered although the original ulcer will heal fresh ulceration in the region of the anastomosis *may occur* unless medical measures can be *found which will* bring about the *desired change*. Test meals are, *therefore, of great importance in prognosis*.

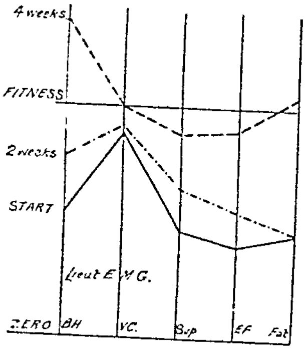
BLOOD EXAMINATION

*I must deal briefly with one other side of patho*logical work—blood examination. The abdominal *crises of tabes have led many surgeons astray*, and many gastro-jejunostomies were done for this *condition when the indications for its performance* were less sure than now. Still it does present *puzzling features and the only safe rule is always to* suspect. Examination *of the central nervous system* should be part of the routine in investigating every chronic abdominal case. A *Wassermann* reaction and examination of cerebro-spinal fluid may be necessary to confirm our suspicions. Again we are sometimes puzzled, and have opened an abdomen *for a mass in the gall-bladder region with symptoms suspicious of gall-stones* which proved to be a gumma, when the diagnosis would have been clear had we been thinking of this condition and had a Wassermann done.

Syphilitic disease *of the stomach* should be kept in mind. Last summer a patient *came to* England *from abroad to consult me* with regard to the possibility of removal of a large tumour of the stomach *thought to be malignant*. On examining there was a gastric tumour with all the characteristics *of a* carcinoma of that organ. I also found a swelling in decorated for bringing down Gothas which were raiding London. Fig. 6 illustrates Table V.

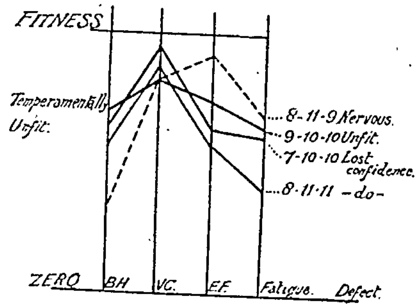
As showing the value of treatment, rest, and open-air exercise, I give (3a and 6b and c) the results obtained some time later upon the non-efficient officers. The progress of recovery of physical efficiency of Lieutenant E. M. G. is seen in the graph (Fig. 7). Although he recovered to this extent physically it is worth recording that he continued to suffer for a time from "anxiety neurosis." As regards the value of the test in assessing physical efficiency, it is interesting to compare the result in these cases with that of R. G. N. (Table VA.), who, although advised to give up flying for the time, asked to be allowed to continue to fly on limited flying. At the end of six weeks he returned stating that he felt that he could not continue flying any longer and that he would be glad to get away from it for a time.

FIG. 7.



Other examples could be given of similar cases which were met with during the period of investigation of the tests. That such a condition is not necessarily due to the length of time of flying indulged in is well seen in Table VI. which is taken from the results of over 300 officers or cadets examined during their period of training. All were found unsuitable for further flying, but it is noticeable that those who had developed nerves or lacked confidence and did not wish to continue flying present a marked contrast in physical efficiency to those who had no air sense, who were heavy on controls, or who made bad landings, and were disappointed at being "stood off" from flying.

FIG. 8.



Note.—The figures in the "fatigue" column in this and the following graph indicate variation in pulse-rate for five seconds ($\frac{1}{12}$ min.) during the fatigue test—e.g., 8–11–9 means that the pulse in five-second periods started at 96 per minute, went up during the test to 132, and fell again to 108.

FIG. 9.

DEPOT CADETS.

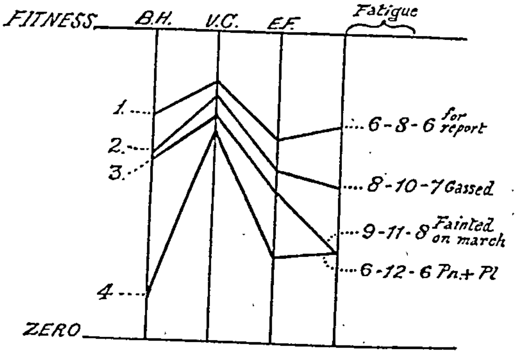


TABLE VIII.

Initials.	Age.	Breath held in secs.	Vital capacity in c.cm.	Supplemental air in c.cm.	Expiratory force in mm. Hg.	Secs. of sustaining 40 mm. Hg by blowing.
G. E. B.	17 11/12	55	4200	1300	80	42

D. H.	19	63	—	—	60	40
C. T. M. H. ..	19	42	3800	—	40	33
F. W. C.	22	61	4100	—	100	30
F. C. B.	23 2/12	63	4300	1800	60	35
F. R. B. W. ..	21 6/12	55	4100	1700	80	37
C. T. Y.	18 2/12	48	3800	1700	100	35

The falling away in efficiency of four of these subjects is shown in the graph (Fig. 8).

A similar condition of inefficiency may arise in cadets who have never been near an aerodrome, but who either have not sufficient physical stamina for military training or who have been debilitated by illness. The figures in Table VII. are taken from the records of 54 cadets reported upon before being posted to an aerodrome.

Cases 1–4 are graphically represented in Fig. 9 in such a manner that the falling away from standard in these tests is well demonstrated.

Finally, as showing that a similar condition of bodily inefficiency may be found among individuals who are deemed more or less normal members of the community, I give the results obtained during the period of experiment upon the tests by the examination of a number of individuals (mostly youths of 17 to 19 years) who, being conscripted for military service during the war, presented themselves for an opinion as to their suitability for aviation. (Table VIII.)

Candidates 1 to 11 had already been rejected by the medical examiners before the tests were taken. In candidates 12 to 15 an opinion was asked for by the assessor, who, although he did not feel the candidates were suitable, was unable to give an exact reason for this opinion. It is seen that in these four cases the tests afforded valuable help in indicating the physical inefficiency of the subjects in question.

COVENTRY AND WARWICKSHIRE HOSPITAL.—On Sept. 21st the general committee of the Coventry and Warwickshire Hospital, faced with a bank overdraft of £36,216 and an average working loss of £1000 a month, decided that in view of the present decline in income drastic economic action was necessary. The only possible course appeared to be the closing down of one block of the hospital, known as the White Wards, and this was reluctantly agreed upon. The number of beds will be reduced by 66, and a considerable saving will be effected in expenditure on account of staff and overhead charges.

I have never had an opportunity of seeing the result of X ray examination in an early case; at the time I most often see the patients the diagnosis is so obvious that it is usually a waste of time to have this done. It has been stated that X ray examination is useful in judging of the operability of a case of carcinoma of the stomach. This may be so in a few instances, but had I acted on this assumption many patients who are well to-day would have been dead or leading miserable lives as invalids. Never defer operation because it is the opinion of the X ray colleague that no growth is present or the case is inoperable. I have several times known cases of simple chronic ulcer returned from X ray examination with the definite diagnosis of inoperable malignant growth, and cases of carcinoma with the report "no evidence of any gastric lesion." A case should only be judged inoperable before opening the abdomen if enlarged glands are present above the left clavicle, or if rectal examination, which should be a routine in every abdominal case, reveals secondary deposits in the pelvis.

In the more common type of carcinoma, that following a many years history of chronic ulcer, the test-meal is of no value; the result is the same as that found in chronic ulcer without this complication. In the same way the opaque meal may not help—simply showing the crater of an ulcer or being returned as negative. This is as we should expect when we consider the difficulty even after the abdomen has been opened; in some cases it is only on microscopical examination that the diagnosis is made. It is the history that usually makes one suspicious that this complication may have occurred. After a period of years in which the patient has had attacks of pain at a regular hour after food, lasting meal after meal, day after day for weeks, with or without occasional vomiting, interspersed with periods of perfect or almost perfect digestive health lasting for months, an attack comes which, instead of passing away in the usual time, continues, or the symptoms alter, the pain becoming constant. Change in the nature of the symptoms, or their continuance, points to some complication having occurred, either adhesion to and erosion of neighbouring organs, particularly the pancreas, or the development of a stricture, hour-glass stomach, or the onset of carcinoma. X ray examination may help, but symptoms such as these mean that a long delayed and long necessary operation must be done.

Gall-stones.

Little help can be obtained in the diagnosis of gall-stones from X ray or pathological investigations. It may be possible in the future to say as the result of X ray examination that no stones are present, but this, although of value, would not exclude serious disease producing biliary colic. Many anomalous symptoms owe their origin to cholelithiasis; I have already mentioned attacks of pain in the left iliac fossa. I have published several cases in which the symptoms of carcinoma of the stomach were mimicked with exactitude; in gall-stones low gastric acidity is the rule and absence of free HCl common. Occasionally the regularity of the pain is such that the inevitable diagnosis is chronic gastric or duodenal ulcer. When we remember how frequently gall-stones are found complicating other abdominal diseases, the problem becomes more difficult. It holds a lesson for us all—never be content with the lesion found: if the condition of the patient will permit the whole abdomen must be examined. This warning is particularly necessary in dealing with disease of the appendix. No term has been more abused than chronic appendicitis; it has been made to cover many sins other than its own. Appendicular dyspepsia is a very real condition—diagnosable usually only by exclusion—and none of its symptoms are referable to the right iliac fossa. I teach at hospital that it is legitimate to diagnose appendix dyspepsia but not to act upon it. By this I mean that one should not in these cases remove the appendix through a small incision in the right iliac fossa: the whole abdomen should be explored through a right paramedian incision in which the rectus is pulled out. By this method the size of the incision is of no moment in the strength of the abdominal wall after operation; the muscle falls back into its place and ventral hernia is impossible.

CONCLUSION.

I am afraid my remarks have been rambling, and for this I must apologise. I hope I have been able to point out a few of the great advantages of such departments as I have opened to-day in one small branch of surgery. Their utility, not only to the hospital, but to the whole district served is so great as to be inestimable.

The Milroy Lectures

ON

RESPIRATORY EFFICIENCY IN RELATION TO HEALTH AND DISEASE.

Delivered before the Royal College of Physicians of London

BY MARTIN FLACK, C.B.E., M.B., B.CH OXON.,
WING COMMANDER, ROYAL AIR FORCE MEDICAL SERVICE.

LECTURE II.—(*Concluded*).*

SPECIAL ROUTINE TESTS.

The Endurance or "Fatigue" Test.

THE test of sustaining 40 mm. of mercury with the breath held arose out of an endeavour to see if any noticeable fatigue could be elicited by getting the subject to blow every few seconds the mercury as high as possible, thereby getting a fatigue curve. This proved to be too wearisome, so the idea came to hold the mercury at a given height as long as possible. The height of 40 mm. was fixed upon, partly because certain subjects could not blow the mercury much above this height, but also because it was thought that this pressure, besides throwing a certain amount of work upon the expiratory musculature, would also cause a distinct but not unbearable or dangerous resistance to the circulatory through the lungs, thereby possibly giving value to the test as throwing light upon the circulatory condition of the subject. The idea of counting the pulse arose from this point of view, and it has proved to be a valuable adjunct to the test. The subject has no control over the behaviour of his pulse, and it has been found that the fit man differs very greatly from the unfit man in this respect. In the fit man the rate of the pulse every five seconds is not materially affected during the time that the mercury is sustained; in the slightly less fit the pulse rises gradually in rate until just before the end. The average time for the fit individual is 50 to 60 seconds. In a man probably unfit for flying, on the other hand, the pulse is immediately increased in rate and may stay so, with variations due mainly to error in counting by five seconds, as, for example, from seven per second before the test to 10, 11, 10, 11, 10, 9, 10 in five-second periods during the test. This type of response, however, is certainly not so definitely an expression of unfitness as one in which, after a transitory period of quickening, the pulse rapidly falls to the initial rate or even below. This type of response has been found to be associated with the most marked cases of flying strain. The length of time during which the mercury is supported is short, 15 to 25 seconds, and in that time the pulse-rate, in five-second periods, may vary from 96 per minute to 144 or 156 per minute and fall again to 72. Such cardio-motor instability is very lower fragments of the tibia and fibula are carried back with the displaced foot, both fragments forming a large open angle with their corresponding shafts. (See Fig. 3.)

---

* Lecture I. and the first part of Lecture II. were published in THE LANCET of Sept. 17th and 24th respectively. Lecture III. will appear in a coming issue.

Disastrous Third Degree.

This last is the fracture to which I now wish to call particular attention. My experience of the treatment of this fracture, of which very many cases have passed through my hands since I first recognised it early in my career, is that it is very often impossible to replace and retain the fragments in accurate apposition by means of manipulation and splinting alone. That this is certainly the experience of others is fair to assume from the conditions presented by those cases which have come under my observation some months after treatment. As far as I could gather from the history of these patients, they were regarded as ordinary examples of Pott's fracture, and were all subjected to the process of so-called "setting" which entailed the administration of an anæsthetic. The limb was then put up in a splint and a perfect result was promised. Some were radiographed subsequently, but no mention was made to the patient of any residual displacement, if it was observed, and certainly no effort was made to rectify it.

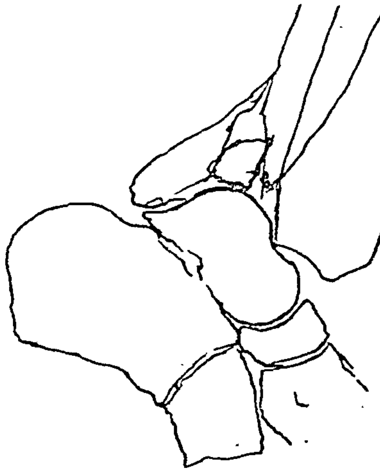

FIG. 3 represents diagrammatically the relations of the broken bones to the foot at time of receipt of the injury.

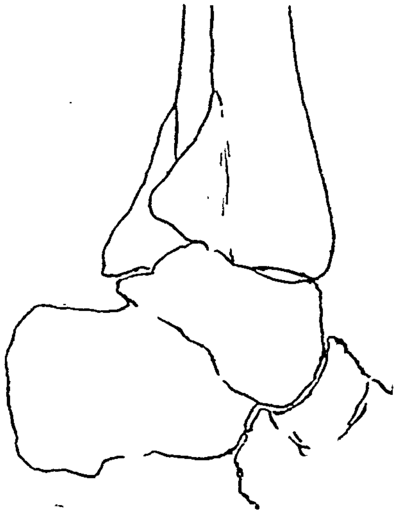

FIG. 4 shows the relationship of the bones to the foot after several months have elapsed since the receipt of the injury. The front of the tibia has formed a new joint with the upper aspect of the head of the astragalus, while the fragments of the tibia and fibula have blended together to form an irregular mass which no longer permits of free flexion and extension of the ankle-joint. The articular surface of the astragalus has also undergone extensive changes in form.

It is unfortunate that once the fragments of the tibia and fibula have united in their displaced position the possibility of separating the tibial fragment and of restoring it to its normal position is very small. This is due to the fact that the end of the tibia has formed for itself a new joint with the upper surface of the neck of the astragalus and the adjacent portion of the tibial facet on the astragalus, while the fibular and tibial fragments, having united with the shafts, articulate with the rest of the facet on the astragalus—which has become much altered in form—with the process of bone behind it. (See Fig. 4.)

In the other varieties of adduction and abduction fractures it is usually possible by operation to replace the inner malleolar and fibular fragments in their normal position and to restore the function of the joint. In this particular fracture the presence of the displaced tibial fragment forms what is practically an insuperable obstacle.

Surgeons have no valid excuse for the very disastrous results that follow these methods of treatment, since it is possible to obtain excellent radiograms in most places in the country. What has puzzled me is that none of these unfortunate patients had resorted to the law courts, although the failure of the surgeon to perform his duty is only too obvious to the meanest intelligence, in view of the facility with which radiograms can be obtained by patients in the present day.

Treatment.

Apart from cases in which the bones are fragile and comminuted from advanced age or prolonged alcoholic excess, this fracture can be dealt with successfully by operation. A vertical incision exposing the fibular fracture enables the surgeon by suitable manipulation to restore the fragments of the fibula to their normal relationship. The accurate adaptation of the fibular fragments entails that of the tibial fragment, since the fibular fragments cannot be approximated unless the tibial section fits into the gap in the tibia. The fragment of the internal malleolus also falls automatically in position and remains so. The fibular fragments can then be secured accurately in position by means of a plate and four screws, supplemented in a few instances by the use of an encircling loop of steel wire.

Much of the difficulty and failure which the surgeon experiences in the treatment of fractures is due to the fact that while in his preliminary studies he is called upon to acquire a transitory knowledge of much that is relatively useless to him in the efficient performance of his profession, the fundamental principles of mechanics upon which a knowledge of the function of the skeleton and soft parts and of the treatment of the variations they undergo from injury or disease is absolutely essential, are excluded from his education. The fault lies not with the surgeon but with the teacher.

NUTRITION AND GROWTH ON DIETS DEVOID OF TRUE FATS.

BY J. C. DRUMMOND, D.Sc., F.I.C.,

AND

KATHARINE H. COWARD, M.Sc.,

BEIT MEMORIAL RESEARCH FELLOW.

(*From the Biochemical Laboratories, Institute of Physiology, University College, London.*)

THE question as to whether fats are or are not necessary components of the diet of higher animals has always presented great interest to physiologists, but in spite of much research work and many theories no definite answer has as yet been given. As was pointed out by Drummond (1919) no solution of this problem was possible until it had been found practicable to separate the so-called fat-soluble vitamin from the true fats, because experiments of long duration—and experiments only extending over a period of a few days are useless in this study—in which diets nearly or wholly devoid of fats have been given, have of necessity entailed the absence of adequate amounts officer had developed "nerves" and had to be taken off, and that another was tired and was landing badly and was probably unfit to fly. I asked that they should be sent in with the other officers. From the results obtained the opinion was offered that No. 6 was the officer who had broken down, this on account of his poor performance in all the tests. In this case the small supplemental air is especially noticeable. No. 6, as the 40 mm. Hg test well shows, was the officer showing signs of early stress. With regard to the other officers, who were all very fit, it is interesting to record that three were subsequently

lower fragments of the tibia and fibula are carried back with the displaced foot, both fragments forming a large open angle with their corresponding shafts. (See Fig. 3.)

Disastrous Third Degree.

This last is the fracture to which I now wish to call particular attention. My experience of the treatment of this fracture, of which very many cases have passed through my hands since I first recognised it early in my career, is that it is very often impossible to replace and retain the fragments in accurate apposition by means of manipulation and splinting alone. That this is certainly the experience of others is fair to assume from the conditions presented by those cases which have come under my observation some months after treatment. As far as I could gather from the history of these patients, they were regarded as ordinary examples of Pott's fracture, and were all subjected to the process of so-called "setting" which entailed the administration of an anæsthetic. The limb was then put up in a splint and a perfect result was promised. Some were radiographed subsequently, but no mention was made to the patient of any residual displacement, if it was observed, and certainly no effort was made to rectify it.

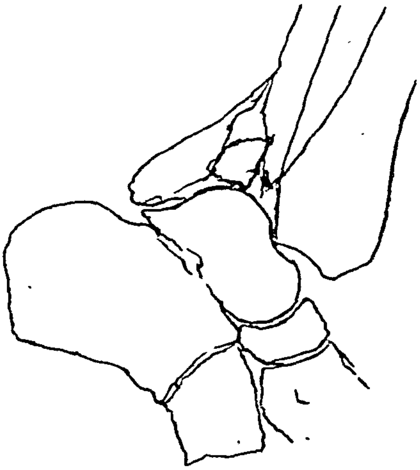

FIG. 3 represents diagrammatically the relations of the broken bones to the foot at time of receipt of the injury.

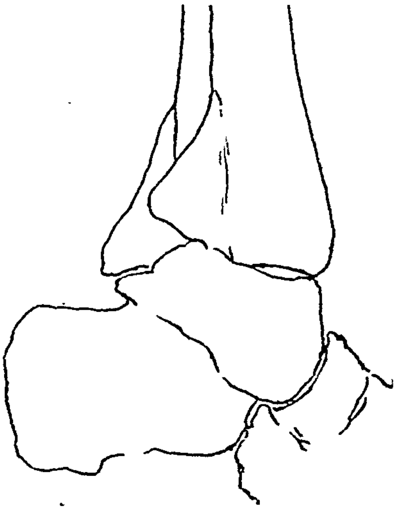

FIG. 4 shows the relationship of the bones to the foot after several months have elapsed since the receipt of the injury. The front of the tibia has formed a new joint with the upper aspect of the head of the astragalus, while the fragments of the tibia and fibula have blended together to form an irregular mass which no longer permits of free flexion and extension of the ankle-joint. The articular surface of the astragalus has also undergone extensive changes in form.

It is unfortunate that once the fragments of the tibia and fibula have united in their displaced position the possibility of separating the tibial fragment and of restoring it to its normal position is very small. This is due to the fact that the end of the tibia has formed for itself a new joint with the upper surface of the neck of the astragalus and the adjacent portion of the tibial facet on the astragalus, while the fibular and tibial fragments, having united with the shafts, articulate with the rest of the facet on the astragalus—which has become much altered in form—with the process of bone behind it. (See Fig. 4.)

In the other varieties of adduction and abduction fractures it is usually possible by operation to replace the inner malleolar and fibular fragments in their normal position and to restore the function of the joint. In this particular fracture the presence of the displaced tibial fragment forms what is practically an insuperable obstacle.

Surgeons have no valid excuse for the very disastrous results that follow these methods of treatment, since it is possible to obtain excellent radiograms in most places in the country. What has puzzled me is that none of these unfortunate patients had resorted to the law courts, although the failure of the surgeon to perform his duty is only too obvious to the meanest intelligence, in view of the facility with which radiograms can be obtained by patients in the present day.

Treatment.

Apart from cases in which the bones are fragile and comminuted from advanced age or prolonged alcoholic excess, this fracture can be dealt with successfully by operation. A vertical incision exposing the fibular fracture enables the surgeon by suitable manipulation to restore the fragments of the fibula to their normal relationship. The accurate adaptation of the fibular fragments entails that of the tibial fragment, since the fibular fragments cannot be approximated unless the tibial section fits into the gap in the tibia. The fragment of the internal malleolus also falls automatically in position and remains so. The fibular fragments can then be secured accurately in position by means of a plate and four screws, supplemented in a few instances by the use of an encircling loop of steel wire.

Much of the difficulty and failure which the surgeon experiences in the treatment of fractures is due to the fact that while in his preliminary studies he is called upon to acquire a transitory knowledge of much that is relatively useless to him in the efficient performance of his profession, the fundamental principles of mechanics upon which a knowledge of the function of the skeleton and soft parts and of the treatment of the variations they undergo from injury or disease is absolutely essential, are excluded from his education. The fault lies not with the surgeon but with the teacher.

NUTRITION AND GROWTH ON DIETS DEVOID OF TRUE FATS.

BY J. C. DRUMMOND, D.SC., F.I.C.,
AND
KATHARINE H. COWARD, M.SC.,
BEIT MEMORIAL RESEARCH FELLOW.
(From the Biochemical Laboratories, Institute of Physiology, University College, London.)

THE question as to whether fats are or are not necessary components of the diet of higher animals has always presented great interest to physiologists, but in spite of much research work and many theories no definite answer has as yet been given. As was pointed out by Drummond (1919) no solution of this problem was possible until it had been found practicable to separate the so-called fat-soluble vitamin from the true fats, because experiments of long duration—and experiments only extending over a period of a few days are useless in this study—in which diets nearly or wholly devoid of fats have been given, have of necessity entailed the absence of adequate amounts

THE DISASTROUS RESULTS OF CERTAIN ABDUCTION FRACTURES OF THE ANKLE-JOINT.

BY SIR W. ARBUTHNOT LANE, BART.,
M.S.LOND., F.R.C.S.ENG.,
CONSULTING SURGEON, GUY'S HOSPITAL, ETC.

A SEQUENCE of consultations on the disastrous results of the surgical treatment of a fracture of the ankle-joint which I described for the first time very many years ago has impelled me to write the following short paper on the subject, since the mode of production of this fracture and its characteristics seem to have escaped the attention of the surgeon. As a consequence it receives no efficient treatment, with the unfortunate result that the patient is rendered permanently lame since little or nothing can be done to remedy the disability after the lapse of some weeks or months. I call attention to the details of this fracture with less hesitation since, with the exception of the writings of Dr. Artemio Zeno, the distinguished professor of surgery of the Litoral University of Rosario, I do not think I have ever seen the method of its treatment correctly referred to. It is certainly not an uncommon fracture, while the deformity and disability that is associated with it are most distressing. I called it the "third degree of abduction fracture of the ankle-joint." Many years have elapsed since I dealt with the mechanics of the ankle-joint, which were incorrectly described in anatomical text-books, when I showed that under the term Pott's fracture two distinct and opposite conditions were comprised. They were the results of an excessive amount of force applied to the ankle-joint in the positions of adduction and abduction. All these results had been blended into one confused mass by Pott and by the surgeons who followed him, while in anatomical and surgical works impossible diagrams were inserted to illustrate what was supposed to represent a Pott's fracture. The treatment of these fractures by splints was based largely on the supposed accuracy of these diagrams and was consequently comparatively futile. I note that the more recent editions of such books as Gray's Anatomy have discarded the ridiculous old diagram employed to illustrate Pott's fracture and have replaced it by a rough compromise. I will therefore make no apology for referring in some detail to the conditions which result from excessive adduction and excessive abduction of the ankle-joint.

Degrees of Adduction.

If the foot is *adducted* with a force greater than the skeleton is able to bear two varieties of fracture may result:—

(1) The direct impact of the facet on the inner aspect of the astragalus upon the internal malleolus results in a more or less vertical fracture of the tibia, the line of fracture passing upwards in such a direction as to carry away the internal malleolus and a triangular area of the shaft of the tibia. As this fragment is displaced upwards the gap between the malleoli is widened and the grip of the tibia and fibula upon the astragalus is rendered less secure than it was. (See Fig. 1.)

(2) If forcible adduction be continued after the internal malleolus has been broken, strain is exerted through the external lateral ligament on the outer malleolus sufficient to break the fibula transversely over the lower end of the tibia. The fibular fracture is usually somewhat scrunched. (See Fig. 2.)

It is obvious that should any difficulty be experienced in placing the fragments in either of these fractures in accurate apposition, the best possible result can be obtained by securing the internal malleolus in position by means of a plate and three screws, an operation which makes little demand on the skill of the surgeon. At the worst, except in a few cases, neither of these fractures is followed by serious disability.

Degrees of Abduction.

If the foot is *abducted* with a force greater than the skeleton can bear, fractures of three degrees of severity may ensue.

(1) In this movement, the areas of the articular surface of the ankle-joint which sustain the greatest pressure are the anterior portions of the facet on the external malleolus and on the astragalus. In consequence of this pressure on the front of the *malleolus a torsion* fracture of the fibula results. The situation of this fracture may vary within wide limits; it is never transverse, as originally described and illustrated diagramatically in the text-books, but is very oblique, or in some cases nearly vertical. If the fracture extends through the malleolus there may be no displacement of fragments, and the injury may only be seen in a radiogram taken from side to side. In no case of suspected abduction fracture should the surgeon be satisfied to express an opinion solely from the examination of a radiogram taken from before backwards. If the fracture be through the shaft of the fibula above its articulation with the tibia the displacement may be very *considerable and* correspondingly difficult to replace.

FIG. 1.

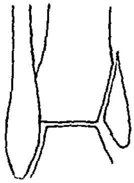

FIG. 2.

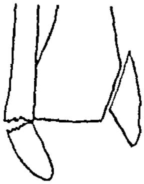

FIG. 1.—Fracture of tibia and carrying away of internal malleolus as a result of direct impact of facet on inner aspect of astragalus upon internal malleolus.

FIG. 2.—*Forcible adduction being continued after breaking of internal malleolus,* fibula breaks transversely over lower end of tibia as result of strain exerted through external *lateral ligament* on external malleolus.

(2) If the foot is displaced still further outwards strain is exerted through the internal lateral ligament upon the internal malleolus, which may be broken transversely. Occasionally the ligament may be ruptured instead.

These two fractures are met with fairly frequently. In many instances the displacement is trivial, and *in most a moderately good result may be obtained by splinting, controlled by radiography.* When the surgeon is unable to *bring the fragments into* reasonable apposition and to retain *them*—especially in patients in whom a joint affording a normal security is of great importance—the exposure of the fibular fracture, the accurate restoration by means of traction and forceps of this bone to its normal form, and its retention by means of a plate and four screws gives a perfect result. The internal malleolus falls automatically into position and does not require to be fixed by a plate. The exception to operative measures is when the patient is old or alcoholic and the bone is very fragile or severely comminuted. The difficulty that this particular fracture presents is that the *lower fibular fragment* consists of a long sharp spike, extending upwards and backwards, which has to be fitted and secured to the end of the shaft of the fibule.

(3) If the foot is abducted with still greater force the pressure exerted on the lower fragment of the fibula may by its strain upon the interosseous ligament *tear off a* wedge-shaped area of the lower end of the tibia of variable size having its base downwards. This fragment includes a varying proportion of the articular *facet* on the tibia. The ends of the shafts of the tibia and fibula are displaced forwards, the former resting upon the neck of the astragalus and upon the anterior portion of its tibial facet, while the

now reached maturity and it is hoped to continue the experiment further to ascertain whether any remote effects of the deficiency of true fats may be observed by changes in the capacity to breed and rear the young. The fact that we have obtained normal growth in rats from weaning to maturity on diets deprived as far as possible of all traces of neutral fats indicates that this class of foodstuff is not essential to the nutrition of these animals. (Growth curves in Figure.)

It is not intended to review the whole subject here, since the results will be published in a more complete form later. We may emphasise the truth of the remarks made by Osborne and Mendel in the paper to which we have referred, on the confusion which has arisen in the literature on this question through failure to recognise the disturbing factor introduced by the association of the vitamin with some fats and not with others. Our results support one opinion held by Hindhede (1920) who claims that fats are dispensable provided that a sufficient supply of vitamins is ensured.

Summary.

Young rats have been grown from weaning to maturity on diets, deprived as far as possible of neutral fats, and have shown normal development and behaviour. It is intended to ascertain whether the capacity for breeding and rearing the young is in any way inhibited by such diets.* More deaths were encountered amongst the animals on the fat-free diets than amongst those receiving fats. It would appear that neutral fats are, from a purely physiological standpoint, dispensable constituents of a diet, provided the other foodstuffs supply a sufficiency of the vitamin frequently found in association with natural fats. The real value of fats as convenient sources of energy is obvious.

A NOTE ON THE USE OF SULFARSENOL IN THE TREATMENT OF CONGENITAL SYPHILIS.

BY E. CRAWFORD, M.B., CH.B. GLASG.,

AND

G. B. FLEMING, M.B.E., M.D. CAMB.

(*From the Royal Hospital for Sick Children, Glasgow.*)

MOST workers will admit that salvarsan or one of its allies along with mercury is the treatment par excellence for all manifestations of syphilis, especially of congenital type. Statistics have been published of cases treated at the Royal Hospital for Sick Children, Glasgow, which show a fall in the death-rate since the advent of salvarsan.[1] In pre-salvarsan days the mortality among children under 3 months old was 71 per cent., and after the introduction of salvarsan and kharsivan it was reduced to 26 per cent. Unfortunately, in order to avoid pain or sloughing of the tissues, it has been necessary to give these preparations of arsenic intravenously, and the difficulty of such a procedure has considerably limited its use.

Recently, however, sulfarsenol—a drug which can be given intramuscularly without causing either pain or sloughing—has been put on the market, and at first it seemed to give equally good results. Attention was drawn to this fact by Dr. Leonard Findlay[2] in the discussion on congenital syphilis at the Royal Society of Medicine in February, 1921, but more extensive experience has unfortunately considerably modified this opinion. In children treated with sulfarsenol the manifestations of the disease quickly disappear if doses equal to those employed with kharsivan (0·12 to 0·2 g.) are given, and the general condition of the children improves remarkably; but if the crucial test, the Wassermann reaction (W.R.) is employed, then the results do not compare at all favourably with those obtained earlier with kharsivan and neokharsivan.

For example, 35 children have now been treated with intramuscular injections of sulfarsenol and mercurial inunction. In order to compare the results with those published for kharsivan the children have been divided into two groups: (1) children under 1 year of age; and (2) children over 1 year of age.

As is shown in the table (Group I.), 19 children received from 7 to 9 injections and a negative Wassermann reaction was obtained in 8, or 42 per cent. Four children received from 10 to 18 injections and in one a negative W.R. was obtained. Thus in 9 of the 23 children under 1 year of age—i.e., in 39 per cent., a negative W.R. was obtained, but in 14, or 60 per cent., it remained positive after from 7 to 18 injections had been given. The figures given by Dr. Findlay for kharsivan indicate much better results. A negative W.R. was obtained in 64 per cent. of his cases after a course of 9 or fewer injections.

GROUP I.—*Children Under 1 Year of Age (23).*

No. of cases.	No. of injections.	Average No. of grammes of drug given in each case.	W.R.	
			+	–
13	7	1·06	8	5
4	8	1·05	2	2
2	9	1·41	1	1
1	10	1·42	1	—
1	12	2·04	—	1
1	15	2·76	1	—
1	18	1·95	1	—
Total 23	—	—	14	9
GROUP II.—*Children Over 1 Year of Age (12).*				
1	3	0·72	1	—
1	4	1·92	1	—
1	5	2·40	1	—
1	6	1·44	1	—
5	7	1·48	5	—
1	12	3·12	1	—
2	15	5·92	2	—
Total 12	—	—	12	—

In Group II., of 12 children over 1 year old (five of whom had previously been treated with neokharsivan) none gave a negative W.R. after from 3 to 15 injections of sulfarsenol, whereas among Dr. Findlay's cases over 1 year old treated with intravenous neokharsivan a negative W.R. was obtained in 50 per cent. Among the 35 children treated with sulfarsenol and mercury only one death occurred, and it was due to bronchopneumonia.

These results suggest that the intramuscular injection of sulfarsenol is not as efficacious in producing a cure of congenital syphilis, as evidenced by the W.R., as intravenous injection of kharsivan. Whether the virtue in the latter method lies in the drug per se or in the method of administration (intravenous as against intramuscular) we are at present unable to say. On the other hand, the work of Harrison, White, and Mills[3] seems to show that intramuscular injection of neosalvarsan or its substitutes is more efficacious in producing a negative W.R. than intravenous injection of these drugs. In these cases, however, a very much larger dose was given intramuscularly than intravenously, and they did not attempt to determine the relative efficacy of the various arsenical preparations they used.

---

* Since this was written the animals in both groups have reproduced, and several healthy normal litters of young have been reared by the females on the fat-free diet, as well as by those on the more normally-balanced ration.

of the associated vitamin, and therefore the results obtained are not free from complications which arise from this cause.

The absence of the vitamin A from the diet of animals induces an abnormal condition which may be recognised by certain symptoms, and in the paper referred to above it was shown that there was no appreciable difference in the type of symptoms, or in the time which elapsed before they appeared, in groups of animals fed on diets deficient in this vitamin with or without true fats. This was taken as indicating that true fats may be dispensable components of the mammalian diet provided that a sufficient supply of calories is given in other forms. The next step was obviously to attempt to feed animals on diets which would supply the requisite amount of the accessory vitamin, but which were devoid of free fats. Experiments on these lines, however, demanded that a natural source of the vitamin A containing no fat should be discovered, or that a method of separating the growth-promoting substance from the fats in which it naturally occurs should be found.

Conclusions Drawn from Preliminary Work.

During the last two years attempts have been made by us to accomplish both these tasks. In a former preliminary communication before the Physiological Society (1920) it was shown that by employing an extract prepared from carrots it was possible to supply the vitamin in a palatable form without, at the same time, giving more than minute traces of glycerides. Experiments were made with this preparation, and it was found that young rats will live and show growth for several months on diets freed from all but very small traces of fat. Allowing for the small amount of fat in the extract from carrots it was estimated that the animals received about 14 mg. of true fats per day in an average ration of 15–20 g.

The results were, however, regarded as preliminary, partly because normal growth was not obtained, and also because a certain amount of true fat was being given. The conclusions drawn from the results were summed up in the following statement:—

> "Unless this minute amount of fat plays as important a rôle in the metabolism of the organism as do the minute quantities of such substances as the accessory factors, it is reasonable to suggest that pure fats are dispensable constituents of the mammalian diet."

Since this work was carried out we have devoted further attention to this question, and as we have now succeeded in separating the vitamin from every trace of true fats we have at last been able to study the problem adequately. It is interesting to note that very shortly after the preliminary results were published by Drummond some very similar experiments were described by Osborne and Mendel (1920), who obtained good growth on diets containing mere traces of true fats and whose conclusions were almost identical with our own; "if true fats are essential for nutrition during growth the minimum necessary must be exceedingly small."

The Separation of Vitamin A from Fat.

McCollum and Davis (1914) first stated that the vitamin found in butter fat would resist saponification processes applied to the fat, but this observation was not confirmed by Drummond. More recently, however, it has again been asserted by Steenbock and Boutwell (1920) that a fraction from the unsaponifiable matter of certain oils contains the vitamin. When this latter paper appeared we had ourselves just completed another study of the question, and had found that the negative result previously reported by Drummond was probably due to destruction of the active substance by contact with air, and that if such contact is prevented the activity passes into the unsaponifiable fraction of the fat. We have found it possible to prepare extracts of extraordinary potency from fish liver oils and from green plant tissues by this means, of which a fuller account will be given later.

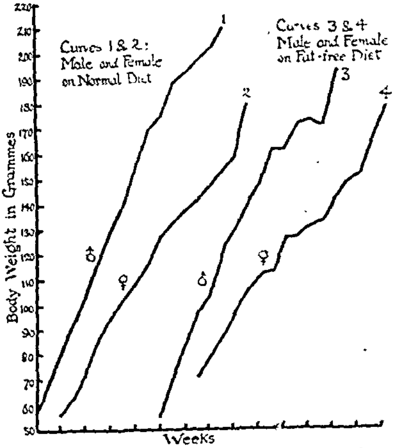
The possession of such material made it possible at last to test satisfactorily the problem of the dispensability of fat, since it was practicable to compound an artificial diet supplying all the known dietary essentials but devoid of neutral fats. The preparation of the constituents of the diet was the subject of great care. The protein (caseinogen) and the starch were rendered as free from fat as is possible by repeated and prolonged extraction with hot alcohol and ether, and so far as we are aware the only chance of the diets containing any trace of fat was from the inclusion of yeast extract as a source of the vitamin B. The ether extract of this product was, however, found to be almost negligible—0·08 per cent.—of which less than half was true fat.

Feeding Experiments.

The composition of the two dietaries used by us was as follows:—

	Normal diet.	Fat-free diet.
Caseinogen	20	20
Starch	50	65
Purified fat (tristearin)	15	0
Yeast extract	5	5
Lemon juice	5	5
Unsaponifiable matter from fish liver oil	0·02–0·04 g.	0·02–0·04 g. per day
Mixture of salts	5	5

The two dietaries were given daily in the form of food pastes made up with water, except for the unsaponifiable matter, which was given as a daily supplement, as is our custom. Young rats as soon as weaned were placed in groups on these two rations and have been under close observation ever since. The experiments have now been running for several months and the progress of the two groups has been parallel, apart from the fact that the few deaths which have occurred were of animals on the fat-free diet. The food consumption of both groups has throughout been good, and no abnormality has as yet arisen which could be attributed to the absence of fats. Naturally the group on the fat-free diet consumes a larger amount of food daily, since this is necessary to ensure the requisite calorific intake.



Growth curves of young rats fed on a normal diet (1 and 2) and a fat-free diet (3 and 4).

Animals from each group have from time to time been killed and submitted to post-mortem examination, but without any abnormality being detected. The amount of body fat in those on the fat-free rations was normal. Several animals in both groups have

14·9 and a maximum of 262·0 mg. per kilo. of dry tumour. This variation cannot be correlated with any distinct differences in the nature of the tumours, except that those which are most degenerated tend to show a larger amount of copper. For instance, Nos. 1, 4, 9, 10 (mean Cu = 177·0) showed a considerable amount of degeneration, while Nos. 2, 6, 12, 15, 16, 17 (mean Cu = 32·5) showed very little. Nos. 20 and 21 were from different portions of the same fibroid (total weight over 18 lb.) and Nos. 32 and 33 were from corresponding portions of the uterine wall in the same case. The two specimens of the tumour and the two portions of the uterine wall show somewhat similar differences in Cu content. The two specimens of dermoid cyst contents, Nos. 23 and 24, were from different portions of the same cyst, No. 23 being from a hæmorrhagic area and No. 24 from an area which was largely necrotic and contained a large excess of calcium. This necrotic area contained a large amount of copper.

In the specimens of alimentary canal the most striking feature is the large amount (501) in the mucous membrane of the rectum. This was taken just above a carcinoma (No. 5) and there was a very small amount available, so that there is probably a large error. The amount of copper, however, must have been great to enable it to have been estimated at all. Possibly the copper is excreted by the large intestine, as is calcium.

The ten specimens of liver examined show with one exception (No. 34) less variation than the tumours or the alimentary canal. The kidneys show practically the same average amount as the liver. Here again there is one specimen (No. 49) with a content very much higher than the rest, and this is not from the same case as the liver with the high content (No. 34). The spleens again show one specimen with a high content (No. 52) from the same case as liver No. 34.

of the associated vitamin, and therefore the results obtained are not free from complications which arise from this cause.

The absence of the vitamin A from the diet of animals induces an abnormal condition which may be recognised by certain symptoms, and in the paper referred to above it was shown that there was no appreciable difference in the type of symptoms, or in the time which elapsed before they appeared, in groups of animals fed on diets deficient in this vitamin with or without true fats. This was taken as indicating that true fats may be dispensable components of the mammalian diet provided that a sufficient supply of calories is given in other forms. The next step was obviously to attempt to feed animals on diets which would supply the requisite amount of the accessory vitamin, but which were devoid of free fats. Experiments on these lines, however, demanded that a natural source of the vitamin A containing no fat should be discovered, or that a method of separating the growth-promoting substance from the fats in which it naturally occurs should be found.

Conclusions Drawn from Preliminary Work.

During the last two years attempts have been made by us to accomplish both these tasks. In a former preliminary communication before the Physiological Society (1920) it was shown that by employing an extract prepared from carrots it was possible to supply the vitamin in a palatable form without, at the same time, giving more than minute traces of glycerides. Experiments were made with this preparation, and it was found that young rats will live and show growth for several months on diets freed from all but very small traces of fat. Allowing for the small amount of fat in the extract from carrots it was estimated that the animals received about 14 mg. of true fats per day in an average ration of 15–20 g.

The results were, however, regarded as preliminary, partly because normal growth was not obtained, and also because a certain amount of true fat was being given. The conclusions drawn from the results were summed up in the following statement:—

> "Unless this minute amount of fat plays as important a rôle in the metabolism of the organism as do the minute quantities of such substances as the accessory factors, it is reasonable to suggest that pure fats are dispensable constituents of the mammalian diet."

Since this work was carried out we have devoted further attention to this question, and as we have now succeeded in separating the vitamin from every trace of true fats we have at last been able to study the problem adequately. It is interesting to note that very shortly after the preliminary results were published by Drummond some very similar experiments were described by Osborne and Mendel (1920), who obtained good growth on diets containing mere traces of true fats and whose conclusions were almost identical with our own; "if true fats are essential for nutrition during growth the minimum necessary must be exceedingly small."

The Separation of Vitamin A from Fat.

McCollum and Davis (1914) first stated that the vitamin found in butter fat would resist saponification processes applied to the fat, but this observation was not confirmed by Drummond. More recently, however, it has again been asserted by Steenbock and Boutwell (1920) that a fraction from the unsaponifiable matter of certain oils contains the vitamin. When this latter paper appeared we had ourselves just completed another study of the question, and had found that the negative result previously reported by Drummond was probably due to destruction of the active substance by contact with air, and that if such contact is prevented the activity passes into the unsaponifiable fraction of the fat. We have found it possible to prepare extracts of extraordinary potency from fish liver oils and from green plant tissues by this means, of which a fuller account will be given later.

The possession of such material made it possible at last to test satisfactorily the problem of the dispensability of fat, since it was practicable to compound an artificial diet supplying all the known dietary essentials but devoid of neutral fats. The preparation of the constituents of the diet was the subject of great care. The protein (caseinogen) and the starch were rendered as free from fat as is possible by repeated and prolonged extraction with hot alcohol and ether, and so far as we are aware the only chance of the diets containing any trace of fat was from the inclusion of yeast extract as a source of the vitamin B. The ether extract of this product was, however, found to be almost negligible—0·08 per cent.—of which less than half was true fat.

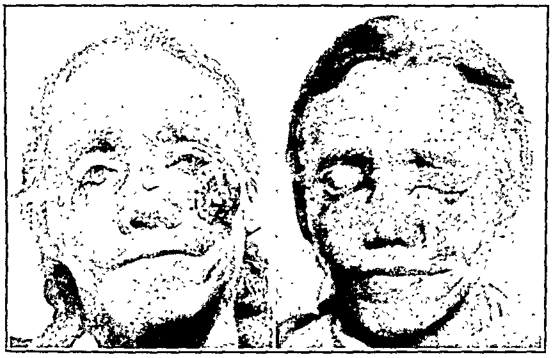
A CASE OF
LUPUS-EPITHELIOMA TREATED WITH RADIUM.

By F. Joselin Jauch, M.R.C.S., L.R.C.P. Lond.,
RESIDENT MEDICAL OFFICER, HOSPITAL OF ST. JOHN AND ST. ELIZABETH.

Lupus vulgaris sooner or later tends to heal finally, but the condition sometimes persists despite treatment. Even so, and especially if the diseased part is irritated or injured, an epithelioma may develop; the latter usually runs a rapid course owing to the good vascularisation of the tissues, and treatment is very difficult. The case described is illustrative of these points, an apparent cure being effected by the energetic use of radium.

Mrs. N. F., aged 61, was admitted to the cancer wing of the Middlesex Hospital at the beginning of November, 1920, with the following history: At the age of 6, the patient had a discharging swelling on either side of the face in the malar region, which, on treatment at various hospitals, gradually disappeared, leaving a certain amount of scarring behind. During the whole of her life, however, it appears, she was never quite free from one or two small discharging ulcers which broke down periodically. She also complained of a stiff ankle and deformed wrist, which on examination proved to be the site of an old tuberculous disease. In January, 1920, the patient accidentally scratched the diseased tissue over the left malar region with a comb. Subsequently an ulcer formed at the site of injury, which was treated with a "burning liquid." The edge of the ulcer began to grow, and its increase was accompanied by shooting pains radiating to the top of the head, and a copious offensive discharge. The growth encroached upon the left eye, giving rise to a great deal of pain here. She had been admitted to a surgical ward in September, 1920, but was discharged as the condition had progressed too far for operation.



Before treatment with radium. After treatment.

On examination, the patient's general condition was rather poor; the bridge of the nose was very depressed, and covered, as were both cheeks, with papillomatous elevations of lupus, the scarring of which had caused ectropion of the lower eyelids, especially of the right. On the left malar and temporal region was an oval mass of growth, 1½ in. by 2½ in., ulcerating in the centre, firmly fixed to the subjacent structures, with hard raised edges and an irregular surface, and having a copious and offensive discharge. It encroached upon the orbital cavity, displacing the eye backwards and inwards, having destroyed a considerable portion of the lower eyelid by its growth. The eye was subject to fairly marked conjunctivitis, and vision was very poor on this side. The diagnosis of lupus-epithelioma was made and confirmed histologically. No enlarged glands were palpable. The Wassermann reaction was negative.

The treatment was commenced on Nov. 13th, 1920, and consisted in the application of 1 mm. screened radium in tubes, applied to the surface and periphery of the growth, with a rubber protective between the two; the latter, however, was later discarded. The first dose consisted of 284 mg. of radium applied for 10 hours. The amount and time of exposure, however, were later increased, as I found that the radium in smaller quantities stimulated the growth to further activity. Necrosis of the growth took place after six weeks' treatment, the slough separating on Jan. 7th, 1921, and local recurrences were dealt with by further applications of both screened and unscreened radium, in all 12 323 mg.-hours of radium. The pain gradually lessened and practically disappeared. Unfortunately, it was found necessary to remove the left eye on account of panophthalmitis on Feb. 14th. On the 28th the papillomatous elevations on the nose and cheeks had completely disappeared and the epithelioma had been replaced by healthy granulations; when the patient was seen in April there was no evidence of a recurrence, though the area was subject to lymphatic œdema.

For permission to publish this case I am indebted to Mr. W. Sampson Handley, surgeon to the Middlesex Hospital, under whose care the case was admitted.

A CASE OF
LABIO-GLOSSO-LARYNGEAL PARALYSIS
SUCCESSFULLY TREATED BY VACCINE.

By J. C. Voigt, M.D. Edin.

The rarity of this disease, and the fact that practically all authorities on labio-glosso-laryngeal paralysis are agreed in describing its causes as unknown, and its prognosis as hopeless, give interest to the following case.

At Easter, 1920, a lady, who, during 30 years has been a patient of mine whenever she was resident in Southport, and attended by Dr. L. D. Temple of Rock Ferry when she lived in that district, came to see me complaining of bronchitis and nasal catarrh. The "cold" from which she was suffering appeared to me of the mild influenza type—if influenza can ever be described as mild. When she was breathing in, I noticed a peculiar occasional sound, half-wheezing, half-sighing, sometimes followed by a rasping clearing of the throat.

I saw the patient again on Sept. 15th, at her home in Birkenhead, where she had been under the care of Dr. Temple since the early part of August. The first symptom had been a difficulty in swallowing, then dribbling of saliva from her mouth, difficulty in articulation of linguals and labials, and inability to blow her nose, which felt "closed up." These symptoms had become progressively worse, until when I saw her with Dr. Temple, on the 15th, a continuous stream of saliva was running from her mouth, and she had constantly to dry her lips with wool. She could only swallow liquid food, and that with difficulty; her speech was very indistinct.

We agreed that since extensive pyorrhœa alveolaris complicated an apparent acute case of labio-glosso-laryngeal paralysis in which the œsophageal muscles were failing in sympathy with those of the larynx, skilful nursing was a first necessity. Circumstances did not permit the patient's removal to a nursing home; so after seven weeks in the Royal Infirmary, Liverpool, she was placed under my care in Southport.

What struck me as most noticeable now was her mental depression and apathy. She could swallow soft foods better than liquids; but the dribbling of saliva from her mouth was worse and her speech was very difficult to follow. Her pulse was small and frequent. Her senses of taste and smell were both affected, and these facts, together with a history of four definite attacks of influenza, led me to resolve to try a treatment of vaccine of *B. influenzæ* (with pneumococcus for prophylaxis). On account of the myocardial weakness, I put her on full doses of liquid extract of fresh green kola nut with Peruvian bark and glycerine. To correct intestinal stasis she had 3½ gr. of phenolphthalein nightly, and during the first week 1/60 gr. strych.-sulph. hypodermically every day. I determined to attempt an improvement with blended vaccines, and on Dec. 1st she was given hypodermically a vaccine injection of:—

B. influenzæ	..100 million.	*Staph. aureus* ..	30 million.

COPPER IN TUMOURS AND IN NORMAL TISSUES.

BY CHARLES POWELL WHITE, M.A., M.D.CAMB., F.R.C.S. ENG.

(*From the Helen Swindells Research Laboratory, University of Manchester.*)

DURING an investigation of the amount of phosphorus and calcium in tumours it was noticed that on evaporating to dryness an acid extract of a carcinoma and igniting the residue, the ash was distinctly of a blue colour. This colour was easily shown to be due to the presence of copper. I proceeded therefore to examine other tumours and normal tissues for the presence of copper, and to estimate the amount present. The method of treating the material was, briefly, to extract the dried tissue successively with boiling $CHCl_3$ and warm 1 per cent. HCl. The acid solution was used for the estimation. Examination of the insoluble residue in several cases did not show the presence of any copper.

The estimation was eventually carried out by a colorimetric method, using a Dubosc colorimeter. The delicate colour tests for copper are:—

1. The brown colour formed on evaporating to dryness a solution containing bromide of copper. This is probably the most delicate test for copper, but is not easily adapted for quantitative work. It was noticed in every case during the preparation of the material.
2. The purple colour formed on adding a solution of formaldoxime to a solution containing copper. This is a very delicate test, but the colour is apt to change and it is not therefore adapted for use in a colorimeter.
3. The red colour produced by adding a copper salt or metallic copper to a solution of a morphine salt containing H_2O_2 and NH_3. This test for morphine was discovered by Dr. T. H. Oliver (1914[14]) working in my laboratory, but a similar test had previously been described by Denigés. It will detect 0·01 mg. of copper in about 10 c.cm. of solution, but the test is not adapted for colorimetric work as the depth of colour is not proportionate to the amount of copper and the colour is not permanent.
4. The pink colour of cupric ferrocyanide. This is useful for colorimetric work, but there are difficulties in its use which will be described below. It was used to a large extent.
5. The brown colour of cuprous sulphide. This also was used.
6. The blue colour of ammonio-cupric solutions. This was noticed in each case during the preparation of the material, but is not of sufficient delicacy for the present investigation.

Two main difficulties were experienced in using the ferrocyanide test. First, in the solution to be tested the cupric ferrocyanide tended to separate out as a precipitate, instead of remaining in colloidal solution as it did in the standard solution. This difficulty was partly overcome by the addition of a little gum arabic, but it remained a difficulty and in some cases prevented an accurate comparison. The other difficulty was that the pink colour in the solution to be tested often diminished or disappeared in a short time. This disappearance was shown to be due to the oxidation of the ferrocyanide to ferricyanide, but the cause of this oxidation was not detected. It did not occur in the standard solution. This difficulty was overcome by the addition of a reducing substance. Glucose and formalin were tried, but their action was too slow. Phenylhydrazine hydrochloride (1 per cent.) was immediately successful and was frequently used, and eventually a saturated (4 per cent.) solution of hydrazine sulphate was used as being a cleaner substance to work with than the phenylhydrazine hydrochloride. Lehmann (1897[12]) also met with this difficulty and traced it to the presence of HNO_2. He overcame it by the addition of urea.

Owing to these difficulties with the ferrocyanide test the later estimations were made with the sulphide. Comparisons between the two methods showed that they gave the same results, being of about the same order of delicacy, an amount of 0·1 mg. in 15 c.cm. of solution giving a sufficient colour for comparison.

Details of Method.

The method in detail was as follows:—

The acid (1 per cent. HCl) extract of the tumour or other tissue having been evaporated down to known volume, usually 100 or 200 c.cm., a definite amount—25, 50, or 100 c.cm.—was taken and evaporated to dryness in a silica dish, the residue being ignited. The ash was dissolved in dilute HCl and the copper precipitated with H_2S. The precipitated sulphide was dissolved in bromine water, and the filtered solution evaporated to dryness on a waterbath, a little H_2SO_4 (0·5 c.cm. of N/2 solution) being added before drying. The residue was dissolved in a little water and a drop of $FeCl_3$ solution added, and then excess of NH_3. The solution was filtered from the precipitate of $Fe(OH)_3$ and the filtrate again evaporated to dryness with the addition of a little H_2SO_4 before drying. The residue was then ready for estimation. The two methods employed were as follows:—

A. The residue was dissolved in a little water and filtered. One c.cm. of 1 per cent. potassium ferrocyanide, 1 c.cm. of saturated hydrazine sulphate (or of 1 per cent phenylhydrazine hydrochloride), and a little gum arabic added, the whole being made up to known volume, usually 15 c.cm.

B. The residue was dissolved in a known volume of water and the solution saturated with H_2S.

The standard solution contained one part Cu in 10,000 of water and was prepared by dissolving the equivalent quantity of $CuSO_4\,5H_2O$ in water. It was tested against a solution prepared by dissolving 1 g. of electrolytic copper in HNO_3 and diluting to 5000 c.cm. One to five c.cm. of the standard solution were used for each test, the same reagents being added as to the solution to be tested, and the whole made up to known volume with water. It is convenient but not necessary to make the standard solution up to the same volume as the solution to be tested. The two solutions are then introduced into the receptacles of the colorimeter and a series of readings (usually 15 or more) taken, the mean of the series being taken as the result.

All reagents used, and the air of the laboratory, were tested for the presence of copper with negative results, except in the case of the hot water supplied to the laboratory. This contained a fraction of a milligramme per litre. This hot water, however, was not used except occasionally for washing apparatus. The method of estimation proved very accurate when tested with different known solutions of copper. As a test for the method in the presence of organic matter 5 c.cm. of the standard solution (0·5 mg. Cu) were added to 1600 c.cm. of urine. A subsequent estimation after evaporating to dryness, &c., gave 0·55 mg. Cu (and urine itself may contain copper). In another test in which 0·2 mg. Cu were added to 500 c.cm. of urine the amount found was 0·21 mg.

One possible source of fallacy when the sulphide method is used is the possible occurrence of lead. Most of the lead would be removed in the process (by H_2SO_4 and NH_3) but traces might survive, as it appears almost impossible to separate the last traces of lead from copper. An experiment was carried out in which 5 c.cm. of the standard solution and a considerable amount of lead acetate were added to 500 c.cm. of urine. The result was an apparent excess of Cu in the final estimation to the extent of 0·06 mg. (0·56 instead of 0·50), and this excess may have been due to the copper in the urine. There was, however, no reason to suppose that any of the material examined contained lead. This source of fallacy does not occur in the ferrocyanide method, but in the latter especial care must be taken to remove the last traces of Fe.

Results.

Coming now to the results, every specimen examined (over 100 in all) contained copper with the exception of one specimen of urine and one sample of egg white (No. 78). In this latter case the eggs had been boiled hard before drying, and the albumin dried into a very hard horny mass which yielded little to the acid solution. Examination of the insoluble residue in this case showed the presence of traces of copper. The negative results in these cases tend to confirm the general reliability of the method.

The results are given in the table expressed as milligrammes Cu per kilo. of the fresh or dry weight. They show that copper is present in tissues to a greater extent than is usually supposed. As a general rule there was not a sufficient amount of material to allow of a repetition of the estimation but, where possible, this was done. Some of these duplicate estimations are given in Table I.—e.g., No. 21.

The 21 specimens of tumours examined show a great variation in Cu content, with a minimum of

Reviews and Notices of Books.

DISEASES OF THE NEW-BORN.

By Dr. AUGUST RITTER VON REUSS, Director of the Department for the New-Born at the First University Women's Clinic in Vienna. London: John Bale, Sons and Danielsson, Ltd. 1921. With 90 illustrations. 52*s.* 6*d.*

THIS book was published in Vienna in 1914 and we owe the war, therefore, a still further grudge for the delay of seven years before the translation reaches this country. Without doubt it is a book of great importance, which deals more thoroughly with the subject of the new-born than any we can call to mind. Only two points suggest criticism. The first is that the title does not suggest at all adequately how much the book contains of value and interest to the general practitioner. It should, we agree, be read as a matter of course by every one who already has a special interest in obstetrics or pædiatrics. But the title will not do much to encourage its circulation beyond that point. This is unfortunate, for the author takes a wide view of his subject, and the book contains a valuable section on the physiology of the new-born, an equally good one on breast nursing, while the premature child and its needs are ably discussed before the subject suggested by the title is reached. There follows an account of birth injuries, of diseases of individual organs and systems, and of congenital malformations. The hæmorrhagic diseases are fully treated, and the chapters on acute and chronic infections are good.

The second and more material complaint arises out of the extreme anxiety of Dr. von Reuss to acknowledge throughout the text every authority with whose writings his industry has brought him into contact. There is a bibliography at the end of the book wherein some 1800 publications are mentioned and this is all to the good. But the tiresome honesty which sees fit to load almost every sentence with a host of names is utterly ruinous to literary style. It may be considered captious to criticise a habit, the lack of which we often condemn in French writers, but in a text-book of this type some collect in acknowledgment of sources of erudition at the end of each chapter would make the volume much more readable. There are passages in this book which read like a Parliamentary division list. Why should it be thought necessary, in a short sentence on infections of the salivary glands, to state that Messrs. Hennig, Mikulicz, and Kümmel differ in their views from Messrs. Nobécourt-Hutinel, Hofstaelter, Auerbach, and Bretschneider? And in the next sentence there are inflicted on the reader the names of the bacteriologists who have isolated different organisms in this complaint. Perhaps, too, irritation is somewhat increased by the rarity of an English name. In the whole bibliography there seem to be only about 40, and of these about half are American. Dr. von Reuss might reply, one fears with some truth, that there are not a great number more who could serve his purpose.

One turns with relief from many of the author's introductions to reach his summaries of evidence. For these are clear, well written, and convincing. Certainly one feature of this book, and one of the most valuable, would be hard to seek in any English or American study of infancy, even one concerned with the new-born. This is the section on lactation and breast nursing. There are here 61 pages devoted to breast feeding and the conquest of its difficulties, and but four to artificial feeding. Space in an exactly opposite proportion is usually allotted to these aspects of the subject in our text-books. Where else could be found so stimulating a confession as "Our experience concerning the artificial feeding of new-born children is somewhat scanty . . . . with regard to artificial feeding in the first week we know exceedingly little." We fear to think of the fate of medical student or pupil midwife in 1914 in this country who reached a final examination in this condition of praiseworthy ignorance. Yet Dr. von Reuss was specially appointed to teach midwives in the obstetric clinic in Vienna on the feeding of infants.

The English edition has been prepared under the supervision of Dr. J. D. Rolleston, who has revised the translation. This is throughout exceedingly well done. The illustrations are good, and we hope a new edition may contain many more. The book is a mine of information.

Physiologie normale et pathologique du Nourrisson. By E. LESNÉ and LÉON BINET. Paris: Masson et Cie. 1921. Pp. 297. Fr.18.

THIS volume, which is the joint work of a physiologist and of a clinician, embodies a summary of the facts known as to the general physiology of the infant in health and disease, forming what is practically a monograph on the subject. Although reference is made to the work of more than 700 authors—including, however, very few English names—the volume consists largely of the results of personal researches undertaken by MM. Lesné and Binet themselves.

In an introductory chapter the authors point out that while the anatomist and the pædiatrist have studied the new-born infant each from his own point of view, the physiology of the suckling has hitherto received no such specialised attention, the present volume being an attempt to supply the lack. The 17 chapters deal with the blood; the circulatory, muscular, nervous, genital and urinary systems; respiration, digestion, and nutrition; thermometry and calorimetry; growth, muscular movement and the special senses; and the means of defence possessed by the organism. It will be seen that the range of subjects is very wide, and the authors having correlated with these studies various pathological considerations, the book is one that will appeal with some force to the general practitioner. Certain controversial statements appear. Among the many contra-indications to suckling given are included all organic affections of the nervous system as well as most of the neuroses, while, on the other hand, erysipelas in the mother, which von Reuss considers an absolute contra-indication owing to the high susceptibility to it of the infant, is not here regarded as a bar. In discussing the question of the transmission of tuberculosis by cows' milk it is stated that even sterilised milk from tuberculous cows will, owing to its content of dead tubercle bacilli, cause cachexia and death in a young animal; while a further statement in the same section that the question of the identity of the bovine and the human tubercle bacillus is still sub judice will not be endorsed by all bacteriologists. An index would add materially to the value of the book. These, however, are minor blemishes in a work of unusual merit and completeness, in which the whole subject is handled with a scientific knowledge and thoroughness entitling the volume to a place in every medical library.

HYPNOTISM AND SUGGESTION.

Treatment by Hypnotism and Suggestion, or Psychotherapeutics. Seventh edition. By C. LLOYD TUCKEY, M.D. Aberd. With a Chapter on Treatment by Suggestion during the War, by A. PERCY ALLAN, M.D., B.S. Lond. London: Baillière, Tindall and Cox. 1921. Pp. 413. 21*s.*

Dr. Lloyd Tuckey's well-known volume on treatment by hypnotism and suggestion appears in a seventh edition, proof of its continued usefulness over more than 30 years and of the fact that psychotherapy needs no stimulus from war experience to justify its worth in clinical medicine. There are, of course, other forms of psychotherapeutic treatment than hypnotism and suggestion, and though the chapter formerly contributed by Dr. Constance Long and dealing with psychoanalysis is now omitted, this is not because of the author's lack of sympathy with the latter but solely

The average amount of copper in the spleen is higher than that in the liver or kidney. The ribs show a uniformly high copper content (189.8). The large amount in No. 74 is probably an error. A second estimation showed a very much smaller amount, but there was not sufficient material to allow of a third estimation.

The last part of the table shows the copper content of various substances for comparison. An interesting point is the high content of egg shells and the closely similar content of oyster shells. Possibly the copper may be concerned in the shell pigments. Another interesting point is the similarity of the three seeds nux vomica, cardamoms, and oats. In the case of the rabbits and mice the material examined was the acid extract of the whole animal. In the three specimens of normal urine about two litres was used each time. Since this work was done I have found copper in nine other specimens of normal and nephritic urines.

Recorded Estimates of Copper in Tissues of Vertebrates.

Few estimates of the amount of copper in the tissues of vertebrates have been recorded. I have not had access to the original communication by K. B. Lehmann (1895[11]) but his figures are partially quoted in Oppenheimer's "Handbuch" and also by Yagi (1910[16]). Comparing the figures for the liver and kidney (human) with my own expressed as milligrammes per kilo. of fresh weight, we have—

	Lehmann	Yagi	White
Liver	3.75	11.52	12.0
Kidney	1.73	3.21	13.5

It will be seen that as regards the liver my figure agrees very well with that of Yagi and both are considerably higher than that of Lehmann. I have found much more copper in the kidneys than either of the other two observers. Yagi suggests that the reason why his figures are higher than those of Lehmann is to be found in the more extensive use of copper cooking vessels by the Japanese. My figure for oysters (96.1 mg. per kilo. fresh) agrees exactly with that found by Dubois (1900[7]), which was 96.5.

Possible Significance of Copper Content of Tumours.

As this investigation was mainly of a preliminary nature directed towards finding out whether the copper content of tumours differed from that of other tissues and how widely copper was distributed in the organism no definite conclusions can be drawn as to the significance of the presence of copper in the higher animals. While it has been known for a long time that copper plays an important physiological rôle in some of the invertebrata, especially molluscs and arthropoda, its presence in the higher animals has usually been regarded as an accident, and of no physiological importance except that it enters into the formation of the pigment turacin of birds' feathers, in which copper exists in combination with hæmatoporphyrin (Laidlaw, 1904[10]). Similarly, its presence in plants is attributed to accident and in pharmaceutical preparations it has been attributed to the use of copper vessels in manufacture. It is possible, however, that copper may have a physiological action as a catalyser. In the morphine reaction described above Oliver (1914[14]) found that during the reaction the morphine is destroyed by oxidation and cannot be again recovered. He also determined in the course of further investigations (unpublished) that copper salts give the reactions which are usually relied on to detect the presence of oxidases (guaiac and indophenol reactions).

The presence of an increased amount of copper in degenerated tumours suggests either that the degeneration is associated with an increased catalytic action due to the increased amount of copper, or it may be that copper like calcium tends to be deposited in degenerated areas. The question whether or not copper is of physiological importance in the higher animals and plants must thus be left for future investigation. The universal distribution of copper and its presence in seeds, eggs, and fœtal tissues as well as in adult organisms would seem to point to its being something more than an accident. In man it has been found in fœtal as well as in adult livers (Bergeson and d'Hôte, 1875[1]) and, indeed, in larger quantities in the fœtal organ than in the adult (v. Italie and v. Eck, 1913[9]).

Distribution of Copper in Animal and Vegetable Organisms.

As copper is present in wild animals and in animal and vegetable foodstuffs its presence in man cannot be attributed wholly to the use of copper vessels, &c. The distribution of copper in the animal and vegetable kingdoms appears to be universal, so far as it has been looked for. According to the above investigations it is present in man, cattle, sheep, fowls, rabbits, and mice, and also in oats, nux vomica, cardamoms, and bread. It has also been described in fish (Dubois, 1900[7]), whales (Dougal, 1911[6]), dogs, cats, horses, swine (Lehmann, 1895[11]), in numerous plants—e.g., belladonna, colchicum, ergot, digitalis, sarsaparilla, thuja, oats, cardamoms, wheat, buckwheat—and in pharmaceutical preparations (Lehmann, Lewis, 1914[13], and others). In the lower animals in which it exists for the most part as entering into the composition of a respiratory pigment, it is present in cœlenterata, echinoderms, crustacea, molluscs, insects, &c. (Dubois, 1900[7]). It has also been found in the eggs of some of these—e.g., sepia (Dhéré, 1900,[3] 1904[4]) and lobsters (Dougal, 1911[5]).

Another metal which appears to be universally present in the animal and vegetable kingdoms is manganese. The presence of this metal has been studied especially by Bertrand, who with Medigreceanu (1912[2]) examined 150 specimens from 15 species of vertebrates and found manganese present in all except in the white of birds' eggs. Bertrand is of the opinion, based on experiments on aspergillus and other organisms, that manganese is of considerable physiological importance. In my material I tested for manganese in 24 cases taken at random (including seven tumours) and found it present in all, but I did not estimate the amount.

Summary.

1. Copper appears to be universally present in the tissues of animals and plants so far as it has been looked for.

2. The known catalytic action of copper and the presence of copper in seeds, eggs, and in fœtal as well as in adult tissues, suggest that it has a physiological significance.

3. Copper is present to a greater extent in degenerating tumours than in those which are not degenerated.

This work was carried out in connexion with the Christie Hospital, Manchester, and the Pilkington Cancer Research Fund.

LITERARY INTELLIGENCE.—Messrs. E. and S. Livingstone have undertaken the British and Colonial Agency of the American *Medical Record* and will send specimen copies to intending subscribers. Annual subscription, including postage, is 35s., and should be sent to 17, Teviot-place, Edinburgh.

PRESENTATION TO A MEDICAL MAN.—Dr. T. Glyn James, of Pontypool, has been presented with a cheque for 100 guineas by the workmen of the Pontnewynydd Sheet Galvanising Works in recognition of his work as President of the Works Distress Fund.

A TEXT-BOOK OF PATHOLOGY.

Seventh edition. By ALFRED STENGEL, M.D., Sc.D., Professor of Medicine, University of Pennsylvania, and HERBERT FOX, M.D., Director of the Pepper Laboratory of Clinical Medicine, University of Pennsylvania. London and Philadelphia: W. B. Saunders Company. 1921. With 509 text illustrations and 15 plates. Pp. 1111. 42*s.*

WHEN this text-book first appeared in 1899 it was intended to make appeal to the "clinical pathologist" as the term was then used in America. As such, rather than as an exhaustive treatise on pathology, we then gave it favourable notice. Pathology has during the last two decades shaken itself free of many shackles, and the authors seem hardly to have kept in touch with its developments. Their present outlook on the science may be illustrated by their statement (p. 146) that inflammation "is a pathological state *per se*, but considered from the point of view of its result . . . . inflammation is essentially conservative and useful." The first seven words contain about as many misconceptions of the subject with which they are dealing as it would be possible to express so briefly. To conceive of inflammation as a state instead of a process, and by "but" to imply that pathological processes are not as a rule useful, is to go about as far astray on fundamental considerations as anyone can. It is the attitude which likes to look on the subject matter of pathology as a series of states which can be classified and labelled and put in compartments already marked out for them like a collection of postage stamps, and misses altogether the truth that the student of pathology has to do with the passing phases of a pageant of reaction and adaptation as inspiring as any that he has had a chance to get a sight of. If only the authors could have seen Burdon-Sanderson twenty-five years ago leaning up against the blackboard with his eyes shut and muttering to himself, "Yes, yes, a process, not a state"—still they have had plenty of opportunity of reading Adami. Pathology on the authors' terms is such a hopelessly dull subject—perhaps this is why they both profess medicine.

The first part, extending to 427 pages, deals with general pathology, including bacteriology, and is unsatisfactory. From the section on acidosis (p. 44) no one would gather that respiration had anything to do with the regulation of the acid-base equilibrium in the body; there is a general reluctance to make definite statements which leads the authors to surmise (p. 30) that "the low partial pressure of oxygen at high altitudes has in all probability something to do with" mountain sickness; in œdema (p. 79) "a second process at work is that known as diffusion or osmosis." It may be, of course, that the authors, by the curious convention that has prevailed and which cheap copies of Cohnheim and Lazarus-Barlow have failed to dissipate entirely, regard these functional topics as not being part of pathology properly so called and that they have dealt with them just to fill up their schedule. But sections which have been pathological for all time are equally bad. Under tumours there is no kind of attempt to discover what tumours really are, and the only recognition of the quite fundamental information which has been obtained from the experimental investigation of mouse cancers is a reference to Miss Slye's breeding experiments and (p. 168) "various investigators since Hanau have found it possible to transplant certain tumours from man to animals or from one animal to another," which could not be more misleading even if it were capable of a jesuitical defence as not being untrue. The preface is dated April, 1921, and we read that "the cultivation of the gonococcus is difficult" (p. 203), "the typhoid bacillus is peculiarly resistant and may thrive upon clothing, in soil and in water for a long time" (p. 305),—"difficult," "peculiarly," and "long" are truly relative terms—and (p. 400) that the life-history of Bilharzia after the eggs leave the body is unknown. "Dyspnœa" and "rodent ulcer" do not occur in the index, and the only reference to scurvy is (p. 368) "several micro-organisms have been described," though beri-beri and pellagra have a page apiece.

The second part, special pathology, occupies the remaining 632 effective pages. It is mostly arranged under organs, with subsections, "congenital abnormalities," "circulatory disturbances," "atrophy and degenerations," "inflammations," "infectious diseases," and "tumours," and these categories are adhered to with a remarkable determination to say something under each heading whether it be of interest or importance or not. The authors' orderly scheme requires that active and passive hyperæmia should always form subheadings of "circulatory disturbances," and they tell the student that the former is associated with the early stages of inflammation and the latter with general circulatory failure over and over again under each organ separately; what is true of the pharynx, œsophagus, and kidney is probably true of the stomach, intestines, and pancreas; in all about a page is wasted by repeating for each of these six organs what a tolerable acquaintance with general pathology should make it unnecessary to state for any of them. The whole forms a dull and uninspiring catalogue of reasonably accurate information.

The book propagates the idea that pathology deals with a series of isolated anatomical facts with no general principles behind them and without any very important functional effects. The pity of the situation is that since 1898 it has gone through seven editions and has been reprinted in all on 18 occasions without keeping in touch with the science of pathology. The get-up of the present edition is excellent, the illustrations variable, some very good with a few quaint relics—e.g., the picture of acute urethritis (Fig. 398); a fair number are clinical without pathological interest.

MOTHER AND CHILD.

Fourth edition. By EDWARD P. DAVIS, A.M., M.D. London: J. B. Lippincott Company. 1921. Pp. 278. 12*s.* 6*d.*

THIS book, the first edition of which was brought out in 1902, is intended rather for the domestic hearth than for the medical profession. It contains nothing novel, but has been brought up to date, incorporating the more recent teaching on ante-natal care and on infant feeding. The book is in two parts, dealing respectively with mother and with child. The division of the chapters into short sections, each with its own heading, may facilitate the use of the book as a work of reference, but spoils the sequence of thought. The simple directions cover all essential points, and should result in the more intelligent observance on the part of the mother and nurse of the precautions advised by the doctor. A word may be added in praise of the illustrations, of which there are 33, more than half dealing with various details of the infant's wardrobe; these drawings add materially to the value of the book.

LE DARWINISME ET NOTRE SANTÉ.

By EDOUARD JUNG. Sainte-Marie-aux-Mines (Haute Rhin): E. and R. Cellarius. 1921. Pp. 120. Fr.5.

THIS small book is an attempt to put forward, according to the doctrines of evolution, a rational explanation of the principles underlying Nature's methods of preventing disease. It amounts to a plea for the "simple life," based upon arguments which are intended to appeal rather to the man of science than to the man in the street. After dealing with the general principles of the theory of evolution, and defining and explaining the terms in use, Mr. Jung proceeds to enunciate and consider seven laws. These lay down the relationship existing in nature between hereditary and acquired characters, and urge that some at any rate of the latter are harmful to the individual and therefore to the race. The seventh law propounds that "every (acquired) habit contrary to specific adaptations is injurious"; everything

This mixed stock vaccine was gradually increased in strength until the dose was:—

B. influenzæ	..500 million.	*Staph. aureus*	..100 million.
Pneumococcus	..200 „	Streptococcus	.. 60 „

This was at the end of January, 1921, by which time all the teeth except seven had been extracted, and there was marked general improvement. Swallowing had become easy, articulation improved, and salivation stopped. Treatment with an autogenous vaccine of *Staph. aureus* kindly made for me by Dr. T. Jorkes, Department of Pathology, St. Bartholomew's Hospital, was now commenced (first dose 100 million). The pus from which this was prepared was collected for me from the roots of freshly extracted teeth and conveyed to Dr. Jorkes by Dr. Reginald Hilton, also of St. Bartholomew's Hospital. The mixed stock vaccine was used alternately with the autogenous vaccine, and the interval following any one injection was four or five days. This was in February, and by the end of the month the patient was able to whistle and articulate perfectly, and was in fact apparently quite cured.

Up to date there has been no return of symptoms, and last month the patient increased in weight by half a stone.

Southport.

GAERTNER MENINGITIS COMPLICATING GAERTNER ENTERITIS.

By JOHN SMITH, M.B. ABERD., D.P.H.,
BACTERIOLOGIST, CITY HOSPITAL, ABERDEEN.

CASES of Gaertner enteritis complicated by development of Gaertner meningitis appear to be extremely uncommon; after an extensive search of the literature only one such case is described as having occurred. This case is mentioned by Worster-Drought and Mills Kennedy[1] in their book on cerebro-spinal fever. Records of sporadic Gaertner infections are also infrequent. Thus Savage[2] instances three cases; two recorded by Batten and Forbes (1908) occurred in infants, the chief symptoms being diarrhœa and vomiting, both terminating fatally. The third case recorded by Dean[3] (1911) occurred in an adult who had no symptoms of food poisoning, but who had a suppurative cholecystitis from which *B. enteritidis* of Gaertner was isolated. Rosher and Wilson[4] describe a fourth sporadic case which simulated typhoid fever. McNee[5] records a fifth case which was at first suspected to be a case of cerebro-spinal fever, and which later developed marked signs of pulmonary involvement. It appears, therefore, that only one case of Gaertner enteritis complicated with meningitis, and five sporadic cases of Gaertner infections, are described in the literature on this subject. Accordingly it has seemed desirable to record the following case:—

A. B., a male child, aged 5 weeks, admitted to hospital on Dec. 2nd, 1920.

History.—The child had been ill for a fortnight previous to admission. During that time the chief symptoms were diarrhœa and vomiting, with considerable pyrexia. On Dec. 1st slight head retraction was observed.

Condition on Admission.—Temp. 99·2° F., pulse 160, resp. rate 50; head retraction very marked, the anterior fontanelle bulging, and Kernig's sign present.

Course of Illness.—On the 3rd temp. rose to 101°, and from this point onwards child became progressively worse. Convulsions were frequent, and the child died on the 7th, five days after admission.

Cerebro-spinal Fluid.—Lumbar puncture was performed on admission and on four subsequent days. The first three punctures yielded a total of 110 c.cm. cerebro-spinal fluid. The fourth and fifth punctures yielded no fluid.

Bacteriological Diagnosis.—The fluid obtained at the first lumbar puncture was turbid, and when allowed to stand in a test-tube a distinct deposit was formed. The globulin tests of Noguchi and Ross-Jones showed a great increase above normal in the amount of globulin present. After standing one portion of the fluid overnight a pellicle formed. The pellicle was suspended in the centre by processes projecting from the periphery, and was very similar in appearance to that obtained in tuberculous cerebro-spinal fluids. Smears made of the deposit after centrifuging and stained by Gram's method showed the presence of numerous Gram-negative organisms, mostly extracellular. Some of the organisms were definite bacilli, others were almost coccal in shape. A differential cell count showed that 90 per cent. of the cells were polymorphs, and 10 per cent. small lymphocytes. Agar slopes and plates of trypagar,[6] containing hæmolysed blood, were inoculated and incubated overnight. On both slopes and plates numerous discrete colonies were obtained. The colonies consisted of Gram-negative bacilli.

The biochemical reactions of the organism were then investigated, and it was found that mannite, glucose, dulcite, maltose, galactose, and lævulose were fermented, while there was no change produced on lactose, saccharose, salicin, and raffinose. Litmus milk showed at first a slightly acid reaction, but later became markedly alkaline. No clot formed. Indol was not formed. The organism was motile. Agglutination tests were made, using *B. paratyphosus A*, *B. paratyphosus B*, and *B. enteritidis* of Gaertner agglutinating serums. The tubes were incubated in a water bath at 55° C. for two hours, and read after standing for quarter of an hour. It was found that the organism was agglutinated to the limit of the titre of *B. enteritidis* of Gaertner serum, and not by a dilution of $\frac{1}{100}$ *B. paratyphosus A*, and *B. paratyphosus B* agglutinating serums. Cultures were made from the fluid obtained at the second and third lumbar punctures. The same organism was present.

Post-mortem Examination.—The child showed no marked signs of wasting. The lungs were congested. Heart normal; stomach and intestines showed little macroscopic pathological change. Mesentery congested, mesenteric glands much enlarged. Liver enlarged and friable, showing marked signs of fatty degeneration. Spleen normal in appearance; kidney showed both cortex and medulla to be pale.

Pia-arachnoid, on opening of the cranium, found to be much congested. Sulcii filled with purulent exudate, most marked at base, especially left base. Superficial part of brain substance hyperæmic. Ventricles distended, containing blood-stained purulent fluid. Spinal membranes also showed an acute leptomeningitis. MacConkey plates were inoculated with material from intestinal contents, liver, spleen, and with heart blood, and pus from the brain. Typical *B. enteritidis* of Gaertner, fulfilling all the biochemical and agglutination reactions, were obtained from all these sources.

Source of Infection.—Not determined. No other cases of Gaertner enteritis were discovered in association with the case, and the five immediate contacts of the patient gave no history of any enteric infection. Samples of fæces obtained from all these contacts gave on examination for *B. enteritidis* of Gaertner negative results.

Feeding.—Previous to becoming ill the child had been fed on diluted cow's milk; after the onset of the illness a concentrated milk product had been substituted.

Conclusion.—It is evident from the clinical and bacteriological findings that this was a case primarily of Gaertner enteritis as indicated by the presence of diarrhœa and vomiting; by the isolation of the Gaertner bacillus from the intestine, liver, and spleen; and by the absence of meningeal symptoms during the first fortnight of the illness. Thereafter there was an extension of the infection to the meninges.

COLONIAL MEDICAL COUNCIL.—The South African *Union Government Gazette* announces that Dr. Arnold Hirst Watkins has been elected President of the Colonial Medical Council, with effect from August 31st, for the remainder of the period of office expiring on Dec. 31st, 1921, vice Dr. Charles F. K. Murray, resigned.

GOVERNMENT POSTS FOR WEST AFRICAN DOCTORS. We understand from *West Africa* that the Secretary of State for the Colonies has agreed to the creation of six posts in the Gold Coast Medical Service for West Africans possessing qualifications entitling them to be placed on the Medical Register of the United Kingdom. The salary attached to these posts will be at the rate of from £500 to £700 a year. An allowance, in lieu of quarters, at the rate in force for European officials will be granted, with the option of free Government quarters when such quarters are available. Pensions will be the same as those enjoyed by other African members of the Government service under the Pensions Ordinance. The duties of the African medical men, whom it is thus proposed to appoint to the Government service, will, unless an emergency should arise which rendered it necessary to employ them for other purposes, be entirely concerned with the indigenous population, and more especially with the poorer classes, and they will usually be stationed away from large towns. They will, as a general rule, be allowed private practice.

purified substance possesses the solubility characteristics of the globulin class of proteins, and consists of about 41·6 per cent. phospholipin and 58·4 per cent. of protein, the latter contains about 1·06 per cent. of phosphorus in firm combination. Addition of further amounts of phospholipin to the active material increases its activity. The presence in the tissues of an actual union between the protein and phospholipin elements is shown, and also that any alteration in this relation causes changes in the specific activity of the compound.

The Action of Tissue Extracts in the Coagulation of Blood, by C. A. Mills.—Tissue extracts accelerate the clotting of blood in a very definite manner. The active tissue substance will not react with the blood fibrinogen to form fibrin, either in vitro or in vivo, except in the presence of soluble calcium salts. Injected intravenously, rapidly, and in sufficient amounts, tissue extracts, or the purified active substance, cause intravascular clotting and death in a very definite manner. Injected slowly and in smaller amounts the blood is rendered non-coagulable, partially or completely, the non-coagulability apparently depending on a gradual removal of the greater part of the fibrinogen from the blood stream. A marked decrease in the alkali reserve of the plasma develops along with the development of the negative phase of coagulation, but is apparently not the cause of it. The injection of active tissue extracts into the blood stream so as to produce non-coagulability without clot formation is followed by an excretion of the active tissue substance apparently unchanged in the urine (dogs and rabbits). As observed by Loeb, there is present a class specificity in regard to the action of the tissue extracts on blood clotting. The specificity, however, is not absolute, since mammalian lung extract will accelerate the clotting of frog blood.

Certain Chemical Changes in the Blood after Pyloric Obstruction, by A. B. Hastings, C. D. Murray, and H. A. Murray.—The following changes in the blood were found to occur after closure of the pylorus in dogs—a marked increase in the CO_2 combining power of the blood and a striking fall in the concentration of Cl ions. These changes are confirmatory of the work of McCann and of McCullum. The authors further show a slight increase in the concentration of calcium in the serum, a marked increase in the sulphur and phosphorus concentration, and a variable diminution in the sodium concentration. The pH of the plasma, after operation, showed only an insignificant rise; at death it fell rapidly.

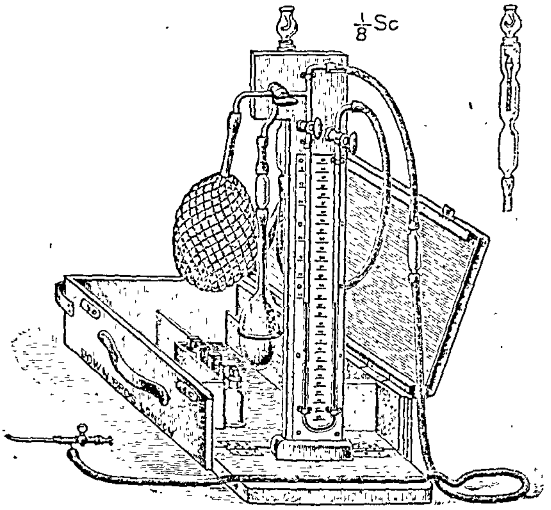
The Effect of Age on Pancreatic Enzymes, by F. Fenger and M. Hall.—Powdered pancreas preparations stored under ordinary conditions for one year show a material diminution in their diastatic and lipolytic activities, certain samples becoming almost inert. The proteolytic activity of the same samples, however, remains constant, indicating that trypsin is the most stable of the pancreatic enzymes.

The *Journal of the Royal Army Medical Corps* for September opens with a Preliminary Report on a Substitute for the Wassermann Reaction by Bt. Lieut.-Col. H. Marrian Perry and Major E. C. Lambkin. The "substitute" is the flocculation method of Dreyer and Ward,[1] or the Sigma test, which these officers tested against the Wassermann reaction in 220 cases, in which they found the Sigma test rather more delicate. They also compared the two tests in the examination of 22 cerebro-spinal fluids, where again this test proved the more delicate.—Dr. C. M. Wenyon, late Temp. Col., A.M.S., gives an account of malaria in Salonika and in the Farther East in 1919, in continuation of his preceding paper. Caucasia is a country highly malarious, as bad as Macedonia, but troops were not compelled to occupy so many of the worst positions, consequently fewer cases occurred; still, in one party of 305 men, 303 were attacked in about a month, they having no mosquito nets and no prophylactic quinine. In no case in Macedonia was there so high an incidence in so short a time, which is thought to show that prophylactic quinine does confer some benefit. Attempts were being made in the Caucasus before the war to deal with malaria, and some remarkable posters were exhibited at Tiflis. Mosquitoes survive the winter as larvæ in sheltered pools or more usually as mature females by hibernating—culex in caves, anopheles in huts or stables. The anopheles prefer stables which are warmer (buffaloes are "veritable stoves"); during the winter they occasionally wake up and make a meal of blood; on fine bright days they even come out in the sun and bite. The impregnated females in autumn become fat and as the weather cools collect in the barns; their ovaries develop slowly through the winter, and fully developed ovaries were found in March. Mosquito nets should be used from April to November inclusive. Malaria was more intense in the valleys because the anopheles in the valleys were chiefly the earlier breeding, and so earlier infected, *A. maculipennis* (May to November), but in the hills chiefly *A. superpictus* with a shorter season of infection (July to October). Of each variety about 6 per cent. were infected. It is possible that an infected female may carry malaria on through the winter, but generally it is the natives who are the carriers and who infect the early broods.

New Inventions.

ARTIFICIAL PNEUMOTHORAX APPARATUS.

THIS apparatus is a modification of that of Prof. Morelli, of Pavia, and its advantages are ease of manipulation and portability. The water-manometer is connected on the one hand with a collapsible india-rubber bag or reservoir of 400 c.cm. capacity and with a flexible tube leading to a hollow needle on the other hand. To the distal limb of the manometer is connected a safety-trap which prevents spilling of fluid. Air, nitrogen, or oxygen is run into the reservoir through the three-way tap on the left-hand side of the apparatus, the reservoir being almost filled but on no account distended. To this three-way tap is attached a glass bulb, containing sterilised cotton-wool, which acts as a filter for the gas, a similar filter being connected with the flexible tube leading to the needle. Gas having been run into the reservoir, the three-way tap is now turned so that all its openings are sealed, and the manometer taps are opened. After the usual aseptic precautions, the hollow needle is now thrust through the chest wall until the manometer reading indicates that the pleural cavity has been reached. The left-hand manometer tap is now closed and the three-way tap turned so that the coloured bead is uppermost. Gas will be drawn into the pleural cavity from the bag. From time to time the three-way tap is closed and the manometer tap opened in order to register the changes in intra-pleural pressure. As this pressure rises, gas will cease to flow into the chest, and the bag must be gently squeezed by the hand to continue the injection. When the reservoir is empty, the three-way tap is turned so that the coloured bead is to the left, and more gas is run in until the bag is just not distended as in the first instance. For primary inductions I use the Riviere cannula, but for refills a sharp-pointed Parry-Morgan needle is more convenient. The case contains four glass-stoppered bottles in safety clips. These may be filled with ether and tinct. iodi for sterilising the skin, novocaine solution for anæsthetising the tissues, and collodion for sealing the puncture wound. I have used this apparatus extensively during the past 12 months and have found it in every way satisfactory. It was made for me by Messrs. Down Bros.



GEOFFREY MARSHALL, O.B.E., M.D., M.R.C.P.,
Officer i/c Tuberculosis Department and Assistant Physician, Guy's Hospital.

---

[1] THE LANCET, 1921, i., 956.

owing to his recognition that it has a literature of its own. As befits a veteran in his subject, Dr. Lloyd Tuckey feels that much of what he used to preach has become of general acceptance and can be omitted; nevertheless, the reader will still derive benefit from a perusal of the history of the question and from the records of old experiments now rather relegated to the class of *vieux jeux*. On the whole, notwithstanding the excellence of the clinical record here reported in considerable detail, we are not able to dispel the feeling that the methods of actual hypnotism are of somewhat limited applicability, though for suitably selected cases recourse might be had more often to its therapeutic aid.

ADVANCED SUGGESTION (NEURO-INDUCTION).

Second edition. By HAYDN BROWN, L.R.C.P. Edin. London: Baillière, Tindall and Cox. 1921. Pp. 402. 10*s.* 6*d.*

SOME two years ago we reviewed the first edition of this book, in which the principles of psychotherapy by suggestion are elaborated along lines commending themselves to its author. The second edition contains three new chapters and is otherwise amplified and modified. In our view, Dr. Haydn Brown is on much surer ground when he expounds the practical value of his particular technique than when he endeavours to propound psychological "laws" to explain its action. Reduced to its lowest terms and stripped of the peculiar terminology which is employed ("synapsis is the process of convection from neurones to neurones, through synapses,") the method appears to consist in the attainment of "automatic relaxation, both of body and mind," whereupon "the sensible words you say to the patient will henceforth continue to claim his interest right through, provided they are of the slightest value to him." As far as we have noticed, however, notwithstanding a chapter on technique, the author nowhere appears to vouchsafe simple, definite information as to the production of this ideal state of automatic relaxation; in fact, he admits candidly that "I am no better able to tell a medical man what I do than a golfer can by mere words tell another how to play the game." In his hands, to judge by the records of this book (and who can tell what virtue there may not be in the handling of a treatment-hardened neuropath or psychopath by a "new" process, or at least by a process for which there is a new name?), the method of suggestion in psychotherapy has proved conspicuously successful. As in many other instances, we are convinced it is the man behind the method who, by his justifiable self-confidence and his practice of several golden rules (to our mind perhaps the most useful and practical paragraphs in the book), is able to impress his patient, to his lasting benefit.

EXAMINATION OF MENTAL CASES.

Examen des Aliénés. Nouvelles Méthodes Biologiques et Cliniques. By ANDRÉ BARBÉ, Médecin Aliéniste des Hôpitaux de Paris. With a Preface by Dr. SÉGLAS, Physician to the Salpêtrière. Paris: Masson et Cie. 1921. Pp. 178. Fr.8.

THIS little handbook is intended to assist the alienist in the objective examination of mental cases; it is a kind of vade mecum of such methods of clinical pathology as are likely to prove of service to the student of mental disease. Accordingly we find by far the larger portion of the book taken up with the cerebro-spinal fluid, the blood, the urine, the circulatory system, and the ductless glands; the space devoted to psychological investigation is trifling by comparison, psycho-analysis being dismissed in a page and a half. In fact, the book rather belies its title, though the aspect of the subject that it deals with is of equal importance with the psychological. The author is seemingly far from being convinced that all mental disease is psychogenic, and his handbook of clinical laboratory methods is likely to prove very useful to the student entering on an asylum course, for no preconceptions as to the psychogenesis of mental disorder can render nugatory the importance of painstaking examination of the physical side of the diseased organism. The latter, indeed, is in many cases calculated to throw light on the origin and type of the mental symptoms. Dr. Barbé's little compendium deserves a cordial welcome among asylum men.

TEXT-BOOK OF NEUROLOGY.

Lehrbuch der Nervenkrankheiten für Studierende und Praktische Ärzte. In 30 Vorlesungen. Second enlarged and completely revised edition. By ROBERT BING, Professor in the University of Basle. Berlin and Vienna: Urban and Schwarzenberg. With 162 illustrations, some in colours. 1921. Pp. 672.

THE first edition of Prof. Robert Bing's text-book of neurology was reviewed in these columns in March, 1914, and there is little wonder that, with the great increase in the study of the nervous system which the intervening years have seen, the chapters on the peripheral nerves, neurosyphilis, acute infective diseases of the nervous system, cerebral and cerebellar disease, dysglandular syndromes, and the psychoneuroses, have been almost entirely re-written. The book presents itself for consideration as an up-to-date product of the active and progressive school of neurology in Switzerland and deserves all the favourable commendation we can give it, nor does it need its author's apology for his inability during the years of the war to keep himself abreast of the neurological literature of foreign countries; after all, originality derived from the utilisation of personal material is as valuable as, or more than, a mere compendium of the ideas of other workers. Notwithstanding the disadvantage we felt, and feel, the author labours under in adopting the "lecture" form of presentation of his subject, we acknowledge the successful way in which he manages to cover the field, no small one at that, of modern neurology, though omissions of one sort or another will strike the reader. In the chapter on the dyskinesias, included in which is paralysis agitans, the pathological information supplied is very meagre; and in a volume of this size the few lines given to myotonia atrophica seem unsatisfying when pages are devoted to sclerodermia. Under tumours of the temporal lobe, reference is made in one line to the occurrence of hallucinations of taste and smell, but the significant addition of a peculiar "dreamy state" in many of these cases is not mentioned. It is easy, of course, to criticise sins of omission; the book is intended rather for practitioners than for neurologists by profession, and we can congratulate Prof. Bing on having worthily attained his aim.

THE SYMPATHETIC AND ASSOCIATED SYSTEM.

Le Sympathique et les Systèmes Associés. Second edition, revised and enlarged. By A. C. GUILLAUME. With Preface by Prof. PIERRE MARIE. Paris: Masson et Cie. 1921. Pp. 398. Fr.18.

ON its first appearance we gave this monograph a favourable review, commending it for its clarity and comprehensiveness and for its useful diagrams. The first edition was a slender brochure of some 160 pages; the second runs to nearly 400, and therefore contains a vast amount of new material, revolving mainly round the question of the clinical physiopathology of the sympathetic system. In its present form it will be found particularly useful to the clinician, to whose attention we again heartily recommend it. The new diagrams are conspicuously serviceable, though the errors we noted in Figs. 5 and 11 have not been corrected. The book is sorely in need of an index.

Surgery and Pathology, Dental Materia Medica, Dental Mechanics and Dental Metallurgy, with a practical as well as the written and oral examinations in the subjects of Dental and Oral Surgery, Pathology, and Mechanics. The candidate will be tested in the Treatment of Dental Diseases, in Operative Dentistry, the Administration of Anæsthetics, Orthodontics, and in Prosthetic and Mechanical Dentistry. Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations or other recognised examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £15 15*s.* payable for the dental diploma. Fees and schedules must be lodged with the Clerk not later than one week before the examination.

Higher Dental Diploma.—The College grants a Higher Dental Diploma which is registrable in the Dentists Register as an additional qualification. Every candidate for the Higher Dental Diploma shall produce evidence that he has been engaged in the study or practice of his profession as a Registered Dentist for at least one year subsequent to his having obtained the Licence in Dental Surgery of the College, or a Licence or Qualification in Dental Surgery specially recognised by the College. Particulars as to the examinations can be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, 49, Lauriston-place, Edinburgh. The fee payable by Licentiates of the College is £15 15*s.* For all other candidates £21. A fee of £10 10*s.* is retained for examination expenses in the case of referred candidates.

The examination embraces the following branches of Dental Science and practice: Dental Surgery, Anatomy, Pathology and Bacteriology, Prosthesis, Anæsthesia, and Dental Radiology. The examination will be clinical and practical as well as written and oral. Candidates will be expected to show a high degree of knowledge and skill.

Royal Faculty of Physicians and Surgeons of Glasgow.—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c., are in effect similar to those of the Royal College of Surgeons of Edinburgh, but embrace Dental Bacteriology. Candidates can enter for the First Examination in three divisions, the first embracing Physics and Chemistry, the second Dental Metallurgy and Dental Mechanics, and the third Anatomy and Physiology. The examination in Dental Mechanics is practical; and there is at the Final Examination an examination in Practical Dentistry conducted in a dental hospital. Copies of regulations, &c., to be obtained from Mr. Walter Hurst, Registrar, Faculty Hall, 242, St. Vincent-street, Glasgow.

Royal College of Surgeons in Ireland.—Candidates for the Licence in Dental Surgery are required to pass two professional examinations. Before the First Examination the candidate must produce evidence of having attended courses in Theoretical and Practical Chemistry, including Metallurgy and Physics, at a recognised institution; of having been registered as a medical or dental student by the General Medical Council; and of having attended courses of instruction in the following subjects at a recognised school of medicine: (*a*) Anatomy Lectures; (*b*) Dissections with Demonstrations; (*c*) Physiology, including Dental Physiology; (*d*) Practical Physiology and Histology, including Dental Physiology and Histology, Human and Comparative. Before the Final Dental Examination the candidate must have been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist, or under the direction of the superintendent of the Mechanical Department of a recognised Dental Hospital, and have attended, at institutions recognised by the College for the purpose, the following courses of instruction: (*a*) Dental Surgery and Pathology, Orthodontia, and the Materia Medica and Therapeutics applicable to Dental Surgery. Lectures. Two courses. (*b*) Dental Mechanics. Lectures. Two courses. (*c*) Dental Anatomy. Lectures. One course. (*d*) The practice of a Dental Hospital, or of the Dental Department of a General Hospital. Two years. He must also have attended Clinical instructions at a recognised General Hospital during the ordinary teaching sessions (nine months), and have been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a medical or dental student. One year's bona-fide apprenticeship with a registered dental practitioner, after being registered as a medical or dental student, may be counted as one of the four years of professional study. He must be 21 years of age.

In the First Dental Examination candidates will be examined in (A) Physics and Chemistry, including Practical Chemistry and Metallurgy. (B) Anatomy, Physiology, and Histology—General and Dental. All the subjects may be passed at the same time, or they may be passed in two groups, (A and B). The examination is partly written, partly vivâ voce, and partly practical.

In the Final Dental Examination candidates will be examined in General Pathology, Medicine, and Surgery; Dental Surgery, and Dental Pathology, with the Materia Medica and Therapeutics applicable to Dental Surgery; Dental Mechanics and Metallurgy; Orthodontia. Candidates must pass in all the subjects at one examination. The examination is partly written, partly vivâ voce, and partly practical, and includes the examination of patients and the performance of dental operations. Candidates are required to provide their own instruments and gold for filling. The First Dental Examination will commence on the first Mondays in the months of February, May, and November. The Final Dental Examination will commence on the second Mondays in the months of February, May, and November. The total fee for the Diploma in Dental Surgery is 20 guineas. Candidates must pay the fees for examinations from which they are exempted, unless when such exemptions have been granted in virtue of examinations passed before the Conjoint Board in Ireland.

University of Birmingham.—The teaching of Dentistry is undertaken by the University acting in association with the Birmingham Dental Hospital and the Birmingham Clinical Board. The instruction at the Dental Hospital is carried out under the direction of the University Dental Clinical Board, so that students may fully qualify themselves for the Dental Diploma (L.D.S.) of this and other universities and licensing bodies. There is a special and well-equipped Dental Museum and Laboratory. An Entrance Exhibition, value £37 10*s.*, is awarded annually at the commencement of the winter session. The following are the regulations for Degrees in Dentistry:—1. The degrees conferred by the University are those of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.). 2. All candidates for these degrees must pass the same Matriculation Examination as that required from candidates for Medical Degrees. 3. The degree of Bachelor of Dental Surgery is not conferred upon any candidate who has not obtained a Licence in Dental Surgery. The candidate is not eligible for the degree until a period of 12 months has elapsed from the passing of his examination for the Licence in Dental Surgery. Of this period at least six months must be spent in the dental department of a general hospital approved by the University. 4. *A.* In addition to the Licence in Dental Surgery the candidate must produce evidence that he has attended the courses required by medical students of the University in the following subjects and passed the Examinations held in the same for Medical and Surgical Degrees: (*a*) Chemistry and Practical Chemistry (*b*) Physics and Practical Physics, (*c*) Elementary Biology, (*d*) Anatomy and Practical Anatomy, and (*e*) Physiology and Practical Physiology. *B.* That he has passed the class examinations in: (*f*) One Special Course of Lectures on Medicine, (*g*) One Special Course of Lectures on Surgery, and (*h*) Pathology and Bacteriology. *C.* That he has attended courses and that the individual has acquired, if such as to interfere with his inherited characters, is bound to react detrimentally upon his health or powers of resistance to disease. This seems to be pushing the matter too far, for some inherited characters would bear modification. The book goes on to discuss certain of Nature's prophylactics against disease, which maintain good health and so favour in the struggle for existence the individual who adopts them. Such are exercise, proper food, fresh air and sunshine, adequate sleep, and the use of water. None of this is new, but though preached for ages only the lucky few are able to make full use of the preventive and remedial measures which Nature provides. For centuries man has at certain times cast aside the bonds of civilisation, and has gone away to enjoy the holiday that brings him in closer touch with Nature, knowing instinctively that is the sort of holiday most likely to bring him back to normal health.

The moral of the book is that the means employed by Nature to produce a healthy race should also be those resorted to by the individual to remain healthy, or to recover health when it is temporarily lost.

JOURNALS.

British Journal of Children's Diseases. Vol. XVIII. July–September. Edited by J. D. ROLLESTON, M.D.—Dr. Bernard Myers contributes a paper on a Case of Oxycephaly in a girl aged 12 with tracings of the skull and skiagrams. The patient belonged to the group of oxycephaly cases described by H. Morley Fletcher in which changes occur in the first few months of life in the shape of the head, prominence of the eyes being observed at the same time. In such cases the condition becomes more evident during the first two years and is accompanied by increasing impairment of vision. The paper contains an account of the ophthalmoscopic examination of the case made by Dr. Bickerton and of the X ray findings by Dr. Martin Berry.—In a paper on Rickets, with Special Reference to its Ætiology, Early Manifestations, and Treatment, Dr. James Burnet, of Edinburgh, emphasises the fact that "rickets is essentially, in the first instance at all events, a disease of alimentation," and protests against its being regarded as a disease of bones. He is firmly convinced that rickets could be practically stamped out if the sale of "infant foods," dried milk, and condensed milk were strictly regulated, and medical men were warned against these articles as a routine method of infant feeding. Other causes of rickets, such as bad hygiene, he regards as insignificant compared with improper feeding. The early manifestations of rickets are divided by Dr. Burnet into catarrhal phenomena, nervous phenomena, and vaso-motor phenomena. Catarrhal phenomena, which are probably the earliest manifestations of all, consist in gastro-intestinal symptoms, such as vomiting and diarrhœa and a marked tendency to nasal, aural, and bronchial catarrh. The nervous phenomena include restlessness and irritability, attacks of crying, disturbed sleep, and convulsions. The principal vaso-motor phenomena are profuse sweating and the appearance of a red line when the finger-nail is lightly drawn across the skin. In the treatment of the disease Dr. Burnet attaches special importance to prophylaxis. If breast milk is not available he considers that scalded cows' milk, pure or diluted with water, or citrated, is the only proper substitute. As an adjunct, cod-liver oil may be ordered either pure or in the form of a good emulsion. Fresh air and sunlight and massage with olive oil are useful additional measures.—Dr. W. McKim Marriott, of St. Louis, writes on Abnormal Metabolism in Infancy and its Relationship to Symptomatology.—Mr. W. M. Mollison reports two cases of Paralysis of Eye Muscles Occurring in Connexion with Mastoiditis: Recovery. In the first case the paralysis came on after operation for acute symptoms arising in the course of chronic suppuration, and in the second in the course of simple acute mastoiditis. In neither case was any extension of disease found towards the tip of the petrous bone. Both cases had certain features in common—namely, pain about the affected eye, nausea and vomiting, slow pulse combined with paralysis of the levator palpebræ superioris, but in the first case paralysis of the third cranial nerve and in the second of the sixth cranial nerve was present. Some form of meningitis was probably responsible for involvement of individual cranial nerves, though the evidence was very poor in the second case.—The Society Intelligence contains résumés of cases of pædiatric interest shown at various sections of the Royal Society of Medicine and an account of recent meetings of the Philadelphia Pediatric Society and Société de Pédiatrie of Paris.—The abstracts from current literature are devoted to tuberculosis and dermatology.

The Journal of Biological Chemistry (Vol. XLVI., 1921) contains the following papers of interest on various problems of nutrition:—

Studies in the Digestibility of Proteins in Vitro. (I) The Effect of Cooking on the Digestibility of Phaseolin, by H. C. Waterman and C. O. Johns.—Preliminary work on a method for the comparison of protein digestibilities is described, and the possibility of developing an approximately quantitative method is discussed. The experiments indicate that phaseolin (navy bean) is rendered more readily digestible by boiling with distilled water. Cooking for five minutes gave a detectable increase in digestibility, while cooking for three-quarters of an hour apparently produces the maximum effect.

The Available Carbohydrate in Thrice-boiled Vegetables, by L. O'Reilly and E. H. McCabe.—With the introduction of thrice-boiled vegetables into the dietary of diabetics it becomes of importance to know the carbohydrate content available to the organism. From their investigations the authors conclude that only in the case of a few thrice-boiled vegetables is it possible to free them completely from carbohydrate as determined by taka-diastase. The use of 20 parts of water as compared with 10 for each boiling makes the extraction more complete, and by this method vegetable marrow, lettuce, and celery can be completely freed from available carbohydrate, and canned spinach, canned asparagus, turnips, beets and onions rendered approximately carbohydrate free. Canned string beans, cauliflowers, pumpkins, cabbage and carrots still retain about 0·5 per cent. available carbohydrate. The addition of sodium bicarbonate 0·05 to 0·1 per cent. assists complete extraction.

Antiscorbutic Potency of Milk Powders, by E. B. Hart, H. Steenbock, and N. R. Ellis.—Milk powders vary in their antiscorbutic properties. Apart from the factor of the initial vitamin content of the milk as influenced by feed, the powders vary in their potency with the process used in their manufacture, the spray process being more destructive of antiscorbutic vitamin than the Just process. These results should in no way condemn the milk powders made by the spray process; they only point out their limitations when used as the sole source of nutrients in infant feeding.

Some Observations on the Stability of the Antiscorbutic Vitamin and its Behaviour to Various Treatments, by N. R. Ellis, H. Steenbock, and E. B. Hart.—Desiccation of cabbage in an atmosphere of carbon dioxide for 35 hours at 65°C. did not prevent the destruction of the antiscorbutic vitamin. Fermentation processes involved in the making of sauerkraut from cabbage and silage from corn result in the destruction of the antiscorbutic factor. This vitamin was not removed from the orange-juice by ether or by aeration, but whereas oxidising agents caused its destruction, mild reducing action was without effect. Blood charcoal and the Chamberland filter removed a measurable amount of this vitamin from orange-juice.

A Study of the Chlorine Content of Milk and Blood after the Ingestion of Sodium Chloride, by W. Denis and W. R. Sisson.—By the administration to lactating goats of a sufficiently large amount of sodium chloride to produce an 18 per cent. increase in the blood plasma content, the chlorine content of the milk is also raised. Coincident with this increase, there is a great diminution in the volume of milk.

The Determination of Carbohydrates in Vegetable Food, by V. C. Myers and H. M. Croll.—A relatively simple colorimetric method is described for the determination of the amount and form of the available carbohydrate in vegetable foods.

Other articles dealing with more general bio-chemical subjects may be briefly summarised thus:—

Contributions to the Biochemistry of Iodine. IV. The Effect of Thyroxin on Growth in White Rats and in Rabbits, by A. T. Cameron and J. Carmichael.—Using decrease of growth rate in growing rats, hypertrophy of heart, liver, kidneys, and adrenals, and decrease of growth rate of thyroid, as tests, thyroxin, when administered by mouth, produces the same qualitative effects as does desiccated thyroid. Quantitatively, when compared on a basis of iodine content, the effects of thyroxin are distinctly less. This is probably due to bacterial decomposition; thyroid acts as a shield. The hypertrophy of heart and lymphatic tissue resembles that observed in cases of hyperthyroidism.

The Chemical Nature of Tissue Coagulins, by C. A. Mills.—The active agent of tissue extracts is a protein-phospholipin compound, and the phospholipin alone, although possessing a slight effect on blood coagulation, accounts only for a small fraction of the total activity of the extract. Splitting of the compound destroys its activity, but reunion restores its action. The isoelectric point of the compound lies between $N \times 10^{-5}$ and $N \times 10^{-6}$ acidity. At this point the material precipitates from its solutions without loss of its activity on coagulation. The school in the kingdom, and the fullest opportunities for study are offered to students preparing for any of the professional examinations. Instruction adapted to the requirements of students preparing for the B.D.S. Degree and the Dental Diplomas of the University, the Royal College of Surgeons of England, and of other licensing bodies is given throughout the session both at the University and at the Dental Hospital of Manchester adjoining the University. The required general hospital practice is taken at the Manchester Royal Infirmary. Women students are admitted to the classes in the Dental Department, and for them common rooms are provided. The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 93 guineas, payable in three equal yearly instalments. The composition fee for candidates for the University Diploma in *Dentistry is 83 guineas, payable in three equal yearly* instalments. The composition fee for candidates for the L.D.S. of England is 93 guineas, payable in three equal yearly instalments. Students who have already served their apprenticeship with a private practitioner, and who propose to complete the final portion of their attendance at the University and at an approved dental hospital, will be required to pay the composition fee in two equal instalments at the commencement of the first and second years of studentship. The composition fee does not include the hospital fees, the examination fees, nor the fee for the conferment of the degree or the diploma.

National University of Ireland.—This University grants the degrees of Bachelor of Dental Surgery and a degree of Master of Dental Surgery. A student may not be admitted to the Degree of Bachelor of Dental Surgery unless a period of not less than four years shall have elapsed from the date of his matriculation, during which period he must have pursued an approved course of study of not less than nine terms. For the degree of Bachelor of Dental Surgery candidates must pass four examinations, the first two being the same as those for the first and second examination in Medicine. The subjects of the third examination are Dental and Practical Pathology, Dental Surgery and Dental Medicine, the subjects of the fourth being Dental Surgery and Pathology, Dental Mechanics, Operative Dentistry, Orthodontia, and Dental Materia Medica. A candidate for the degree of B.D.S. must produce evidence of having been engaged during a period of two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist, or under professional direction in the mechanical department of a dental hospital approved by the University. A portion of or the entire period may be served before commencing study for the degree of B.D.S., but no portion so taken prior to commencement of study shall count as part of the four years of Dental Study. The degree of Master of Dental Surgery will not be granted until three years after the B.D.S. has been obtained.

Queen's University of Belfast.—At the beginning of session 1920–21 a Department of Dentistry was opened, and in due course the University expects to confer a Licentiate in Dental Surgery, a Bachelor of Dental Surgery, and a Master of Dental Surgery. Lecturers have been appointed in Dental Surgery, Dental Mechanics, Dental Metallurgy and Materia Medica, and Orthodontia.

TEACHING INSTITUTIONS IN DENTISTRY.

See also under Universities of Birmingham, Leeds, Liverpool, and Manchester above.

London.

Royal Dental Hospital of London, School of Dental Surgery, Leicester-square.—A school of the University of London, and women are now admitted as students and are eligible for all hospital appointments and school prizes. The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery. The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 5 P.M., there being one staff for the morning and another for the afternoon of each day. Pupils are received for the training in dental mechanics recognised by the curriculum. The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery. The five house surgeoncies are held for six months each and are open to all qualified students. The lecturers, in addition to their lectures, give special demonstrations on the Microscopy of Dental Anatomy and Dental Surgery. The lecturer on Dental Mechanics also gives practical demonstrations in the laboratory. There is an Entrance Scholarship in Chemistry and Physics of the value of £50. One Entrance Scholarship in Dental Mechanics and Metallurgy, value £25, open to pupils of the Hospital only. One Entrance Scholar*ship of £25 in Dental Mechanics, open to pupils of* private practitioners. The Saunders Scholarship of £20 and Saunders Prize of £5 awarded to second year students. The Storer Bennett Research Scholarship for Scientific Research in any branch of Dental Surgery, value £50, is awarded triennially. The Alfred Woodhouse Scholarship of £35 and the Robert Woodhouse Prize of £10 for Practical Dental Surgery. Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses at the end of the summer and winter sessions. Fee for two years' hospital practice required by the curriculum, including lectures, £70 in one payment, or £73 10*s.* in two yearly instalments. The curriculum requires two years to be passed at a General Hospital; the fee for this is about £63. Both hospitals can be attended simultaneously. For the lectures in Chemistry and Physics for the Preliminary Science Examination £13 13*s.* The fee for the instruction in Dental Mechanics and the two years' hospital practice required by the curriculum is £200 if paid in one instalment, or 200 guineas if paid in three equal instalments. The fee for tuition in Dental Mechanics is £70 per annum; for one year's hospital practice £28. The Winter Session opens on Oct. 3rd.

University College Hospital Dental School, corner of Great Portland and Devonshire-streets, W.—This Hospital and School has recently been thoroughly reorganised, and is now fully equipped with all the most modern appliances. Students are entered as students of University College Hospital, and, as such, attend the classes of Chemistry, Physics, Anatomy, and Physiology in University College, which is a few minutes' walk from the Dental Department in Great Portland-street, hitherto known as the National Dental Hospital, the first Dental School to admit Women Students. Practical courses to comply with the R.C.S. curriculum are held. Clinical Lectures and Demonstrations are given, and each student on entering passes through a preliminary course under a demonstrator. Two Entrance Exhibitions, of the value of £40 and £20, are open for competition. Prizes are open for competition at the end of each course of lectures. Composition Fees: Comprising two years' Dental Mechanics, Chemistry, Physics, Anatomy, Physiology; two years' Hospital Practice, Medicine, Surgery, and Dental Lectures (four years): 1st year, £77; 2nd year, £56; 3rd year, £92; 4th year, £32. Total, £257. Medical Men: Two years' Mechanics, and Dental Practice and Lectures: 1st year, £102 6*s.*; 2nd year, £70. Total, £172 6*s.* For a six years' course of medical and dental education comprising the whole of the dental curriculum and the curriculum for the M.R.C.S., L.R.C.P. diplomas: 1st year, £113; 2nd year, £70; 3rd year, £73; 4th year, £60; 5th year, £73; 6th year, £49; total, £438, in six instalments payable in advance.

Guy's Hospital.—The work of the Dental Department begins daily at 9 A.M. both in the extraction rooms and in the conservation room. The Extraction Rooms: A new Dental Out-patient Department has been provided. There is ample accommodation for ordinary extractions and anæsthetic extractions, together with waiting- and retiring-rooms. Patients

Supplement to the Students' Guide.

DENTAL SURGERY.

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without a licence in dentistry; but it is of eminent advantage to take the L.D.S., otherwise few dental appointments at general or special hospitals or dispensaries are available.

THE DENTISTS' REGISTER.

The Registration of Dental Students is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies, including two years' instruction in mechanical dentistry. The two years of instruction in mechanical dentistry, or any part of them, may be taken by the dental student either before or after his registration as a student. When a student can show evidence of regular pupilage in mechanical dentistry to a registered practitioner prior to the passing of a preliminary examination he may be allowed to antedate for a period not exceeding one year prior to the passing of a preliminary examination.

It is necessary for anyone practising Dental Surgery in this country to be on the Register, and no foreign qualifications are recognised, except the Dental Diploma granted in Belgium after examination by the Provincial Medical Commission, provided the holder has obtained the grade of "Candidate in Medicine" at one of the four Belgian Universities. Persons with Colonial and Foreign qualifications which have been obtained after a four years' curriculum can apply for special registration. Certain dental qualifications granted in Australia and New Zealand are also registrable. The Royal Colleges of the United Kingdom and ten of the Universities grant degrees or licences in Dental Surgery.

THE DIPLOMA-GRANTING BODIES IN DENTISTRY.

The Royal College of Surgeons of England grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have registered as dental students after Jan. 1st, 1897. Candidates are required to pass three examinations: the Preliminary Science Examination, the First Professional Examination, and the Second Professional Examination. 1. Preliminary Science Examination.—This is identical with Part I. of the First Examination of the Examining Board in England. Candidates who commenced professional study on or after Oct. 1st, 1913, must pass the Preliminary Science Examination before commencing the courses required for the Second Professional Examination. 2. The First Professional Examination.—The candidate must produce evidence of instruction in Dental Metallurgy and Practical Dental Mechanics. The Examination consists of Part I. (Mechanical Dentistry), Part II. (Dental Metallurgy), the examination in Dental Metallurgy being by written paper, and Part III. (*a*) General Anatomy and Physiology, (*b*) Dental Anatomy and Physiology conducted by papers and vivâ voce examination. The parts may be taken together or separately. III. The Second Professional Examination.—This is divided into two parts: (*a*) the General, (*b*) the Dental. The General part must be passed before the Dental portion. The instruction is obtained partly at a General Hospital and partly at a Dental Hospital.—The Second Professional Examination consists of: Part I., General Surgery and Pathology; Part II., Dental Surgery and Pathology, and Practical Dental Surgery. There is a written and vivâ voce examination in each part and a practical examination as well in Part II. Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony. Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination for any degree or qualification in Medicine or Surgery registrable under the Medical Act of 1886. Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and University above mentioned. The fee for the diploma is 20 guineas, and is payable as follows: Preliminary Science Examination, for each admission to Part I., £3 3s.; Part II., £2 2s. First Professional Examination, for each admission to Part I., £4 4s.; Part II., £1 1s.; Part III. (*a*) £2 2s.; (*b*) £2 2s.; Second Professional Examination, for each admission to Part I., £2 2s.; Part II., £4 4s. Synopses of examinations and all further information can be obtained from the Secretary, Examination Hall, Queen-square, London, W.C. 1.

Royal College of Surgeons, Edinburgh.—Regulations giving a list of Preliminary Examinations recognised for obtaining the Licence in Dental Surgery, as well as of the subjects of the Professional Examinations, may be obtained from Mr. D. L. Eadie, Clerk to the Royal College of Surgeons, at 49, Lauriston-place, Edinburgh. Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient. Candidates must also have attended a course of instruction at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the Diploma in Surgery. In addition they will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, special courses of lectures and instruction in Anatomy and Physiology (Human and Comparative), Surgery, Pathology, Materia Medica, Dental Histology, and Practical Dental Mechanics and Metallurgy; two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College. Practical instruction in Mechanical Dentistry from a registered Dentist, or in the Mechanical Department of a recognised Dental Hospital and School, for three years. Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination, and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both. But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations, and will admit to the Final Dental Examination only. Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma. First Professional Examination: The candidate must have attended the required courses. The examination embraces (1) Chemistry and Physics; and (2) Anatomy and Physiology. The fee is £5 5s. for the complete examination, and £3 3s. is payable for each division. In all cases of rejected candidates the fee for re-entry is £3 3s. Second Examination: The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is 21 years of age, and must pay a fee of £10 10s., for re-entry £5 5s. The examination embraces (1) Surgery and Medicine; and (2) the special subjects of Dental Anatomy and Physiology, Dental

5 guineas, open for competition to all Students. Extraction prize, value 2 guineas, open for competition to all Students. A prize in Orthodontics, value 5 guineas, open to all Students. All communications should be addressed to the Warden, School of Dentistry, the University, Leeds.

Dental Hospital of Manchester.—This hospital is in association for teaching purposes with the University of Manchester and the Royal Infirmary, and is in the centre of a very large population. Courses of study are provided to meet the requirements of the various examining bodies, including those of the University of Manchester for the qualifications L.D.S. and B.D.S., and the L.D.S. of the Royal College of Surgeons of England. Clinical instruction is given by the members of the staff and by the house surgeons and demonstrators, and also by the honorary anæsthetists in the administration of nitrous oxide gas; a special class in anæsthetics is conducted by the clinical tutor in that subject, and a class for instruction in porcelain and gold inlay work by the demonstrator specially appointed for that work.

Ten prizes, varying in value from £2 to £12 12*s.*, are awarded annually.

For the whole course of hospital instruction for the L.D.S. (including two years' mechanical training) the fee is £131 5*s.*, paid in instalments. For the two years' Operative Course only, £26 5*s.*, paid in two instalments. For the whole course of hospital instruction for the B.D.S. degree (including mechanical training), £168, paid in instalments. Additional practice in Dental Mechanics may be taken by pupils who have already received their mechanical training elsewhere, at a fee of £36 15*s.* for six months.

All the courses of instruction are open to women students.

Copies of the Prospectus will be forwarded on application to Mr. J. Hilditch Mathews, Dean.

Newcastle-upon-Tyne Dental Hospital and School.—This hospital is centrally situated (within five minutes of the various colleges, infirmary, and railway station); the rooms are well lighted and thoroughly equipped for carrying on the work. Dental surgeons and an anæsthetist attend each morning. A tutorial dental surgeon and a prosthetic tutor is also in attendance. The Composition Fee for the special Dental Lectures and Dental Hospital Practice is £60 4*s.* if paid in one sum, or £62 6*s.* if paid in two instalments of £31 3*s.* The Composition Fee for the Lectures at the Colleges of Medicine and Science is £57 10*s.*; in addition to this there is a library and an athletic fee. Particulars of the fee for General Hospital Practice may be obtained from the Senior House Physician, Royal Victoria Infirmary, Newcastle-upon-Tyne. Medals and Certificates of Merit are granted to students showing certain standards of proficiency in the various classes at the Dental School. The prospectus of the Dental Hospital and School, containing full information, may be obtained from either Mr. J. T. Jameson, 12, Windsor-crescent, Newcastle-upon-Tyne, Dean, or Mr. James Coltman, 13, Ellison-place, Newcastle-upon-Tyne, Vice-Dean.

Devon and Exeter Dental Hospital, 24, Southernhay West, Exeter.—Established 1880.—The hospital is open on Mondays, Tuesdays, Wednesdays, Thursdays, and Fridays, and patients are admitted between the hours of 9 and 11 A.M. Students attend the practice of the hospital under the control of the medical officers. Honorary treasurer, Mr. J. M. Ackland; secretary, Mr. Albert G. Littlejohn.

SCOTLAND.

The Incorporated Edinburgh Dental Hospital and School.—The Edinburgh Dental Hospital and School is located in spacious and well-equipped buildings at 30, 31, and 32, Chambers-street and offers special advantages to dental students. The General Courses required for the Dental Diploma may be taken in the Medical School of the Royal Colleges of Physicians and Surgeons or in the University schools. The general hospital attendance and clinical instruction are taken at the Royal Infirmary. The University, Medical Schools, and Royal Infirmary are within three minutes' walk of the Dental Hospital. The special courses are taken in the hospital. The Dental Hospital practice, extending over two years, affords a student ample opportunity for a full acquaintance with every branch of dentistry. The hospital admits a limited number of indentured pupils. They receive their instruction in Mechanical Dentistry concurrently with the general and special courses. A premium of 60 guineas is payable with each such pupil. The practice and lectures of the hospital are recognised by, and qualify for, all the Licensing Boards. The cost of the hospital outfit of instruments is included in the Dental Hospital fee of £42. The minimum cost of classes and Diploma for the whole course of dental instruction amounts to £98 17*s.* Those students who desire to take a Medical and Surgical Diploma in addition to the L.D.S. have in this school admirable facilities for so doing. The triple qualification of the Royal College of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow is recommended. The minimum cost of Professional Education, the Triple Qualification, and the Licence in Dental Surgery amounts to £172 19*s.* The Higher Dental Diploma (H.D.D.) of the Royal College of Surgeons affords an opportunity of obtaining a higher qualification subsequent to registration. The Prospectus, with full information, may be obtained by application to the Dean or the Assistant Secretary.

Incorporated Glasgow Dental Hospital, 15, Dalhousie-street, Glasgow.—The School is open to Men and Women Students, and Lectures are given on Dental Surgery, Operative Dental Surgery, Orthodontia, Dental Anatomy and Physiology, Pathology, Dental Histology, Dental Mechanics, Crown and Bridge work, Dental Metallurgy, Dental Bacteriology, and Anæsthetics. A new Radiography department has been added. Lectures on general subjects required for Dentistry may be taken at the University or at one of the extramural schools where special provision is made for Dental Students. Composition fee for two years' Hospital Practice and Lectures special to Dentistry, £50 on entry, or in two instalments of £31 10*s.* and £21. Full information may be had on application to the Dean.

Glasgow Royal Infirmary (Dental Department).—Mr. W. R. Taylor attends at the Royal Infirmary at 9 A.M. on Wednesdays and other days as arranged. The following course in the curriculum can be taken at St. Mungo's College: Anatomy, six months; Practical Anatomy, nine months; Physiology, six months; Chemistry, six months; Practical Chemistry with Metallurgy, three months; Surgery, six months; Medicine, six months; Materia Medica, three months; Clinical Surgery, six months; Dental Surgery, six months, and attendance for two years on the dental department of the hospital. The attendance on the Dental Clinic is free to students of the hospital.

IRELAND.

Incorporated Dental Hospital of Ireland, Lincoln-place, Dublin.—All Dental Students who have passed their First Dental Examination in the Royal College of Surgeons in Ireland (or an equivalent examination or examinations) are admissible to the Clinical Instruction of the Hospital. In addition to Clinical Instruction and Special Demonstrations, courses of lectures are given at the hospital on Dental Surgery and Pathology, Mechanical Dentistry, the Administration of Anæsthetics, Orthodontia, Dental Anatomy, and Dental Materia Medica. Practical instruction is also given in Anæsthetics.

Fees.—Dental Hospital Practice (each year), £18 18*s.*; Lectures, £5 5*s.* Registered dentists who are members of the British Dental Association will usually be permitted to take out a three months' course for a fee of 6 guineas. The course in practical Dental Mechanics can be taken in the Hospital Laboratory. Further particulars can be obtained from the Dean.

passed the class examinations in: (*k*) Dental Histology and Patho-Histology, (*l*) Comparative Dental Anatomy, and (*m*) Dental Surgery and Prosthetic Dentistry. *D.* That he has received instruction in the Clinical Examination of living cases at the dental department of a general hospital for a period of not less than six months. 5. The Final Examination will deal with the subjects in Classes *C* and *D*. 6. On the expiration of 12 months from the date of passing the Examination for the Degree of Bachelor of Dental Surgery, the candidate will be eligible for that of Master of Dental Surgery. 7. For this degree candidates will be required to submit a thesis containing original work and investigations in some subject connected with Dentistry, which theses shall be submitted to examiners to be nominated by the Dental Advisory Board.

University of Bristol.—Candidates for the degree of Bachelor of Dental Surgery must be not less than 21 years of age and shall have pursued the courses prescribed by University regulations during not less than five years, of which three shall have been passed in the University, and shall have been registered as dental students by the General Medical Council. All candidates for the degree of B.D.S. are required to satisfy the examiners in the several subjects of four examinations. The First Examination: The subjects are Chemistry, Physics, and Zoology, and the curriculum extends over one year.* The Third Examination: The subjects are Dental Mechanics, Dental Metallurgy, and Dental Materia Medica, and the candidate shall produce evidence of having served for three years an approved pupilage in Dental Mechanics. The Second Examination: The subjects are Anatomy, Physiology, and Histology, Dental Anatomy, and Dental Histology. The Final Examination: The subjects are Medicine and Surgery, Dental Surgery (including Prosthetics), Operative Dental Surgery, and Dental Bacteriology. Degree of Master of Dental Surgery: Candidates shall be Bachelors of the University, shall present a Dissertation on some subject of Dental Surgery to be approved by the Examiners, and pass an examination in Dental Surgery. Diploma in Dental Surgery: Candidates need not be undergraduates, but shall have passed an entrance examination satisfactory to the University before being admitted to any professional examination; the curriculum extends over four years. A three years' pupilage in Mechanical Dentistry is required and four examinations must be passed, the subjects of which differ only from those of the B.D.S. in that Zoology is not required for the First Examination, and Medicine is not required for the Final Examination. Candidates who are already registered medical practitioners shall be further exempted from study and examination in Physics and Chemistry, Anatomy, Physiology and Histology, Medicine, and General Surgery.

University of Durham.—Every candidate for the Licence in Dental Surgery must be registered as a dental student. There are four Examinations. The subjects are:—*First:* (*a*) Chemistry; and (*b*) Physics. *Second:* (*a*) Dental Mechanics, Theoretical and Practical; (*b*) Dental Metallurgy. *Third:* (*a*) Anatomy; (*b*) Physiology and Histology; (*c*) Dental Anatomy and Dental Histology; and (*d*) Dental Materia Medica. *Final:* (*a*) Surgery; (*b*) Dental Surgery, including Prosthetics and Orthodontia; (*c*) Operative Dental Surgery, Practical Examination; and (*d*) Dental Pathology and Bacteriology. A candidate before presenting himself for examination is required to furnish certificates of instruction in the following subjects, attended after registration as a dental student at recognised Colleges or Schools:—*First Examination:* Chemistry and Physics. *Second Examination:* Dental Mechanics and Dental Metallurgy. *Third Examination:* Anatomy, with Dissections; Physiology; Histology; Dental Anatomy and Physiology; Dental Histology; and Dental Materia Medica. *Final Examination:* Dental Hospital Practice (two years); General Hospital Practice (nine months); Medicine Lectures (two terms); Surgery Lectures (two terms); Dental Surgery and Pathology (a course of not less than 20 lectures); Dental Bacteriology (three terms); Operative Dental Surgery (not less than 12 lectures); and Anæsthetics (a course of not less than one month).

Before admission to the Final Examination each candidate must furnish evidence (1) of having attained the age of 21 years; (2) of having undergone a three years' pupilage in Mechanical Dentistry with a registered dentist; and (3) of having been engaged in professional study for at least four years subsequent to registration as a dental student. The examinations will be held concurrently with the medical examinations, and the fees payable by candidates are as follows: First Examination, £2 10*s.*; Second Examination, £2 10*s.*; Third Examination, £3 10*s.*; Final Examination, £3 10*s.*; fee for Licence, £3; total, £15. For re-examination: First Examination, £1 10*s.*; Second Examination, £2; Third Examination, £2 (in one part only, £1); Fourth Examination, £2. The practical examinations in dentistry will be conducted at the Newcastle Dental Hospital.

University of Leeds.—The degrees in Dental Surgery are Bachelor of Dental Surgery (B.Ch.D.) and Master of Dental Surgery (M.Ch.D.). All candidates for the degree of Bachelor of Dental Surgery shall be required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the First Examination, and to have completed such period of pupilage or hospital attendance, or both, as may be prescribed by the regulations of the University. No candidate will be admitted to the degree who has not attained the age of 21 years on the day of graduation. The classes in the Department of Dentistry begin on Oct. 3rd. The instruction in the Preliminary subjects of Chemistry, Physics, and Biology are given at the University in College-road. The classes in the other subjects and the systematic courses in Dental subjects are held in the School of Medicine of the University in Thoresby-place. The clinical instruction is given in the Dental Department at the Leeds General Infirmary. Applications for the prospectus should be made to the Dean of the Faculty of Medicine.

University of Liverpool (Liverpool Dental Hospital Clinical School and School of Dental Surgery).—The University grants a Licence in Dental Surgery (L.D.S.) and degrees in Dental Surgery (B.D.S. and M.D.S.). The courses of systematic instruction are given in the University buildings, five minutes' walk from the Dental Hospital. The two institutions are closely associated, and the management of the curriculum is in the hands of the Board of Dental Studies. The Dental Hospital, covering a site of 672 square yards, is equipped in each department with every modern accessory and receives constant additions. The laboratory is in charge of a skilled dental mechanic under the supervision of the Director of Dental Education and Dental Staff, and students are able to undertake at the hospital the whole of their training in Mechanical Dentistry. The times of the lectures at the University are arranged to meet the convenience of students, thus allowing the maximum time for attendance upon Dental Hospital practice. Fees: The fees for the complete courses, including Pupilage and Hospital Practice, are as follows: Degree of B.D.S., £237 10*s.*; M.D.S., £18 5*s.*; L.D.S. (Liverp.), £100; L.D.S. (other licensing bodies), £203. Further information may be had from the Director of Dental Education, Prof. W. H. Gilmour.

University of Manchester.—In the University of Manchester the Dental Department forms an integral part of the Faculty of Medicine. This contains a series of laboratories, lecture rooms, and museums which will bear comparison with those of any other maimed; the interested world is beyond the stage where verbal communication can possibly achieve the desirable end. But, on the whole, publication becomes less feasible as the work becomes more serious because the available public becomes progressively smaller, and it is difficult to see how many sober scientific journals are to be maintained. The great technical weeklies are subsidised by their advertisements, which incidentally are not the least useful or interesting part of their contents; in America a good many journals are helped out by endowments, a fact which explains their moderate price; journals with a big circulation, such as those of the chemical societies, have an available margin for economies. But most of our valuable periodicals have a very limited circulation, they rely on relatively small societies whose members are, for the most part, much poorer than they were and their very existence seems to be threatened.

---

* Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the first examination for either the B.D.S. or the L.D.S., and will be regarded as having completed one year of study.

Possible alleviations or solutions fall roughly under two heads. In the first place various plans have been suggested depending on alterations in the form of publication, and Mr. Brierley has a concrete proposal to put forward. Premising that the readers of scientific papers want to acquaint themselves with either a summary statement of the author's conclusions or the fullest details of the observations on which his conclusions rest, he points out that the present method of a curtailed publication in extenso satisfies nobody; it is too full for a summary, too meagre for critical examination. He suggests that the journals should contain very full summaries with the minimum of original data necessary for their comprehension; these would be read or looked through by those generally interested in the compartment of science dealt with by the journal. For the specialist the results of the inquiry would be written up in full detail with all the original data, and these memoirs, with any germane pictures or specimens, would be deposited in some central office where they would be available for consultation by the few people really interested and competent. It is a scheme to which everyone will have a spontaneous repugnance, but if, as Mr. Brierley bids us, we face reality, it may be the best way out of our troubles. It is at any rate something to be thankful for that scientific memoirs are susceptible to condensation; it is reported that the Russian novelists are reduced to reading their works aloud to those who want to listen or who cannot get away. The second line along which relief may be sought involves an alteration in the material rather than in its method of reproduction. As Mr. Brierley indicates, many of the papers published are merely records of time spent and have no permanent and little (if any) temporary value in the advancement of learning. The curious and rather secretive interest in things which used to lead to discovery has been the subject of what almost amounts to a stunt; research has become a business and has to justify itself and those who engage in it. But is this really progress? Is not the real solution of the cost of printing to be found, not by curbing the rapacity of compositors as Prof. Oman suggests, but by setting a different standard of merit for what ought to be put into type? If those contributions only were printed which really made a contribution to knowledge and, what is perhaps more important, indicated further lines of advance, much of the present trouble might disappear. The others could be printed in the briefest abstract. But the lot of editors might then be unhappier than it now is.

The cynic may remind us that some of Cavendish's papers have only this year been transferred from manuscript to print and that, after all, publication does not matter very much; the pessimist, that the dull formalism into which so much of scientific literature has fallen deserves no better fate than it has met. Re-thinking is doubtless needed in several directions; the importance of publication has perhaps been exaggerated, it would be as well for scientific writers to realise that it is possible to be serious without being solemn. But someone must find a plan for making publication possible for material which deserves it.

◆

Treatment of Stigma Diseases in General Hospitals.

It is curious how the attitude of man towards different diseases has changed from time to time, a disease like tuberculosis, for example, being regarded by our ancestors as a pathetically genteel state to which the victims of unrequited affections were peculiarly liable. Cancer, on the other hand, was discussed by our grandparents with vague horror, and when it occurred in the family it was referred to with tactful anonymity. At the present time the subject of cancer is ventilated with call-a-spade-a-spade frankness, whereas tuberculosis has become a stigma disease, the mention of which conjures up terrifying pictures of infection, not to say contagion. The lurid colouring of such pictures has been not a little enhanced by the injudicious daubing of "compulsory segregation" heavily over the canvas. A useful corrective to this tendency is to be found in the recommendation by the American Medical Association that wards in general hospitals should be opened to tuberculous patients. This recommendation was prepared by the American National Tuberculosis Association in 1916, and its approval by the American Medical Association at its recent annual meeting at Boston marks a definite change in the attitude of the profession to this disease. It has been calculated that there are about two million known sufferers from tuberculosis in the U.S.A., quite apart from the thousands whose disease is incipient or latent and unknown. In this stage tuberculosis is often very difficult to detect, and to effect a certain diagnosis it is frequently desirable to admit the case to a hospital for a term of observation. But if this hospital be a special tuberculosis hospital, the person examined may emerge with the diagnosis of tuberculosis excluded, and yet he may not get rid of the stigma attaching to his sojourn in such a hospital. On the other hand, another person may actually be suffering from active tuberculosis in an early stage, but fear of the stigma of an avowed tuberculosis hospital may defer action till no action can secure his recovery. In a general hospital the diagnosis of tuberculosis does not become general knowledge, and the family need not be embarrassed by such knowledge. At the same time, all necessary precautions can be taken to avoid danger of infection to others. In further support of this new policy, it is said that in many small towns two hospitals, one general and one tuberculous, can be run only at a loss, whereas if combined they would pay working expenses, and the combined hospital would draw many secret tuberculous cases. A number of general hospitals could easily enlarge their facilities by fitting up porches and other open-air structures without great extra expense. The same arguments apply to the other stigma diseases, and great as is the importance of specialisation in the treatment of various diseases, this aspect must not blind us to the socio-psychological factor.

are admitted between 8.45 and 9.30 A.M., and are seen by the dental surgeon for the day, the staff demonstrator, the dental house surgeon, and the dressers. The Conservation Room is open from 9 A.M. till 5 P.M. It has recently been entirely remodelled and greatly enlarged, giving a floor space of over 6000 square feet. It affords accommodation for about 100 dental chairs, with the necessary equipment of the most modern type, for the use of the Dressers, who, under the supervision of the Staff, perform the various operations of Dental Surgery. The members of the staff attend every morning and afternoon to give demonstrations and otherwise assist students in their work in the Conservation Room and Prosthetic Laboratory. The Probationers' Laboratory is supervised by two of the staff demonstrators, and instruction is given in operative dentistry on a "mannikin" to students during their first three months of clinical study. Students in Dental Prosthetics are received, and a graded, systematic, and full course of instruction, extending over two years, is carried out. Dental students have the opportunity of attending at this hospital the whole course of instruction required by the examining board for the L.D.S. Eng.—viz., two years' studentship in dental prosthetics, the special lectures and practice of the Dental Department, and the general lectures and practice of the Medical School. The fees for these two courses may be paid separately or together, or they may be combined with the fees required to be paid for the course for a medical diploma. Students who enter for a medical as well as a dental diploma are allowed to pursue their study of Dentistry during any period of their medical course most convenient to themselves without further charge. Four Scholarships in Dental Prosthetics of the value of £30 each are offered for competition annually, two in September and two in April, and prizes of the aggregate value of £40 are awarded for general proficiency and for skill in Operative Dentistry. The Newland-Pedley Gold Medal for Operative Dentistry is also awarded annually. A Dental Travelling Scholarship of the value of £100 is awarded every second year. Dental students are eligible for admission to the Residential College and enjoy the privileges of students in the Medical School. Application should be made to the Dean of the Medical School.

London Hospital.—This school is a part of the London Hospital and Medical College, and is fully equipped on the most modern lines and with the latest appliances. It provides a complete curriculum in all subjects for the L.D.S. Diploma, and is admirably adapted for the purpose of teaching. The Conservation Room is well lighted and ventilated and fitted with pump chairs of the latest pattern; the fountain spittoon at every chair has been specially designed and has attached to it a saliva ejector, hot and cold water, compressed air, gas and electric current, also a swing bracket to carry the students' cabinet. Electric sterilisers are supplied in each department and motor engines where required. The School possesses in addition to the Theatres, Laboratories and Museums in the College, a special Museum of Dental Anatomy and Surgery, Operative Dentistry, Prosthetic and Extraction Rooms, and Laboratories for Practical Dental Metallurgy and Dental Prosthesis. A systematic course of instruction in Dental Prosthesis is arranged for pupils. The up-to-date Laboratory contains every modern apparatus and is in charge of a skilled curator and his assistants. Connected with the Medical College and Dental School are a Library, Athenæum, Clubs' Union, Dining Hall with moderate tariff, Students' Hostel, and an Athletic Ground. For full particulars as to fees and course of study advised apply to the Dean, Prof. William Wright, who will be glad to make arrangements for anyone wishing to see the Dental School and Medical College.

London (Royal Free Hospital) School of Medicine for Women.—Full courses are arranged for women students for the study of dentistry, and in preparation for the Licence in Dental Surgery of the Royal College of Surgeons of England, at the London (Royal Free Hospital) School of Medicine for Women, in conjunction with the London Dental Hospital, Leicester-square. The course is arranged as follows: First and second years: Chemistry, Physics, and Dental Mechanics. Third and fourth years: Anatomy, Physiology, and Special Dental Courses, Courses in Medicine and Surgery, General Hospital Course, Dental Hospital Course.

PROVINCIAL.

Birmingham Dental Hospital, Great Charles-street.—Dean: Mr. W. T. Madin. The Dental Hospital was founded in 1858, and was recognised by the Royal College of Surgeons in 1880 for the teaching of Dental Students. Having an annual attendance of about 10,000 patients, it affords every advantage for students about to enter the profession to acquire a thorough practical knowledge, as required by the Medical Council. The present Hospital was opened on July 6th, 1905. It has accommodation for 50 students. The equipment is in accordance with the most modern requirements for the efficient teaching and practice of Dental Surgery. The operations performed annually average 35,000, including 5000 gold and other fillings, and many cases of crowns, bridges, porcelain inlays, and regulations. By arrangements with the Birmingham University and with the General and Queen's Hospitals the entire course of Lectures, Hospital Practice, &c., may be completed for an inclusive fee of £121 14*s.* 6*d.*, or including Mechanical Pupilage, £233 5*s.* 9*d.* Examination fees for L.D.S. Birm., total £22 10*s.* The instruments and materials necessary for Hospital Practice cost about £35. The Composition Fee for the courses required for the L.D.S. of the University, or any of the Corporations alone, is £75, payable in two annual instalments at the commencement of the first and second years; that for the courses required for the L.D.S. and the Degree in Dentistry of the University is £100; that for the L.D.S. in combination with the M.R.C.S. and L.R.C.P. is £106 5*s.*; and that for the M.B., Ch. B., and B.D.S. is £118 15*s.* All of these composition fees are payable in two annual instalments at the commencement of the first and second years. Each of these fees covers the cost of the courses given at the University for the qualifications indicated, but does not include fees for Hospital teaching. For two years' dental hospital practice the fee is £26 5*s.*, payable in two instalments of £13 2*s.* 6*d.* each at the commencement of the first and second (hospital) years respectively. For two years' mechanical pupilage, £111 11*s.* 3*d.*, which may be paid in two annual instalments of £65 12*s.* 6*d.* and £45 18*s.* 9*d.* respectively; mechanical pupils may join for a probationary period of one month, fee £8 11*s.* 3*d.*, which is deducted upon payment of the full amount. For general surgical hospital practice, lectures, and demonstrations: Surgery, two winters, £13 2*s.* 6*d.* One Entrance Scholarship is offered annually of the value of £37 10*s.* It is awarded to the student who, entering for the Dental Degree of the University in October, or having entered not earlier than the previous April, shall pass the best examination in the subjects studied during his apprenticeship. Candidates must be under the age of 21 years. Application for admission, together with a certificate of birth, must be sent to the Dean of the Medical Faculty, Mr. William F. Haslam, on or before Oct. 15th.

Leeds University School of Dentistry.—The School of Dentistry is fully equipped to provide training for Dental Students, and affords every opportunity for the student to prepare for any of the Dental Degrees or Diplomas. The Demonstrator of Operative Dental Surgery instructs students during their probationary course. At the completion of this training students have patients allotted to them by the Demonstrator, and have every opportunity of acquiring knowledge from the members of the Honorary Staff, two of whom are in attendance each day. The following prizes are awarded:—First year Students, value 2 guineas. Operative Dental Surgery Prize, value 5 guineas. Two prizes in Prosthetic Dentistry: (*a*) a prize, value 2 guineas, for first year pupils; (*b*) a prize, value down of proteins by putrefactive bacilli are harmful when administered by the *mouth*, and that the whole conception is based upon injections under the skin.

It is well attested that in the majority of food-poisoning outbreaks the food is perfectly good in appearance, taste, and smell, and that evidences of decomposition are usually conspicuously absent. On the positive side all outbreaks, or at least all the larger ones which have been scientifically investigated, have been traced to the activities of specific bacilli, nearly all of them members of the salmonella group. While this point has been definitely established it still leaves very many factors in their causation unexplained. One essential problem which has to be solved is as to the source and channels whereby the infecting bacilli gain access to the food. It is this vital factor that most of the recorded outbreaks leave undecided. In a very few instances a human source of infection has been detected; this was the case in the Lambeth outbreak investigated by Dr. J. Priestley in Aug. 1920.[1] In a considerable number (especially on the Continent, where food supervision is more thorough) the food has been traced back to a diseased animal, but in the majority there is no evidence at all as to any source of infection. This cannot be ascribed to the use of meat from a diseased animal but unrecognised as such, since in many cases the evidence is convincing that the animal was healthy and infection was subsequent to slaughter. In some cases the food is not of animal origin at all; in others it was harmless at first and only poisonous subsequently. The sources of infection in these outbreaks can only be unravelled by searching and elaborate investigation of all channels of infection. In this and other directions there are many gaps in our knowledge and until they are bridged the prevention of these distressing outbreaks is likely to remain in its present unsatisfactory state.

This being the present position of our knowledge we welcome the arrangements which have been made recently between the Ministry of Health and the Medical Research Council for the fuller investigation of the conditions which give rise to illness produced by bacterial food poisoning. The inquiry will be undertaken by medical officers of the Foods Section of the Ministry, under the direction of Dr. A. W. J. MacFadden, in coöperation with Dr. W. G. Savage, under whom the investigations will be made at the University of Bristol by a special investigator. Medical officers of health and medical men are invited to make use of these facilities for the investigation of outbreaks through Dr. MacFadden or Dr. Savage at Weston-super-Mare. We reprint on p. 727, for the convenience of readers, the instructions given in the circular of the Ministry of Health for the collection and transmission of specimens to the laboratory.

CHEMICAL WARFARE.
